A
NEW CYCLOPÆDIA,

COMPREHENDING
A COMPLETE SERIES OF
Essays, Treatises, and Systems,
ALPHABETICALLY ARRANGED;
WITH A GENERAL DICTIONARY OF
ARTS, SCIENCES, AND WORDS:
THE WHOLE
PRESENTING A DISTINCT SURVEY OF
Human Genius, Learning, and Industry.
ILLUSTRATED WITH
ELEGANT ENGRAVINGS;
THOSE ON NATURAL HISTORY BEING FROM ORIGINAL DRAWINGS BY EDWARDS AND OTHERS, AND BEAUTIFULLY COLOURED AFTER NATURE.

BY JOHN MASON GOOD, ESQ. F.R.S.
MEMBER OF THE AMERICAN PHILOSOPHICAL SOCIETY, AND OF THE LINNEAN SOCIETY OF PHILADELPHIA;
OLINTHUS GREGORY, LL. D.
OF THE ROYAL MILITARY ACADEMY, WOOLWICH, AND HONORARY MEMBER OF THE LITERARY AND PHILOSOPHICAL SOCIETY, NEWCASTLE-UPON-TYNE; AND
MR. NEWTON BOSWORTH,
OF CAMBRIDGE;
ASSISTED BY OTHER GENTLEMEN OF EMINENCE, IN DIFFERENT DEPARTMENTS OF LITERATURE.

VOL. VIII.
MID — OZO.

LONDON:
PRINTED FOR G. KEARSLEY; J. WALKER; J. STOCKDALE; R. LEA; E. JEFFERY; CROSBY AND CO.; SHERWOOD, NEELY, AND JONES; SUTTABY, EVANCE, AND CO.; J. BLACKLOCK; W. LOWE; J. BOOTH; J. RODWELL; BELL AND BRADFUTE, EDINBURGH; BRASH AND REID, GLASGOW; AND M. KEENE, DUBLIN.

1813.

PANTOLOGIA.

MI'DWINTER. *s.* (*mid* and *winter.*) The winter solstice (*Dryden*).

MIEGIA, in botany, a genus of the class triandria, order monogynia. Calyx two-valved, one-flowered; corol two-valved; nectary one-valved, involving the germ. One species, a grass of South America.

MIEL (Jan), a Flemish painter, born in 1599. He was the disciple of Gerard Segers, after which he went to Italy, where he greatly improved himself. His pictures of huntings are greatly admired, the figures and the animals being accurately drawn, and with much spirit. He died in 1664.

MIEN. *s.* (*mine,* Fr.) Air; look; manner (*Dryden*).

MIERIS (Francis), or the Elder, was a disciple of Gerard Douw, and born at Leyden in 1635. He imitated his master with great exactness, and his pictures are now extremely scarce and valuable. He died in 1681.

MIERIS (William), the son of the preceding, was born at Leyden in 1662. He painted historical subjects, and also landscapes with animals, in an excellent style. He was likewise a good modeller in clay and wax. He died in 1747. His son Francis was a good artist, and painted in the same manner as his father.

MIEZA, in ancient geography, a town of Macedonia, situated near Stagira.

MIGHT. The preterit of *may*.

MIGHT. *s.* (mıȝhꞇ, Saxon.) Power; strength; force (*Ayliffe*).

MIGHT *and main.* Utmost force; highest degree of strength (*Dryden*).

MI'GHTILY. *ad.* (from *mighty.*) 1. With great power; powerfully; efficaciously; forcibly (*Hooker*). 2. Vehemently; vigorously; violently (*Shakspeare*). 3. In a great degree; very much (*Spectator*).

MI'GHTINESS. *s.* (from *mighty.*) Power; greatness; height of dignity (*Shakspeare*).

MI'GHTY. *a.* (from *might.*) 1. Strong; valiant (*Milton*). 2. Powerful (*Genesis*). 3. Impetuous; violent (*Isaiah*). 4. Vast; enormous; bulky (*Milton*). 5. Excellent; of superior eminence (*Dryden*). 6. Forcible; efficacious (*Esdras*).

MI'GHTY. *ad.* In a great degree (*Prior*).

MIGMA. (from μιγνυω, to mix). A confect, ointment, or mass of things mixed together.

MIGNARD (Nicholas), a French painter, born at Troyes about 1608 He became rector of the academy of painting at Paris. He excelled in painting historical subjects and portraits. He died in 1668.

MIGNARD (Peter), called the Roman from his long residence at Rome, was the brother of the preceding, and born in 1610. He is allowed to have been a superior artist to Nicholas, and was ennobled by Louis XIV. whose portrait he painted several times. He died in 1695.

MIGNON (Abraham), a painter, born at Frankfort in 1639. He painted flowers, insects, fruit, and still life, after nature, with wonderful exactness. He died in 1679.

MIGNONETTE, in botany. See RESEDA.

MIGRATION. *s.* (*migratio,* Latin.) 1. Act of changing residence (*Brown*). 2. Change of place; removal (*Woodward*).

MIGRATION OF SOULS. See METEMPSYCHOSIS and TRANSMIGRATION.

MIGRATION OF BIRDS. It is believed that many different kinds of birds annually pass from one country to another, and spend the summer or the winter where it is most agreeable to them; and that even the birds of our own island will seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long been an opinion pretty generally received, that swallows reside during the winter-season in the warm southern regions; and Mr. Adanson particularly relates his having seen them at Senegal, when they were obliged to leave this country. But besides the swallow, Mr. Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain. The reason of these migrations he supposes to be a defect of food at certain seasons of the year, or the want of a secure asylum from the persecution of man during the time of courtship, incubation, and nutrition. The following is his list of the migrating species.

1. Crows.—Of this genus, the hooded crow migrates regularly with the woodcock. It inhabits North Britain the whole year: a few are said annually to breed on Dartmoor in Devonshire. It breeds also in Sweden and Austria: in some of the Swedish provinces it only shifts its quarters, in others it resides throughout the year. Our author is at a loss for the summer retreat of those which visit us in such numbers in winter, and quit our country in the spring; and for the reason why a bird, whose food is such that it may be found at all seasons in this country, should leave us.

2. Cuckoo.—Disappears early in autumn; the retreat of this and the following bird is quite unknown to us.

3. Wryneck.—Is a bird that leaves us in the winter. If its diet be ants alone, as several assert, the cause of its migration is very evident. This bird disappears before winter, and revisits us in the spring, a little earlier than the cuckoo.

4. Hoopoe.—Comes to England but by accident: Mr. Pennant once indeed heard of a pair that attempted to make their nest in a meadow at Selborne, Hampshire, but were frightened away by the curiosity of people. It breeds in Germany.

5. Grous.—The whole tribe, except the quail, lives here all the year round: that bird either leaves us, or else retires towards the sea-coasts.

6. Pigeons.—Some few of the ring-doves breed here; but the multitude that appears in the winter is so disproportioned to what continue here the whole year, as to make it certain that the greatest part quit the country in the spring. It is most probable they go to Sweden to breed, and return from thence in autumn; as Mr. Ekmark informs us, they entirely quit that country before winter. Multitudes of the common wild pigeons also make the northern retreat, and visit us in winter; not but numbers breed in the high cliffs in all parts of this island. The turtle also probably leaves us in the winter, at least changes its place, removing to the southern counties.

7. Stare.—Breeds here. Possibly several remove to other countries for that purpose, since the produce of those that continue here seems unequal to the clouds of them that appear in the winter. It is not unlikely that many of them migrate into Sweden, where Mr. Berger observes they return in spring.

8. Thrushes.—The fieldfare and the redwing breed and pass their summers in Norway and other cold countries; their food is berries, which abounding in our kingdoms tempt them here in the winter. These two, and the Royston crow, are the only land birds that regularly and constantly migrate into England, and do not breed here. The hawfinch and crossbill come here at such uncertain times as not to deserve the name of birds of passage.

9. Chatterer.—The chatterer appears annually about Edinburgh in flocks during winter, and feeds on the berries of the mountain-ash. In South Britain it is an accidental visitant.

10. Grosbeaks.—The grosbeak and crossbill come here but seldom; they breed in Austria. The pine grosbeak probably breeds in the forests of the highlands of Scotland.

11. Buntings.—All the genus inhabits England throughout the year, except the greater brambling, which is forced here from the north in very severe seasons.

12. Finches.—All continue in some parts of these kingdoms, except the siskin, which is an irregular visitant, said to come from Russia. The linnets shift their quarters, breeding in one part of this island, and remove with their young to others. All finches feed on the seeds of plants.

13. Larks, Fly-catchers, Wagtails and Warblers.—All of these feed on insects and worms; yet only part of them quit these kingdoms, though the reason of migration is the same to all. The nightingale, black cap, fly-catcher, willow-wren, wheat-ear, and white-throat, leave us before winter, while the small and delicate golden-crested wren braves our severest frosts. The migrants of this genus continue longest in Great Britain in the southern counties, the winter in those parts being later than in those of the north; Mr. Stillingfleet having observed several wheat-ears in the isle of Purbeck on the 18th of November. As these birds are incapable of very distant flights, Spain, or the south of France, is probably their winter-asylum.

14. Swallows and Goat-sucker.—Every species disappears at the approach of winter.

WATER-FOWL.

Of the vast variety of water-fowl that frequent Great Britain, it is amazing to reflect how few are known to breed here: the cause that principally urges them to leave this country seems to be not merely the want of food, but the desire of a secure retreat. Our country is too populous for birds so shy and timid as the bulk of these are. when great part of our island was a mere waste, a tract of woods and fen, doubtless many species of birds (which at this time migrate) remained in security throughout the year. Egrets, a species of heron, now scarce known in this island, were in former times in prodigious plenty; and the crane, that has totally forsaken this country, bred familiarly in our marshes; their place of incubation, as well as of all other cloven-footed water-fowl (the heron excepted), being on the ground, and exposed to every one. As rural economy increased in this country, these animals were more and more disturbed; at length, by a series of alarms, they were necessitated to seek, during the summer, some lonely safe habitation.

On the contrary, those that build or lay in the almost inaccessible rocks that impend over the British seas breed there still in vast numbers, having little to fear from the approach of mankind: the only disturbance they meet with in general being from the desperate attempts of a few to get their eggs.

Cloven-footed Water-Fowl.

15. Herons.—The white heron is an uncommon bird, and visits us at uncertain seasons; the common kind and the bittern never leave us.

16. Curlews.—The curlew breeds sometimes on our mountains, but considering the vast flights that appear in winter, it is probable that the greater part retire to other countries: the whimbrel breeds on the Grampian hills, in the neighbourhood of Invercauld.

17. Snipes.—The woodcock breeds in the moist woods of Sweden and other cold countries. Some snipes breed here, but the greatest part retire elsewhere; as do every other species of this genus.

18. Sandpipers.—The lapwing continues here the whole year; the ruff breeds here, but retires in winter; the redshank and sandpiper breed in this country and reside here. All the others absent themselves during summer.

19. Plovers and Oyster-catcher.—The long-legged plover and sanderling visit us only in winter; the dottrel appears in spring and in autumn; yet, what is very singular, we do not find it breeds, in South Britain. The oyster-catcher lives with us the whole year. The Norfolk plover and sea-lark breed in England. The green plover breeds on the mountains of the north of England, and on the Grampian hills.

We must here remark, that every species of the genera of curlews, woodcocks, sandpipers, and plovers, that forsake us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed: as soon as the young can fly, they return to us again, because the frosts which set in early in those countries totally deprive them of the means of subsisting; as the dryness and hardness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills, in search of worms, which are the natural food of these birds. Mr. Ekmark speaks thus of the retreat of the whole tribe of cloven-footed water-fowl out of his country (Sweden) at the approach of winter; and Mr. Klein gives much the same account of those of Poland and Prussia.

20. Rails and Gallinules.—Every species of these two genera continue with us the whole year; the land rail excepted, which is not seen here in winter. It likewise continues in Ireland only during the summer-months, when they are very numerous, as Mr. Smith tells us in the History of Waterford, p. 336. Great numbers appear in Anglesea the latter end of May; it is supposed that they pass over from Ireland, the passage between the two islands being but small. As we have instances of these birds lighting on ships in the Channel and the Bay of Biscay, we may conjecture their winter-quarters to be in Spain.

Finned-footed Water-Birds.

21. Phalaropes.—Visit us but seldom; their breeding place is Lapland, and other arctic regions.

22. Grebes.—The great-crested grebe, the black and white grebe, and the little grebe, breed with us, and never migrate; the others visit us accidentally, and breed in Lapland.

Web-footed Birds.

23. Avoset.—Breed near Fossdike in Lincolnshire, but quit their quarters in winter. They are then shot in different parts of the kingdom, which they visit, not regularly, but accidentally.

24. Auks and Guillemots.—The great auk or penguin sometimes breeds in St. Kilda. The auk, the guillemot, and puffin, inhabit most of the maritime cliffs of Great-Britain, in amazing numbers during summer. The black guillemot breeds in the Bass Isle, and in St. Kilda, and sometimes in Llandidno rocks. We are at a loss for the breeding-place of the other species; neither can we be very certain of the winter residence of any of them, excepting of the lesser guillemot and black-billed auk, which, during winter, visit in vast flocks the Frith of Forth.

25. Divers.—These chiefly breed in the lakes of Sweden and Lapland, and in some countries near the pole; but some of the red-throated divers, the northern and the imber, may breed in the north of Scotland and its isles.

26. Terns.—Every species breeds here; but leaves us in the winter.

27. Petrels.—The fulmar breeds in the isle of St. Kilda, and continues there the whole year except September and part of October. The shearwater visits the isle of Man in April; breeds there; and, leaving it in August or the beginning of September, disperses over all parts of the Atlantic ocean. The stormfinch is seen at all distances from land on the same vast watery tract; nor is ever found near the shore except by some very rare accident, unless in the breeding season. Mr. Pennant found it on some little rocky isles on the north of

Skye. It also breeds on St. Kilda. He also suspects that it nestles on the Blasquet isles off Kerry, and that it is the gourder of Mr. Smith.

28. Mergansers.—This whole genus is mentioned among the birds that fill the Lapland lakes during summer. Mr. Pennant has seen the young of the red-breasted in the north of Scotland: a few of these, and perhaps of the goosanders, may breed there.

29. Ducks.—Of the numerous species that form this genus, we know of few that breed here: the swan and goose, the shield-duck, the eider-duck, a few shovellers, garganies, and teals, and a very small portion of the wild ducks.

The rest contribute to form that amazing multitude of water-fowl that annually repair from most parts of Europe to the woods and lakes of Lapland and other arctic regions, there to perform the functions of incubation and nutrition in full security. They and their young quit their retreat in September, and disperse themselves over Europe. With us they make their appearance the beginning of October; circulate first round our shores; and, when compelled by severe frost, betake themselves to our lakes and rivers. Of the web-footed fowl there are some of hardier constitutions than others: these endure the ordinary winters of the more northern countries; but when the cold reigns there with more than common rigour, they repair for shelter to these kingdoms: this regulates the appearance of some of the diver kind, as also of the wild swans, the swallow-tailed shield-duck, and the different sorts of goosanders which then visit our coasts. Barentz found the barnacles with their nests in great numbers in Nova Zembla. (Collect. Voy. Dutch East India Company, 8vo. 1703, p. 19.) Clusius, in his Exot. 368. also observes, that the Dutch discovered them on the rocks of that country and in Waygate Straits. They, as well as the other species of wild geese, go very far north to breed, as appears from the histories of Greenland and Spitzbergen, by Egede and Crantz. These birds seem to make Iceland a resting-place, as Horrebow observes: few continue there to breed, but only visit that island in the spring, and after a short stay retire still further north.

30. Corvorants.—The corvorant and shag breed on most of our high rocks: the gannet in some of the Scotch isles, and on the coast of Kerry: the two first continue on our shores the whole year. The gannet disperses itself all round the seas of Great Britain, in pursuit of the herring and pilchard, and even as far as the Tagus to prey on the sardina.

But of the numerous species of fowl here enumerated, it may be observed how very few entrust themselves to us in the breeding season, and what a distant flight they make to perform the first great dictate of nature.

There seems to be scarcely any but what we have traced to Lapland, a country of lakes, rivers, swamps, and alps, covered with thick and gloomy forests, that afford shelter during summer to these fowls, which in winter disperse over the greatest part of Europe. In those arctic regions, by reason of the thickness of the woods, the ground remains moist and penetrable to the woodcocks, and other slender-billed fowl; and for the web-footed birds, the waters afford larves innumerable of the tormenting gnat. The days there are long; and the beautiful meteorous nights indulge them with every opportunity of collecting so minute a food, whilst mankind is very sparingly scattered over that vast northern waste.

Why then should Linnéus, the great explorer of these rude deserts, be amazed at the myriads of water-fowl that migrated with him out of Lapland? which exceeded in multitude the army of Xerxes; covering for eight whole days and nights the surface of the river Calix! His partial observation as a botanist would confine their food to the vegetable kingdom, almost denied to the Lapland waters; inattentive to a more plenteous table of insect food, which the all-bountiful Creator had spread for them in the wilderness. It may be remarked, that the lakes of mountainous rocky countries in general are destitute of plants: few or none are seen on those of Switzerland; and Linnéus makes the same observation in respect to those of Lapland, having during his whole tour discovered only a single specimen of a lemma trisulca, or ivy-leaved duck's meat, Flora Lap. No. 470; a few of the scirpus lacustris, or bullrush, No. 18; the alopecurus geniculatus, or flote foxtail grass, No. 38; and the ranunculus aquatilis, No. 234; which are all he enumerates in his Prolegomena to that excellent performance.

MIKANIA. In botany, a genus of the class syngenesia, order polygamia æqualis. Receptacle naked; calyx four or six-leaved; four or six-flowered; down simple. Fourteen species; natives of the East or West Indies; one or two of Sierra Leone; some with scandent, others with erect, stems.

MILAN, a city of Italy, capital of a duchy of the same name. It was the ancient capital of Lombardy; and although it is thought rather to exceed Naples in size, it does not contain above half the number of inhabitants. It is seated in a delightful plain, between the rivers Adda and Tesin; is 10 miles in circumference, and called by the Italians, Milan the Great. It contains many fine palaces, but that of the governor is the most magnificent: and a great number of churches, convents, hospitals, and schools. The cathedral is in the centre of the city, and, next to St. Peter's at Rome, is the most considerable in Italy. The number of statues, within and without, is prodigious; they are all of marble, and many of them finely wrought. This vast fabric, which the Milanese call the eighth wonder of the world, is entirely built of solid white marble, and supported by fifty columns. From the roof hangs a case of crystal, inclosing a nail, which, they say, is one of those by which our Saviour was fixed to the cross. The treasury belonging to this church is reckoned the richest in Italy, next to that of Loretto. The college of St. Ambrose has a library, which, besides a prodigious number of manuscripts, contains 45,000 printed books; and its superb gallery is adorned with rich paintings. Milan has considerable commerce in grain (especially rice), cattle, and cheese; and has manufactures of silk and velvet stuffs, stockings, handkerchiefs, ribands, gold and silver lace and embroideries, woollen and linen cloths, glass, and earthenware in imitation of China. It has been several times taken in the wars that have desolated Italy; the last time by the French, in June 1796. It is the see of an archbishop; and is 70 miles north of Genoa, 72 north-east of Turin, and 145 north-west of Florence. Lon. 9. 16 E. Lat. 45. 28 N.

MILAN, or MILANESE, a duchy of Italy, 150 miles long, and 78 broad; bounded on the N. by Swisserland and the country of the Grisons, on the E. by the republic of Venice and the duchies of Parma and Mantua, on the S. by the duchy of Parma and the territory of Genoa, and on the W. by Piedmont and Montferrat. The soil is every where fertile in corn, wine, fruits, rice, and olives. The rivers are the Secchia, Tesin, Adda, and Oglio; and it has several lakes, the principal of which are those of Maggiore, Como, and Lugano. This country having formerly been possessed by the French, next by the Spaniards, and afterward by the Germans, the troops of those nations have produced a style of manners, and stamped a character, in the inhabitants of this duchy, different from what prevails in any other part of Italy; and nice observers imagine they perceive in the manners of the Milanese the politeness, formality, and honesty imputed to those three nations, blended with the natural ingenuity of the Italians. This duchy was entirely overrun by the French in 1796, and formed the principal part of their Cisalpine republic. On the renewal of hostilities, however, in 1799, it was soon reconquered by the allies. At present it is at the disposal of the emperor of the French.

MILAZZO, a strong seaport of Sicily, in Val-di-Demona. It is divided into the upper and lower town; the upper is very strong, and the lower has a fine square, with a superb fountain. It is seated on a rock, on the W. side of a bay of the same name, 18 miles W. of Messina. Lon. 15. 34 E. Lat. 38. 12 N.

MILBORN-PORT, a borough in Somersetshire, which has no market, but sends two members to parliament. It has manufactures of woollen cloth, linen, and hosiery; and is seated on a branch of the Parret, two miles E. by N. of Sherborn, and 115 W. by S. of London. Lon. 2. 38 W. Lat. 50. 53 N.

MILBOURNE (Luke) an English divine, was A. M. and rector of St. Ethelburga in London. He published several single sermons, a poetical version of the Psalms, and several poems and pamphlets, for which Pope gives him a place in the Dunciad. He died in 1720.

MILCH. *a.* (from *milk.*) Giving milk (*Shakspeare*).

MILD. *a.* (milꝺ, Saxon.) 1 Kind; tender; good; indulgent; merciful; compassionate; clement (*Rogers*). 2. Soft; gentle; not violent (*Pope*). 3. Not acrid; not corrosive; not acrimonious; demulcent; assuasive (*Arbuthnot*). 4. Not sharp; mellow; sweet; having no mixture of acidity (*Davies*).

MILDENHALL, a town in Suffolk, with a market on Friday; seated on the Larke, a branch of the Ouse, 13 miles N. by E. of Newmarket, and 69 N.N.E. of London. Lon. 0. 26 E. Lat. 52. 29 N.

MILDEW, in botany. See MUCOR, and ŒCIDIUM.

To MI'LDEW. *v. a.* To taint with mildew (*Gay*).

MI'LDLY. *ad.* (from *mild.*) 1. Tenderly; not severely (*Dryden*). 2. Gently; not violently (*Bacon*).

MI'LDNESS. *s.* (from *mild.*) Gentleness; tenderness; mercy; clemency (*Addison*).

MILE, a measure of length or distance, containing eight furlongs. The English statute-mile is 80 chains, or 1760 yards; that is, 5280 feet. We shall here give a table of the miles in use among the principal nations of Europe, in geometrical paces, 60,000 of which make a degree of the equator.

	Geometrical paces.
Mile of Russia	750
of Italy	1000
of England	1200
of Scotland and Ireland	1500
Old league of France	1500
The small league, ibid.	2000
The mean league, ibid.	2500
The great league, ibid.	3000
Mile of Poland	3000
of Spain	3428
of Germany	4000
of Sweden	5000
of Denmark	5000
of Hungary	6000

MI'LESTONE. *s.* (*mile* and *stone.*) Stone set to mark the miles.

MILETO, an ancient town of Naples, in Calabria Ulteriore, with a bishop's see, five miles from Nicotera.

MILETS, anciently MILETUS, a town of Turkey in Asia, in Natolia, 64 miles S. of Smyrna. Lon. 27. 14 E. Lat. 38. 22 N.

MILETUS (anc. geog.), a town of Crete mentioned by Homer; but where situated does not appear. It is said to be the mother-town of Miletus in Caria, whither a colony was led by Sarpedon, Minos's brother, (Ephorus, quoted by Strabo.) Milesii, the people, (Ovid.)

MILETUS (anc. geog.), a celebrated town of Asia Minor, on the confines of Ionia and Caria. It was the capital city of all Ionia, and famous both for the arts of war and peace. It was situated about 10 stadia south of the mouth of the river Mæander, near the sea-coast. It was founded by a Cretan colony under Miletus, the companion of Bacchus; or (according to others) by Neleus the son of Codrus; or by Sarpedon a son of Jupiter. It has successively been called Lelegeis, Pithyusa, and Anactoria. The inhabitants, called Melesii, were very powerful, and long maintained an obstinate war against the kings of Lydia. They early applied themselves to navigation, and planted no less than 80 colonies, or (according to Seneca) 380, in different parts of the world. It was the only town that made head against Alexander, and with much difficulty taken. It gave birth to Thales.

Miletus, a son of Apollo, who fled from Crete to avoid the wrath of Minos, whom he meditated to dethrone. He came to Caria, where he built or conquered a city which he called by his own name.

MILFOIL, in botany. See Achillea.

MILFORD, a town of the state of Delaware, in the county of Sussex, seated at the source of a small river, 15 miles from the bay of Delaware, and 150 S. of Philadelphia.

Milford, a town of S. Wales, in Pembrokeshire, on the N. coast of Milford Haven. A company of quakers, from America, have formed a plan for establishing here a whale fishery in the southern seas. A new quay has been built, and a considerable number of buildings erected toward forming a town. It is six miles W.N.W. of Pembroke, and six S.S.W. of Haverfordwest.

Milford Haven, a deep inlet of the Irish sea, on the coast of Pembrokeshire. It branches off into so many creeks, secured from all winds, that it is esteemed the safest and most capacious harbour in Great Britain; but its remote situation greatly impairs its utility. At the entrance, on the W. point, called St. Ann's, is an old lighthouse and a blockhouse. Here the earl of Richmond, afterwards Henry VII. landed, on his enterprise against Richard III. A packet-boat sails hence every day, except Tuesday, for Waterford, in Ireland.

MILIANE, a town of the state of Algiers in Tremesen, with a castle. It is seated in a country fertile in oranges, citrons, and other fruits, the best in Barbary. Lon. 2. 35 E. Lat. 35. 15 N.

MILIARIA. (*miliaria*, from *milium*, millet: so called because the small pustules or vesicles upon the skin resemble millet-seed). Miliary fever. A genus of disease in the class pyrexia, and order exanthemata of Cullen; characterised by synochus: cold stage considerable: hot stage attended with anxiety and frequent sighing; perspiration of a strong and peculiar smell; eruption preceded by a sense of pricking, first on the neck and breast, of small red pimples, which in two days become white pustules, desquamate, and are succeeded by fresh pimples. For the eruption similar to miliaria, but unattended with fever. See Sudamina.

MI'LIARY. *a.* (*milium*, Lat. millet.) Small; resembling a millet-seed (*Cheyne*).

Miliary fever. A fever that produces small eruptions. See Medicine.

MI'LICE. *s.* (Fr.) Standing force (*Temple*).

MI'LITANT. *a.* (*militans*, Latin.) 1. Fighting; prosecuting the business of a soldier (*Spenser*). 2. Engaged in warfare with hell and the world. A term applied to the church of Christ on earth, as opposed to the church triumphant (*Rogers*).

MI'LITAR. Mi'litary. *a.* (*militaris*, Latin. *Militar* is now out of use.) 1. Engaged in the life of a soldier; soldierly (*Shakspeare*). 2. Suiting a soldier; pertaining to a soldier; warlike (*Prior*). 3. Effected by soldiers (*Bacon*).

Military tenures. See Tenure, Feodal system, and Knight.

Military ways (*viæ militares*), are the large Roman roads which Agrippa procured to be made through the empire in the time of Augustus, for the more convenient marching of troops and conveyance of carriages. N. Bergier has written the history of the origin, progress, and amazing extent of these military roads, which were paved from the gates of Rome to the extreme parts of the empire. See Way.

MILITIA, in general, denotes the body of soldiers, or those who make a profession of arms. In a more restrained sense, militia denotes the trained bands of a town or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or stated troops.

With us, however, militia signifies the national soldiery; the standing force of the nation.

It seems universally agreed by all historians, that king Alfred first settled a national militia in this kingdom, and by his prudent discipline made all the subjects of his dominions soldiers; but we are unfortunately left in the dark as to the particulars of this celebrated regulation

The feodal military tenures were established for the purpose of protection, and sometimes of attack against foreign enemies: (see this Dictionary, title Tenures.) For the further defence in cases of domestic insurrections or foreign invasions, various other plans have been adopted, all of them tending to unite the character of a citizen and soldier in one. First, The Assize of Arms, enacted 27 H. 2, and afterwards the stat. of Winchester, 13 E. 1. c. 6, obliged every man, according to his state and degree, to provide a certain quantity of such arms as were then in use; and it was part of the duty of constables under the latter statute to see such arms provided. These weapons were changed by stat. 4 & 5 P. & M. c. 2, into more modern ones; but both these provisions were repealed by stats. 1 Jac. 1. c. 25; 21 Jac. 1. c. 28. While these continued in force, it was usual, from time to time, for our princes to issue commissions of array; and send into every county officers in whom they could confide, to muster and array (or set in military order) the inhabitants of every district; and the form of the commission of array was settled in parliament, anno 5 Hen. 4, so as to prevent the insertion therein of any new penal clauses. Rushw. pt. 3. p. 662, 7. See 8 Rep. 375, &c. But it was also provided by stats. 1 E. 3. st. 2. cc. 5, 7: 25 E. 3. st. 5. c. 8, that no man should be compelled to go out of the kingdom at any rate, nor out of his shire, but in cases of urgent necessity; nor should provide soldiers unless by consent of parliament. About the reign of king Henry VIII, or his children, lieutenants began to be introduced, as standing representatives of the crown to keep the counties in military order; for we find them mentioned as known officers in the stat. 4 & 5 P. & M. c. 3, though they had then not been long in use; for Camden speaks of them in the time of queen Elizabeth, as extraordinary magistrates constituted only in times of difficulty and danger. But the introduction of these commissions of lieutenancy, which contained in substance the same powers as the old commissions of array, caused the latter to fall into disuse.

In this state things continued till the repeal of the statutes of armour in the reign of king James I.; after which, when king Charles I. had, during his northern expeditions, issued commissions of lieutenancy, and exerted some military powers, which having been long exercised, were thought to belong to the crown, it became a question in the long parliament, how far the power of the militia did inherently reside in the king; being now unsupported by any statute, and founded only upon immemorial usage. This question, long agitated with great heat and resentment on both sides, became at length the immediate cause of the fatal rupture between the king and his parliament: the two houses not only denying this prerogative of the crown, the legality of which might, perhaps, be somewhat doubtful; but also seizing into their own hands the entire power of the militia; the illegality of which step could never be any doubt at all.

Soon after the restoration of king Charles II. when the military tenures were abolished, it was thought proper to ascertain the power of the militia, to recognise the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination. And the order in which the militia now stands by law is principally built upon the stats. 13 C. 2. c. 6: 14 C. 2 c. 3: 15 C. 2. c. 4. which were then enacted. It is true, the two last of them are apparently repealed, but many of their provisions are re-enacted with the addition of some new regulations by the present militia laws: the general scheme of which is to discipline a certain number of the inhabitants of every county chosen by lot formerly for *three*, but now (by stat. 26 Geo. 3. c. 107) for *five* years, and officered by the lord lieutenant, the deputy lieutenants, and other principal landholders, under a commission from the crown. They are not compellable to march out of their counties unless in case of invasion or actual rebellion within the realm, (or any of his majesty's dominions or territories, stat. 16 Geo. 3. c. 3.) nor in any case compelled to march out of the kingdom. They are to be exercised at stated times; and their discipline in general is liberal and easy; but when drawn out into actual service, they are subject to the rigours of martial law, as necessary to keep them in order. This is the constitutional security which our laws have provided for the public peace, and for protecting the realm against foreign or domestic violence. See stats. 2 Geo. 3. c. 20: 9 Geo. 3. c. 42: 16 Geo. 3. c. 3: 18 Geo. 3. cc. 14, 59: 19 Geo. 3. c. 72: 26 Geo. 3. c. 107: and 1 Comm. 410, &c.

The act reducing into one all the laws relating to the militia is stat. 26 Geo. 3. c. 107. This mentions the particular quota of each county and district in England and Wales, the whole number amounting to 30,740. And it is by this act provided, that in cases of actual invasion or imminent danger thereof, and in cases of rebellion and insurrection, his majesty may embody the militia: and if parliament is not then sitting, they are to meet by proclamation in 14 days.

Subsequent acts have given rise to the supplementary militia, the local militia, &c. but we have not room to describe these acts here.

MILIUM, **Millet**, in botany, a genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the fourth order, Gramina. The calyx is bivalved and uniflorous; the corol is very short; the stigmata pencil-like. There are five species, of which the most remarkable is the panicum, or common millet. This is a native of India, but is now commonly cultivated in many parts of Europe as an esculent grain. It rises, with a reed-like stalk, three or four feet high, and channelled. at every joint there is one reed-like leaf, which is joined on the top of the sheath, and embraces and covers that joint of the stalk below the leaf; this sheath is closely covered with soft hairs, but the leaf which is expanded has none. The top of the stalk is terminated by a large loose panicle, which hangs on one side, having a chaffy flower, which is succeeded by a small round seed. There are two varieties; one with white, and the other with black seeds; but they do not differ in any other particular. This plant is greatly cultivated in the oriental countries, and from whence we are annually furnished with it. It is seldom cultivated in Britain, but in small gardens, for feeding of poultry, where the seeds generally ripen very well. It is used as an ingredient in puddings, and is by some people greatly esteemed. The seeds must be sown in the beginning of April, upon a warm dry soil, but not too thick, because the plants divide into several branches, and should have much room. When they come up, they should be cleansed from weeds; after which they will in a short time get the better of them, and prevent the future growth. In August the seeds will ripen, when the plant must be cut down, and the seeds beaten out, as is practised for other grain; but if it is not protected from birds, they will devour it as soon as it begins to ripen.

MILIUM. (*milium.*) Grutum. In medicine, a very white and hard tubercle, in size and colour resembling a millet-seed. Its seat is immediately under the cuticle, so that when pressed it escapes, the contents appearing of an atheromatous nature.

MILIUM SOLIS. See LITHOSPERMUM.

MILK. (*milch*, Germ. *lait*, Fr). A fluid secreted by peculiar glands, and designed to nourish young animals in the early part of their life. It is of an opaque white colour, a mild saccharine taste, and a slightly aromatic smell. It is separated immediately from the blood in the breasts or udders of female animals. Man, quadrupeds, and cetaceous animals are the only creatures which afford milk. All other animals are destitute of the organs which secrete this fluid. Milk differs greatly in the several animals.

This fluid, the next in importance of all the animal liquids to blood, has been examined very largely by different chemists, and its analysis is curious and important. Scheele, Fourcroy, and Vauquelin, Parmentier, Deyeux and many others have given particular attention to this subject, and from their united labours the following general account of its properties may be given.

Milk is a white opaque fluid, capable of moistening all substances that can be moistened by water: but its consistence is greater than that of water, and it is slightly unctuous: like water, it freezes when cooled down to about 30°; but Parmentier and Deyeux found that its freezing-point varies considerably in the milk of different cows, and even of the same cow at different times. Milk boils also when sufficiently heated; but the same variation takes place in the boiling-point of different milks, though it never deviates very far from the boiling-point of water. Milk is specifically heavier than water, and lighter than blood; but the precise degree cannot be ascertained, because almost every particular milk has a specific gravity peculiar to itself.

When milk is allowed to remain for some time at rest, there collects on its surface a thick unctuous yellowish-coloured substance, known by the name of cream. The cream appears sooner on milk in summer than in winter, evidently owing to the difference of temperature. In summer, about four days of repose are necessary before the whole of the cream collects on the surface of the liquid; but in winter it requires at least double the time.

After the cream is separated, the milk which remains is much thinner than before, and it has a blueish-white colour. If it is heated to the temperature of 100°, and a little rennet (which is water digested with the inner coat of a calf's stomach, and preserved with salt) is poured into it, coagulation ensues; and if the coagulum is broken, the milk very soon separates into two substances; a solid white part known by the name of curd, and a fluid part called whey.

Thus we see that milk may be easily separated into three parts; namely, cream, curd, and whey.

1. Cream is of a yellow colour, and its consistence increases gradually by exposure to the atmosphere. In three or four days it becomes so thick that the vessel which contains it may be inverted without risking any loss. In eight or ten days more, its surface is covered over with mucors and byssi, and it has no longer the flavour of cream, but of very fat cheese. This is the process for making what in this country is called a cream-cheese.

Cream possesses many of the properties of an oil. It is specifically lighter than water; it has an unctuous feel; stains clothes precisely in the manner of oil; and if it is kept fluid, it contracts at last a taste which is very analogous to the rancidity of oils. When kept boiling for some time, a little oil makes its appearance, and floats upon its surface. Cream is neither soluble in alcohol nor in oils. These properties are sufficient to shew us, that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with some serum; cream, then, is composed of a peculiar oil, curd, and serum. The oil may be easily obtained separate by agitating the cream for a considerable time. This process, known to every body, is called churning. After a certain time, the cream separates into two portions; one fluid, and resembling creamed milk; the other solid, and called butter.

Butter is of a yellow colour, possesses the properties of an oil, and mixes readily with other oily bodies. When heated to the temperature of 96°, it melts, and becomes transparent; if it is kept for some time melted, some curd and water, or whey, separates from it, and it assumes exactly the appearance of oil. But this process deprives it in a great measure of its peculiar flavour.

When butter is kept for a certain time, it becomes rancid, owing in a good measure to the presence of these foreign ingredients; for if butter is well washed, and a great portion of these matters separated, it does not become rancid nearly so soon as when it is not treated in this manner. It was formerly supposed that this rancidity was owing to the developement of a peculiar acid; but Parmentier and Deyeux have shewn that no acid is present in rancid butter. When butter is distilled, there comes over water an acid, and an oil, at first fluid, but afterwards concrete. The carbonaceous residuum is but small.

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow; but it is usual to allow cream to remain for some time before it is churned. Now cream, by standing, acquires a sour taste; butter, therefore, is commonly made from sour cream. Fresh cream requires at least four times as much churning before it yields its butter as sour cream does; consequently cream acquires, by being kept for some time, new properties, in consequence of which it is more easily converted into butter. When very sour cream is churned, every one who has paid the smallest attention must have perceived, that the buttermilk, after the churning, is not nearly so sour as the cream had been. The butter, in all cases, is perfectly sweet; consequently the acid which had been evolved has in a great measure disappeared during the process of churning. It has been ascertained, that cream may be churned, and butter obtained, though the contact of atmospheric air should be excluded. On the other hand, it has been affirmed, that when cream is churned in contact with air, it absorbs a considerable quantity of it.

In all cases there is a considerable extrication of gass during the churning of butter. From the phenomena, it can scarcely be doubted that this gass is carbonic acid. Dr. Young affirms, that during the churning there is an increase of temperature amounting to four degrees.

These facts shew that considerable chemical changes go on during the process of churning. The agitation keeps the different substances in contact, and enables them to act upon each other. The expulsion of carbonic acid accounts for the diminution of acidity after churning; while the other phenomena would lead us to suppose that the cream, before it becomes butter, unites to a new portion of oxygen.

The affinity of the oil of cream for the other ingredients is such, that it never separates completely from them. Not only are curd and whey always found in the cream, but some of this oil is constantly found in creamed milk and whey; for it has been ascertained by actual experiment, that butter may be obtained by churning whey. 27 Scotch pints of whey yield at an average about a pound of butter. This accounts for a fact well known to those who superintend dairies, that a good deal more butter may be obtained from the same quantity of milk, provided it is churned as drawn from the cow, than when the cream alone is collected and churned.

The buttermilk, as Parmentier and Deyeux ascertained by experiment, possesses precisely the properties of milk deprived of cream.

2. Curd, which may be separated from creamed milk by rennet, has many of the properties of coagulated albumen. It is white and solid; and when all the moisture is squeezed out, it has a good deal of brittleness. It is insoluble in water; but pure alkalies and lime dissolve it readily, especially when assisted by heat; and when fixed alkali is used, a great quantity of ammonia is emitted during the solution. The solution of curd in soda is of a red colour, at least if heat is employed; owing probably to the separation of charcoal from the curd by the action of the alkali. Indeed, when a strong heat has been used, charcoal precipitates as the solution cools. The matter dissolved by the alkali may be separated from it by means of an acid; but it has lost all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily stains on paper, and never acquires the consistence of curd. Hence it appears that curd, by the action of a fixed alkali, is decomposed, and converted into two new substances; ammonia, and oil, or rather fat.

Curd is soluble also in acids. If, over curd newly precipitated from milk, and not dried, there are poured eight parts of water, containing as much of any of the mineral acids as gives it a sensibly acid taste, the whole is dissolved after a little boiling. Acetic acid and lactic acid do not dissolve curd, when very much diluted; but these acids, when concentrated, dissolve it readily, and in considerable quantity. It is remarkable enough, that concentrated vegetable acids dissolve curd readily, but have very little action on it when they are very much diluted; whereas the mineral acids dissolve it when much diluted; but when concentrated, have either very little effect on it, as sulphuric acid, or decompose it, as nitric acid. By means of this last acid, as Berthollet discovered, a quantity of azotic gass may be obtained from curd.

Curd, as is well known, is used in making cheese; and the cheese is the better the more it contains of cream, or of that oily matter which constitutes cream. It is well known to cheesemakers, that the goodness of it depends in a great measure on the manner of separating the whey from the curd. If the milk is much heated, the coagulum broken in pieces, and the whey forcibly separated, as is the practice in many parts of Scotland, the cheese is scarcely good for any thing; but the whey is delicious, especially the whey last squeezed out, and butter may be obtained from it in considerable quantity. This is a full proof that nearly the whole creamy part of the milk has been separated with the whey. Whereas if the milk is not too much heated (about 100 degrees is sufficient), if the coagulum is allowed to remain unbroken, and the whey separated by very slow and gentle pressure, the cheese is excellent; but the whey is almost transparent, and nearly colourless.

Good cheese melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that good cheese contains a quantity of the peculiar oil which constitutes the distinguishing characteristic of cream; whence its flavour and smell.

This resemblance of curd and albumen makes it probable that the coagulation of milk and albumen depends upon the same cause. Heat, indeed, does not coagulate milk, because the curd in it is diluted with too large a quantity of water; but if milk is boiled in contact with air, a pellicle soon forms on its surface, which has the properties of curd. If this pellicle is removed, another succeeds; and by continuing the boiling, the whole of the curdy matter may be separated from milk. When this pellicle is allowed to remain, it falls at last to the bottom of the vessel; where being exposed to a greater heat, it becomes brown, and communicates to milk that disagreeable taste which, in this country, is called a singed taste. It happens more readily when milk is boiled along with rice, flour, &c.

If to boiling milk there is added as much of any neutral salt as it is capable of dissolving, or of sugar or of gum arabic, the milk coagulates and the curd separates. Alcohol also coagulates milk; as do all acids, rennet, and the infusion of the flowers of artichoke and of the thistle. If milk is diluted with ten times its weight of water, it cannot be made to coagulate at all.

3. Whey, after being filtered to separate a quantity of curd which still continues to float through it, is a thin pellucid fluid, of a yellowish-green colour and pleasant sweetish taste, in which the flavour of milk may be distinguished. It always contains some curd: nearly the whole may be separated by keeping the whey for some time boiling; a thick white scum gathers on the surface, which is known by the name of skim-curd. When this scum, which consists of the curdy part, is carefully separated, the whey, after being allowed to remain at rest for some hours, to give the remainder of the curd time to precipitate, is decanted off almost as colourless as water, and scarcely any of the peculiar taste of milk can be distinguished in it. If it is now slowly evaporated, it deposits at last a number of white-coloured crystals, which are sugar of milk. Towards the end of the evaporation, some crystals of muriat of potass and of muriat of soda make their appearance. According to Scheele, it contains also a little phosphat of lime, which indeed may be precipitated by ammonia.

After the salts have been obtained from whey, what remains concretes into a jelly on cooling. Hence it follows that whey also contains gelatine. Whey, then, is composed of water, sugar of milk, gelatine, muriat of potass, and phosphat of lime. The other salts which are sometimes found in it are only accidentally present.

If whey be allowed to remain for some time, it becomes sour, owing to the formation of a peculiar acid known by the name of lactic acid. It is to this property of whey that we are to ascribe the acidity which milk contracts; for neither curd nor cream, perfectly freed from serum, seems susceptible of acquiring acid properties. Hence the reason also that milk, after it becomes sour, always coagulates. Boiled milk has the property of continuing longer sweet, but it is singular enough that it runs sooner to putrefaction than ordinary milk.

The acid of milk differs considerably from the acetic: yet vinegar may be obtained from milk by a very simple process. If to somewhat more than 8lbs troy of milk six spoonfuls of alcohol are added, and the mixture well corked is exposed to a heat sufficient to support fermentation, provided attention is paid to allow the carbonic acid gass to escape from time to time, the whey, in about a month, will be found converted into vinegar.

Milk is almost the only animal substance which may be made to undergo the vinous fermentation, and to afford a liquor resembling wine or beer, from which alcohol may be separated by distillation. This singular fact seems to have been first discovered by the Tartars; they obtain all their spirituous liquors from mare's milk. It has been ascertained, that milk is incapable of being converted into wine till it has become sour; after this nothing is necessary but to place it in the proper temperature; the fermentation begins of its own accord, and continues till the formation of wine is completed. Scheele had shewed that milk was capable of fermenting, and that a great quantity of carbonic acid gass was extricated from it during this fermentation; but he did not suspect that the result of this fermentation was the formation of an intoxicating liquor similar to wine. The Tartars call the vinous liquid which they prepare kumiss. A very exact account of its preparation and medical uses has been published by Dr. Grieve. See the article KUMISS.

When milk is distilled by the heat of a water-bath, there comes over water having the peculiar odour of milk: which putrefies; and consequently contains, besides mere water, some of the other constituent parts of milk. After some time the milk coagulates, as always happens when hot albumen acquires a certain degree of concentration. There remains behind a thick unctuous yellowish-white substance, to which Hoffman gave the name of franchippan. This substance, when the fire is increased, yields at first a transparent liquid, which becomes gradually more coloured; some very fluid oil comes over, then ammonia, an acid, and at last a very thick black oil. Towards the end of the process carbureted hydrogen gass is disengaged. There remains in the retort a coal which contains carbonat of potass, muriat of potass, and phosphat of lime; and sometimes magnesia, iron, and muriat of soda.

Thus we see that cow's milk is composed of the following ingredients:

1. Water,
2. Oil,
3. Curd,
4. Gelatin,
5. Sugar of milk,
6. Muriat of soda,
7. Muriat of potass,
8. Sulphur,
9. Phosphat of lime.

The milk of all other animals, as far as it has hitherto been examined, consists nearly of the same ingredients; but there is a very great difference in their proportion; and we shall examine those differences, in the more important kinds, as succinctly as possible.

Human Milk.—This is secreted by the glandular fabric of the breast in women. The secretory organ is constituted by the great conglomerate glands situated in the fat of both breasts, above the musculus pectoralis major. From each acinus composing a mammary gland, there arises a radicle of a lactiferous or galactiferous duct. All these canals gradually converging, are terminated without anastomosis in the papillæ of the breasts by many orifices, which upon pressure pour forth milk. The smell of fresh drawn milk is peculiar, animal, fatuous, and not disagreeable. Its taste sweetish, soft, bland, agreeable. The specific gravity is greater than water, but lighter than blood; hence it swims on it. Its colour is white and opaque. In consistence it is oily and aqueous. A drop put on the nail flows slowly down, if the milk be good.

Time of Secretion.—The milk most frequently begins to be secreted in the last months of pregnancy; but on the third day after delivery, a serous milk called colostrum is separated; and at length pure milk is secreted very copiously into the breasts, that from its abundance, often spontaneously drops from the nipples.

If the secretion of milk be daily promoted by suckling an infant, it often continues many years, unless a fresh pregnancy supervene. The quantity usually secreted within twenty-four hours, by nurses, is various, according as the nourishment may be more or less chylous. It appears that not more than two pounds of milk are obtained from five or six pounds of meat. But there have been known nurses, who have given from their breasts two, or even more than three pounds, in addition to that which their child has sucked. That the origin of the milk is derived from chyle carried with the blood of the mammary arteries into the glandular fabric of the breasts, is evident from its more copious secretion a little after meals; its diminished secretion from fasting; from the smell and taste of food or medicines in the secreted milk: and lastly, from its spontaneous acescence; for humours perfectly animal become putrid.

The *milk of a woman* differs: 1. in respect of *food*. The milk of a woman who suckles, living upon vegeto-animal food, never acesces nor coagulates spontaneously, although exposed for many weeks to the heat of a furnace. But it evaporates gradually in an open vessel, and the last drop continues thin, sweet, and bland. The reason appears to be, that the caseous and cremoraceous parts cohere together by means of the sugar, more intimately than in the milk of animals, and do not so easily separate; hence its acescense is prevented. It does acesce, if mixed or boiled with vinegar, juice of lemons, cremor tartar, spirit of vitriol, or with the human stomach. It is coagulated with the acid of salt or nitre, and by the acid gastric juice of the infant; for infants often vomit up the coagulated milk of the nurse. The milk of a sucking woman who lives upon vegetable food only, like cows milk, easily and of its own accord acesces, and is acted upon by all coagulating substances like the milk of animals.—2. In respect of the *time of digestion*. During the first hours of digestion the chyle is crude, and the milk less subacted; but towards the twelfth hour after eating, the chyle is changed into blood, and then the milk becomes yellowish and nauseous, and is spit out by the infant. Hence the best time for giving suck is about the fourth or fifth hour after meals.—3. In respect of the *time after delivery*. The milk secreted immediately after delivery is serous, purges the bowels of the infant, and is called colostrum. But in the following days it becomes thicker and more pure, and the longer a nurse suckles, the thicker the milk is secreted; thus new-born infants cannot retain the milk of a nurse who has given suck for a twelvemonth, on account of its spissitude.—4. In respect of *food or medicines*. Thus if a nurse eat garlic, the milk becomes highly impregnated with its odour, and is disagreeable. If she indulge too freely in the use of wine or beer, the infant becomes ill. From giving a purging medicine to a nurse, the child also is purged; and lastly, children affected with tormina of the bowels, arising from acids, are often cured by giving the nurse animal food.—5. In respect of the *affections of the mind*. There are frequent examples of infants being seized with convulsions from sucking mothers irritated by anger. An infant of one year old, while he sucked milk from his enraged mother, on a sudden was seized with a fatal hæmorrhage and died. Infants at the breast in a short time pine away, if the nurse be afflicted with grievous care; and there are also infants who after every coition of the mother, or even if she menstruate, are taken ill.

The use of the mother's milk is, 1. It affords the native aliment to the new-born infant, in which respect milk differs little from chyle. Those children are the strongest who are nourished the longest by the mother's milk. 2. The colostrum should not be rejected; for it relaxes the bowels, which in new-born infants ought to be open, to clear their intestines of the meconium. 3. Lactation defends the mother from a dangerous reflux of the milk into the blood, whence lacteal metastasis and leucorrhæa are so frequent in lying-in women who do not give suck. The motion of the milk also being hastened through the breast by the sucking of the child, prevents the very common induration of the breast, which arises in consequence of the milk being stagnated. 4. Men may live upon milk, unless they have been accustomed to the drinking of wine. For all nations, the Japanese alone excepted, use milk, and many live upon it alone. Lastly, for many diseases, especially the gout, scurvy, dysentery, and phthisical tabes of the different viscera, a milk diet is reckoned amongst the most efficacious remedies.

Asses milk.—This more nearly resembles human milk than any other. The cream is in small quantity: by agitation it gives a butter, which is soft, white, and nearly tasteless. It soon becomes very rancid, owing probably to its retaining a portion of the acid. By standing it deposits much of the curd even before it becomes sour.

Goats milk.—This is very thick, yellowish, and pleasantly flavoured. It is somewhat denser than cow's milk; is remarkably thick and unctuous, and will keep a long time without growing sour, or sensibly changing. By agitation it gives a very firm, solid, and white butter. It abounds in curd: its sugar is small in quantity, but separates with ease.

Sheep's milk resembles cow's very closely in taste and appearance. It yields abundance of cream, which, by churning, affords much butter; but a butter that always remains soft. The quantity of curd is large, and it has a very fat and unctuous appearance, and a peculiar taste, which is always very distinguishable in ewe-milk cheese.

Mare's milk is thin and insipid, and does not coagulate with vinegar. It is remarkable for the small quantity of cream which it gives, and the extreme difficulty of separating the butter from it by agitation.

All these species of milk resemble each other essentially in the number and general chemical nature of the ingredients; but great diversity appears in their respective proportion, and, apparently, in the mode of their mixture. Thus, cow's and sheep's milk yield cream easily by repose, the consistence of which is greater than in the others, and the butter of which separates more perfectly. There is an equal difference in the consistence of the curd; that from cow's and sheep's milk being dense, and readily separating by the usual coagulating substances; while the curd from ass's and mare's milk always remains thin and of nearly a creamy consistence. The only general agreement which the authors of these experiments have been able to make on this subject is, that where the curd is tough and gelatinous the butter is readily separable from the cream, and all the constituent parts of the milk are more easily obtained by chemical means.

To MILK. *v. a.* (from the noun.) 1. To draw milk from the breast by the hand (*Pope*). 2. To suck (*Shakspeare*).

MILK-TEETH. See TEETH.

MILK-VETCH. In botany. See ASTRAGALUS.

MILK-WOOD. In botany. See BROSIMUM.

MILK-WORT. In botany. See POLYGALA.

MILK-THISTLE. See CARDUUS.

MI'LKEN. *a.* (from *milk.*) Consisting of milk (*Temple*).

MI'LKER. *s.* (from *milk.*) One that milks animals (*Dryden*).

MI'LKINESS. *s.* (from *milky.*) Softness like that of milk; approach to the nature of milk (*Floyer*).

MI'LKLIVERED. *a.* (*milk* and *liver.*) Cowardly; timorous; fainthearted (*Shaks.*).

MI'LKMAID. *s.* (*milk* and *maid.*) Woman employed in the dairy (*Addison*).

MI'LKMAN. *s.* (*milk* and *man.*) A man who sells milk.

MI'LKPAIL. *s.* (*milk* and *pail.*) A vessel into which cows are milked (*Watts*).

MI'LKPAN. *s.* (*milk* and *pan.*) Vessel in which milk is kept in the dairy (*Bacon*).

MILKPO'TTAGE. *s.* (*milk* and *pottage.*) Food made by boiling milk with water and oatmeal (*Locke*).

MI'LKSCORE. *s.* (*milk* and *score.*) Account of milk owed or scored on a board (*Addison*).

MI'LKSOP. *s.* (*milk* and *sop.*) A soft, mild, effeminate, feeble-minded man (*Spens.*).

MI'LKWHITE. *a.* (*milk* and *white.*) White as milk (*Dryden*).

MI'LKWOMAN. *s.* (*milk* and *woman.*) A woman whose business is to serve families with milk (*Arbuthnot*).

MI'LKY. *a.* (from *milk.*) 1. Made of milk. 2. Resembling milk (*Arbuthnot*). 3. Yielding milk (*Roscommon*). 4. Soft; gentle; tender; timorous (*Shakspeare*).

MILKY WAY, *Via Lactea*, or *Galaxy*, a broad track or path, encompassing the whole heavens, distinguishable by its white appearance, whence it obtains the name. It extends itself in some parts by a double path, but for the most part it is single. Its course lies through the constellations Cassiopeia, Cygnus, Aquila, Perseus, Andromede, part of Ophiucus and Gemini, in the northern hemisphere; and in the southern, it takes in part of Scorpio, Sagittarius, Centaurus, the Argo-navis, and the Ara. There are some traces of the same kind of light about the south pole, but they are small in comparison of this: these are called by some luminous spaces, and Magellanic clouds; but they seem to be of the same kind with the Milky way.

The Milky way has been ascribed to various causes. The ancients fabled, that it proceeded from a stream of milk, spilt from the breast of Juno, when she pushed away the infant Hercules, whom Jupiter laid to her breast to render him immortal. Some again, as Aristotle, &c. imagined that this path consisted only of a certain exhalation hanging in the air; while Metrodorus, and some Pythagoreans, thought the sun had once gone in this track, instead of the ecliptic; and consequently that its whiteness proceeds from the remains of his light. But it is now well known, by the help of telescopes, that this track in the heavens consists of an immense multitude of stars, seemingly very close together, whose mingled light gives this appearance of whiteness; by Milton beautifully described as a path "powdered with stars."

MILL. *s.* (*μυλη*; mÿln, Saxon.) An engine or fabric in which corn is ground to meal, or any other body is comminuted (*Sharp*).

To MILL. *v. a.* (from the noun; *μυ'λεῖν*) 1. To grind; to comminute. 2. To beat up chocolate. 3. To stamp coin in the mints (*Addison*).

The first obvious method of reducing corn into flour for bread would be, by the simple expedient of pounding. And that was for ages the only one which was practised by the various descendants of Adam, and actually continued in use among the Romans below the reign of Vespasian. But the process was very early improved by the application of a grinding power, and the introduction of mill-stones. This, like most of the common refinements in domestic life, was probably the invention of the antediluvian world, and certainly practised in some of the earliest ages after it. And like most of them, it was equally known in the east and west. Hence the Gauls and Britons appear familiarly acquainted with the use of hand-mills before the time of their submission to the Romans; the Britons particularly distinguishing them, as the Highlanders and we distinguish them at present, by the simple appellations of *querns, carnes*, or *stones*. And to these the Romans added the very useful invention of water-mills. For this discovery the world is pretty certainly indebted to the genius of Italy; and the machine was not uncommon in the country at the conquest of Lancashire. This, therefore, the Romans would necessarily introduce with their many other refinements among us. And that they actually did, the British appellation of a water-mill fully suggests of itself; the *melin* of the Welsh and Cornish, the *mull, meil*, and *melin* of the Armoricans, and the Irish *muilean* and *muilind*, being all evidently derived from the Roman *mola*, and *molendinum*. The subject Britons universally adopted the Roman name, but applied it, as we their successors do, only to the Roman mill; and one of these was probably erected at every stationary city in the kingdom. One plainly was at Manchester, serving equally the purposes of the town and the accommodation of the garrison. And one alone would be sufficient, as the use of hand-mills remained very common in both, many having been found about the site of the station particularly; and the general practice having descended among us nearly to the present period. Such it would be peculiarly necessary to have in the camp, that the garrison might be provided against a siege. And the water-mill at Manchester was fixed immediately below the castle-field and the town, and on the channel of the Medlock. There, a little above the ancient ford, the sluice of it was accidentally discovered about 30 years ago. On the margin of dyer's-croft, and opposite to some new constructions, the current of the river, accidentally swelled with the rains, and obstructed by a dam, broke down the northern bank, swept away a large oak upon the edge of it, and disclosed a long tunnel in the rock below. This has been since laid open in part with a spade. It appeared entirely uncovered at the top, was about a yard in width, and another in depth, but gradually narrowed to the bottom. The sides showed every where the marks of the tool on the rock, and the course of it was parallel with the channel. It was bared by the flood about twenty-five yards only in length, but was evidently continued for several further; having originally begun, as the nature of the ground evinces, just above the large curve in the channel of the Medlock.

For the first five or six centuries of the Roman state, there were no public bread-bakers in the city of Rome. They were first introduced into it from the east at the conclusion of the war with Perseus, and about the year 167 before Christ. And, towards the close of the first century, the Roman families were supplied by them every morning with fresh loaves for breakfast. But the same custom, which prevailed originally among the Romans and many other nations, has continued nearly to the present time among the Mancunians. The providing of bread for every family was left entirely to the attention of the women in it. And it was baked upon stones, which the Welsh denominate *greidiols*, and we *gredles*. It appears, however, from the kiln-burnt pottery which has been discovered in the British sepulchres, and from the British appellation of an *odyn* or *oven* remaining among us at present, that furnaces for baking were generally known among the original Britons. An odyn would, therefore, be erected at the mansion of each British baron, for the use of himself and his retainers: and when he and they removed into the vicinity of a Roman station, the oven would be rebuilt with the mansion, and the public bakehouses of our towns commence at the first foundation of them. One bakehouse would be constructed, as we have previously shown one mill to have been set up for the public service of all the Mancunian families. One oven and one mill appear to have been equally established in the town. And the inhabitants of it appear immemorially accustomed to bake at the one and grind at the other. Both, therefore, were in all probability constructed at the first introduction of water-mills and ovens into the country. The great similarity of the appointments refers the consideration directly to one and the same origin for them. And the general nature of all such institutions points immediately to the first and actual introduction of both. And, as the same establishments prevailed equally in other parts of the north, and pretty certainly obtained over all the extent of Roman Britain, the same erections were as certainly made at every stationary town in the kingdom.

For the description of different kinds of mills, see our articles CORN-MILL, BOLTING-MILL, FLOUR-MILL, OIL-MILL, ROLLING-MILL, WATER-MILL, WIND-MILL, &c.: and for the theory of mills, see the article MILL in Dr. Hutton's excellent Mathematical Dictionary; Gregory's Mechanics, vols. 1 and 2; Brewster's Ferguson; and Faber on Hydraulic Machines.

MILL (John), a learned English divine, born at Shap in Westmoreland, about 1645. In 1661 he was entered a servitor of Queen's college, Oxford, of which he afterwards became fellow. In 1681 he took his degree of D.D. and about the same time was appointed chaplain to the king. In 1685 he was elected principal of Edmund hall. His edition of the Greek Testament, which will carry his name down to the latest posterity, was published about a fortnight before his death, an event that happened in 1707.

Mill (Henry), principal engineer to the New River company, was born in London about 1680, and educated at one of the universities. His skill in mechanics recommended him to the New River company, in whose service he was for many years before his death in 1780. He was employed in various other works, particularly in supplying the town of Northampton with water, for which he received the freedom of that corporation.

Mill-cogs. *s.* The denticulations on the circumference of wheels, by which they lock into other wheels (*Mortimer*).

Mill-dam. *s.* The mound by which the water is kept up to raise it for the mill (*Mortimer*).

Mill-horse. *s.* Horse that turns a mill.

Mill-mountain. See Linum catharticum.

Mill-stone, in a mineralogical view, is a species of the aggregate earth named arenarius or sand-stone. See Arenarius.

MILLEA. In botany, a genus of the class hexandria, order monogynia. Corol funnel-form, with a six-parted, flat border; anthers inserted in the throat of the corol; germ pedicelled; capsule superior. One species: a Mexican plant, with large white corol.

MILLEFOLIUM. (*millefolium*, from *mille*, a thousand, and *folium*, a leaf; so named from its numerous leaves). See Melissa.

MILLEMORBIA. (*millemorbia*, from *mille*, a thousand, and *morbus*, a disease; so called from its use in many diseases.) See Scrophularia vulgaris.

MILLENA'RIAN. *s.* (from *millenarius*, Lat.) One who expects the millennium.

MI'LLENARY. *a.* (*millenarius*, Latin.) Consisting of a thousand (*Arbuthnot*).

MILLENER, or Milliner, one who sells ribbands and dresses, particularly head-dresses for ladies; and who makes up those dresses.

The derivation of this word is much disputed. It cannot be from the French, as some pretend; for the French express the notion of millener by the circumlocution *merchande des modes*.

Littleton, in his English and Latin dictionary, published 1677, defines millener, "a jack of all trades;" q. d. *millenarius*, or *mille mercium venditor*; that is, "one who sells a thousand different sorts of things." This etymology seems fanciful: but, if he rightly understood the vulgar meaning of the word millener in his time, we must hold that it then implied what is now termed "a haberdasher of small wares," one who dealt in various articles of petty merchandise, and who did not make up the goods which he sold.

Before Littleton's time, however, a somewhat nicer characteristic than seems compatible with his notion appears to have belonged to them; for Shakspeare, in his Henry IV. makes Hotspur, when complaining of the daintiness of a courtier, say, "He was perfumed like a millener." The fact seems to be, that there were milleners of several kinds: as, horse-milleners, (for so those persons were called who make ornaments of coloured worsted for horses); haberdashers of small wares, the milleners of Littleton; and milleners such as those now peculiarly known by that name, whether male or female, and to whom Shakspeare's allusion seems most appropriate.

Lastly, Dr. Johnson, in his Dictionary, derives the word from *milaner*, an inhabitant of Milan, from whence people of this profession first came, as a *Lombard* is a banker.

MI'LLENIST. *s.* (from *mille*, Latin.) One that holds the millennium.

MILLENNIUM, "a thousand years;" generally employed to denote the thousand years during which, according to an ancient tradition in the church, grounded on some doubtful texts in the Apocalypse and other scriptures, our blessed Saviour shall reign with the faithful upon earth after the first resurrection, before the final completion of beatitude. Though there has been no age of the church in which the millennium was not admitted by individual divines of the first eminence, it is yet evident from the writings of Eusebius, Irenæus, Origen, and others among the ancients, as well as from the histories of Dupin, Mosheim, and all the moderns, that it was never adopted by the whole church, or made an article of the established creed in any nation.

About the middle of the fourth century the millenarians held the following tenets: 1st, That the city of Jerusalem should be rebuilt, and that the land of Judea should be the habitation of those who were to reign on earth 1000 years. 2dly, That the first resurrection was not to be confined to the martyrs; but that after the fall of Antichrist all the just were to rise, and all that were on the earth were continue for that space of time. 3dly, That Christ shall then come down from heaven, and be seen on earth, and reign there with his servants. 4thly, That the saints during this period shall enjoy all the delights of a terrestrial paradise.

These opinions were founded upon several passages of scripture which the millenarians among the fathers understood in no other than a literal sense, but which the moderns, who hold that opinion, consider as partly literal and partly metaphorical. Of these passages, that upon which the greatest stress has been laid, we believe to be the following:—"And I saw an angel come down from heaven, having the key of the bottomless pit, and a great chain in his hand. And he laid hold on the dragon, that old serpent, which is the Devil and Satan, and bound him a thousand years, and cast him into the bottomless pit, and shut him up, and set a seal upon him, that he should deceive the nations no more till the thousand years should be fulfilled; and after that he must be loosed a little season. And I saw thrones, and they sat upon them, and judgment was given unto them: and I saw the souls of them that were beheaded for the witness of Jesus, and for the word of God, and which had not worshipped the beast, neither his image, neither had received his mark upon their foreheads, or in their hands; and they lived and reigned with Christ a thousand years. But the rest of the dead lived not again till the thousand years were finished. This is the first resurrection." Rev. xx. 1—6. This passage all the ancient millenarians took in a sense grossly literal: and taught, that during the millennium the saints on earth were to enjoy every bodily delight. The moderns, on the other hand, consider the power and pleasure of this kingdom as wholly spiritual; and they represent them as not to commence till after the conflagration of the present earth. But that this last supposition is a mistake, the very next verse except one assures us: for we are there told, that "when the thousand years are expired, Satan shall be loosed out of his prison, and shall go out to deceive the nations which are in the four quarters of the earth;" and we have no reason to believe that he will have such power or such liberty in "the new heavens and the new earth wherein dwelleth righteousness."

For this and other reasons, which our limits will not permit us to enumerate, the most judicious critics contend, that the prophecies of the millennium point not to a resurrection of martyrs and other just men to reign with Christ a thousand years in a visible kingdom upon earth, but to that state of the Christian church, which, for a thousand years before the general judgment, will be so pure and so widely extended, that, when compared with the state of the world in the ages preceding, it may, in the language of scripture, be called a resurrection from the dead. In support of this interpretation they quote two passages from St. Paul, in which a conversion from Paganism to Christianity, and a reformation of life, is called a resurrection from the dead:—"Neither yield ye your members as instruments of unrighteousness unto sin; but yield yourselves unto God as those that are alive from the dead." Rom. vi. 13. And again, "Wherefore he saith, Awake thou that sleepest, and arise from the dead, and Christ shall give thee light." Eph. v. 14. It is likewise to be observed, that in all the descriptions of the resurrection and future judgment which are given us at such length in the gospels and epistles, there is no mention made of a first and second resurrection at the distance of a thousand years from each other. There is indeed an order in the resurrection: for we are told (1 Cor. xv. 23.) that "every man shall rise in his own order; Christ the first fruits, afterwards they that are Christ's at his coming, &c." But were the millenarian hypothesis well founded, the words should rather have run thus. "Christ the first fruits, then the martyrs at his coming, and a thousand years afterwards the residue of mankind. Then cometh the end," &c.

These arguments strongly incline us to believe, that, by the reign of Christ and the saints for a thousand years upon earth, nothing more is meant than that before the general judgment the Jews shall be converted, genuine Christianity be diffused through all nations, and mankind enjoy that peace and happiness which the faith and precepts of the gospel are calculated to confer on all by whom they are sincerely embraced.

Our Saviour's own account of his religion is, that from a small beginning it will increase to the full harvest. The millennium therefore is to be considered as the full effect of the Christian principles in the hearts of men, and over the whole world; and the divines who have treated on this subject prove satisfactorily that this is to be expected from the facts which have already existed, and from the importance of the Christian doctrine.

MILLE'NNIAL. *a.* (from *millennium*, Latin.) Pertaining to the millennium.

MILLEPEDÆ. See MILLEPEDES.

MILLEPEDES. (*millepes*, from *mille*, a thousand, and *pes*, a foot; named from their numerous feet.) Millipedæ. Wood-lice. The systematic name of this insect is oniscus armadillo of Linnéus. These insects, though they obtain a place in the pharmacopœias, are very seldom used medicinally in this country; they appear to act as stimulants and slight diuretics, and for this purpose they ought to be administered in a much greater dose than is usually prescribed. The expressed juice, or forty or fifty living millepedes, given in a mild drink, is said to cure very obstinate jaundices. See ONISCUS.

MILLEPORA. MILLEPÆ. In zoology, a genus of the class vermes, order zoophyta. Animal an hydra, or polype; corol mostly branched and covered with cylindrical turbinate pores. Thirty-four species, chiefly inhabitants of the Mediterranean; several found on our own coasts, especially in Cornwall; and a few scattered through the seas of America, India, and Polynesia. The mode of propagation and support is similar to that of the MADREPORES, to which article the reader may revert. The following are chiefly worthy of notice.

1. M. mineacea. Very minute, branching into small lobes, and covered with very small pores. Inhabits the Mediterranean and Indian seas: a beautiful little coral, and the smallest of its genus, being seldom above a quarter of an inch high: the whole surface when magnified appears full of minute, white, blind spiracles, and on the tops of the lobes are several scattered holes surmounted with a margin; the base is broad, and by this it adheres to shells, rocks, and other corals.

2. M. cervicornis. A little compressed, dichotomous, with cells on both sides, and tubular, somewhat prominent florets. Inhabits the Mediterranean and Cornish coasts; from five to six inches high; reddish, or yellowish-brown, within whitish; branched like the horns of a stag, and appearing as if covered with varnish: a few of the pores are divided at the base, narrow, and of brittle texture.

3. M. cellulosa. Membranaceous, reticulate, funnel-form, irregularly waved and plaited at the margin, with numerous pores on one side. Inhabits the Mediterranean and European seas, fixed to marine substances, and resembles a piece of lace, consisting of a flat, erect, undulating membrane, covered with large, regular perforations; sometimes cup-shaped, at other times running into loose folds with a waved margin like a ruffle: about three inches high, solid, brittle, white, or yellowish-grey, with very vivacious polypes.

4. M. polymorpha. Crustaceous, solid, irregularly shaped, but generally branched and tuberculate, and without visible pores. Inhabits most European seas: like the isis, and various other zoophytes, it was formerly employed as an asborbent: and is the common corol of the shops, formed into toys for children: in many places it grows in such abundance that it is burnt for manure; colour red, yellowish, greenish, cinereous, but seldom white; sometimes it is shaped like the kernel of a walnut; often in large compressed masses; at other times, botryoidal; but most frequently found in short, irregular ramifications of a chalky tuberculate appearance, and stony substance.

5. M. violacea. Flat, branching, with erect, flexuous, round ramifications a little compressed, and a porous suture encompassing the margin. Inhabits the South Sea islands; about three inches high; fine violet blue, with two rows of small pores on each side the margin, besides the line of larger ones surrounding it: surface rough, with here and there clusters of little studs.

MILLEPORE, in helminthology. See MILLEPORA.

MI'LLER. *s.* (from *mill.*) One who attends a mill (*Brown*).

MILLER (James), an English dramatic writer, was born in Dorsetshire in 1703. He was designed for trade, but not liking that employment he went to Wadham college, Oxford, and entered into orders. While at the university he wrote a famous comedy, called The Humours of Oxford, performed in 1729. He wrote several other pieces, the last of which was Mahomet, a tragedy; during the run of which the author died in 1743. He also published a volume of sermons, and some poems.

MILLER (Philip), a famous gardener, was born in Scotland in 1691. His father was gardener to the apothecaries' company at Chelsea, to which place Philip succeeded in 1722. He was a fellow of the royal society, and published several works, the greatest of which is his Gardener's Dictionary in folio. He died in 1771.

MILLERIA, in botany, a genus of the class syngenesia, order polygamia penparia. Receptacle naked; downless; calyx one-leafed, two or three parted; florets half radiate. Four species, natives of South America.

MILLER'S THUMB, in ichthyology. See COTTUS.

MILLE'SIMAL. *a.* (*millesimus*, Lat.) Thousandth; consisting of thousandth parts (*Watts*).

MILLET. In botany. See PANICUM.

MILLET-GRASS. See HOLCUS.

MILLETIERE (Theophilus Brachet, sieur de la), a protestant advocate, who turned divine, and wrote a book encouraging the reformed at Rochelle to take up arms in defence of their religion. In 1645 he renounced the protestant religion and embraced popery. He wrote several polemical books, and earnestly recommended a reunion between the catholics and calvinists. He died in 1665, hated by both parties.

MI'LLINER. See MILLENER.

MILLING OF CLOTH. See FULLING and CLOTH.

MILLWORT. See GLAUX.

MI'LLION. *s.* (*million*, French.) 1. The number of a hundred myriads, or ten hundred thousand (*Shakspeare*). 2. A proverbial name for any very great number (*Locke*).

MILLIONTH. *a.* (from *million.*) The ten hundred thousandth (*Bentley*).

MILLOT (Claude Francis Xavier), a French historian, was born at Besançon in 1726, and for some time belonged to the order of jesuits. He was appointed professor of history at Parma, which office he discharged with great reputation for several years. On his return to Paris he became tutor to the duke of Enghein. He died in 1785. He wrote—1. Elemens de l'Histoire de France, depuis Clovis jusqu'à Louis XIV. 3 vols. in 12mo. The author, selecting the most curious and important facts, has suppressed every thing foreign to the subject, and has not only arranged the materials in their proper order, but chosen them with the greatest judgment. Querlon thought this the best abridgment which we have of the history of France, and preferred it to that of the president Henault.—2. Elemens de l'Histoire d'Angleterre, depuis son origine sous les Romains jusqu'à George II. 3 vols. 12mo. A certain critic maintains, that this work is merely a counterfeit of Voltaire's general history. But this censure is altogether unjust. The ancient history in this work is wholly composed by the Abbé Millot; and, no less than the modern part, discovers his abilities in the choice of facts, in divesting them of useless circumstances, in relating them without prejudice, and in adorning them with judicious reflections.—4. Histoire des Troubadours, three vols. 12mo, compiled from the manuscripts of M. de Sainte Palaie. 5. Memoires Politiques et Militaires, pour servir à l'Histoire de Louis XIV, et de Louis XV, 6 vols. 12mo. And various philosophical Discourses.

MILO, a celebrated athlete of Crotona in Italy. It is said that he carried on his shoulders a young bullock four years old, for above forty yards, and afterwards killed it with one blow of his fist, and ate it up in one day. He was seven times crowned at the Pythian games, and six at Olympia. *Ovid. Cic.* &c.—2. T. Annius, a native of Lanuvium, who attempted to obtain the consulship at Rome. Clodius the tribune opposed his views, yet Milo would have succeeded had not an unfortunate rencontre taken place between his suite and that of Clodius as he was going to the country. Clodius and eleven of his servants were killed, and the body of the murdered tribune was carried to Rome and exposed to public view. Cicero undertook the defence of Milo, but with no effect; he was condemned and banished to Massilia.—3. A general of the forces of Pyrrhus. He was made governor of Tarentum, and that he might be reminded of his duty to his sovereign, Pyrrhus sent him as a present a chain, which was covered with the skin of Nicias the physician, who had perfidiously offered the Romans to poison his royal master for a sum of money.

Milo, an island of the Archipelago, about 50 miles in circumference. It has one of the largest and most commodious harbours of the Mediterranean, which serves as a retreat for all vessels that go to, or come from, the Levant. The inhabitants, who are all Greeks, except the cadi, are good sailors. Here are two bishops, one of the Greek, and the other of the Latin church.

Milo, the capital of the above island, is situated on the eastern part of it, and contains about 5000 inhabitants. It is 60 miles N. of Candia. Lat. 36. 41 N. Lon. 25. 6 E.

MILT, in anatomy, a popular name for the spleen. See Anatomy.

Milt, or Melt, in natural history, the soft roe in fishes; thus called from its yielding, by expression, a whitish juice resembling milk. (See Roe.) The milt is properly the seed or spermatic part of the male fish. The milt of a carp is reckoned a choice bit. It consists of two long whitish irregular bodies, each included in a very thin fine membrane. M. Petit considers them as the testicles of the fish wherein the seed is preserved; the lower part, next the anus, he takes for the vesiculæ seminales.

To Milt. *v. a.* (from the noun.) To impregnate the roe or spawn of the female fish.

Milt-waste. See Asplenium.

MILTHORP, a port-town of Westmoreland, at the mouth of the Can, five miles from Kendal. It is the only sea-port in the county; and goods are brought hither in small vessels from Grange in Lancashire. Here are two paper-mills. It has a market on Friday, and a fair on old May-day; and there is a good stone bridge over the river Betha, which runs through the town.

MILTENBURG, a town of Franconia, in Germany, 20 miles S. E. of Aschaffenburg. Lat. 49. 46 N. Lon. 9. 19 E.

MILTIADES. There were two of this name recorded in ancient history, both Athenians; one the son of Cypselus, the other the celebrated captain, the son of Cymon, who made himself absolute in the Chersonesus, whither he was sent by the Athenians, and who in some time after signalized himself so much by the victory at Marathon over the Persian army. (See Marathon.) Some time after this battle Miltiades was entrusted with a fleet of 70 ships, and ordered to punish those islands which had revolted to the Persians. He was successful at first, but a sudden report that the Persian fleet was coming to attack him changed his operations as he was besieging Paros. He raised the siege and returned to Athens, where he was accused of treason, and particularly of holding correspondence with the enemy. A wound which he had received before Paros detained him at home from making his defence, and his enemies taking advantage of his absence, he was condemned to death, but the rigour of the sentence was retracted on the recollection of his great services to the Athenians; he was put into prison till he had paid a fine of 50 talents to the state. His inability detained him in confinement, and soon after his wounds became incurable, and he died about 489 years before the Christian era. His body was ransomed by his son Cimon, who was obliged to borrow and pay the 50 talents, to give his father a decent burial.

MILTON, an ancient town of Dorsetshire, having a market on Tuesdays. This place was famous for its abbey, which is now in ruins. It is 113 miles W. by S. of London.

Milton, a town of Kent, having a market on Saturdays. It is seated on a creek of the river Medway, near the isle of Sheppey, and is much noted for the excellence of its oysters. It is governed by a constable, and is 42 miles E. of London.

Milton (John), the most illustrious of the English poets, was descended of a genteel family, seated at a place of their own name, viz. Milton, in Oxfordshire. He was born December 9, 1608, and received his first rudiments of education under the care of his parents, assisted by a private tutor. He afterwards passed some time at St. Paul's school, London; in which city his father had settled, being engaged in the business of a scrivener. At the age of 17 he was sent to Christ's college, Cambridge, where he made a great progress in all parts of academical learning, but his chief delight was in poetry. In 1628, he proceeded bachelor of arts, having performed his exercise for it with great applause. His father designed him for the church; but the young gentleman's attachment to the muses was so strong, that it became impossible to engage him in any other pursuits. In 1632 he took the degree of master of arts; and having now spent as much time in the university as became a person who determined not to engage in any of the three professions, he left the college, greatly regretted by his acquaintance, but highly displeased with the usual method of training up youth there for the study of divinity; and being much out of humour with the public administration of ecclesiastical affairs, he grew dissatisfied with the established form of church government, and disliked the whole plan of education practised in the university. His parents, who now dwelt at Horton, near Colnbrook, in Buckinghamshire, received him with unabated affection, notwithstanding he had thwarted their views of providing for him in the church; and they amply indulged him in his love of retirement, wherein he enriched his mind with the choicest stores of Grecian and Roman literature: and his poems of Comus, L'Allegro, Il Penseroso, and Lycidas, all written at this time, would have been sufficient, had he never produced any thing more considerable, to have transmitted his fame to latest posterity. However, he was not so absorbed in his studies as not to make frequent excursions to London; neither did so much excellence pass unnoticed among his neighbours in the country, with the most distinguished of whom he sometimes chose to relax his mind, and improve his acquaintance with the world as well as with books.—After five years spent in this manner, he obtained his father's permission to travel for farther improvement. At Paris he became acquainted with the celebrated Hugo Grotius: and from thence travelling into Italy, he was every where caressed by persons of the most eminent quality and learning.

Upon his return home, he set up a genteel academy in Aldersgate-street.—In 1641 he began to draw his pen in defence of the presbyterian party, and the next year he married the daughter of Richard Powell, Esq. of Forest-Hill in Oxfordshire. This lady, however, whether from a difference on account of party, her father being a zealous royalist, or some other cause, soon thought proper to return to her relations; which so incensed her husband, that he resolved never to take her again, and wrote and published several tracts in defence of the doctrine and discipline of divorce. He even made his addresses to another lady; but this incident proved the means of a reconciliation with Mrs. Milton.

In 1644 he wrote his Tract upon Education; and the restraint on the liberty of the press being continued by act of parliament, he wrote boldly and nobly against that restraint. In 1645 he published his juvenile poems; and about two years after, on the death of his father, he took a smaller house in High Holborn, the back of which opened into Lincoln's-Inn-Fields.—Here he quietly prosecuted his studies, till the fatal catastrophe and death of Charles I.; on which occasion he published his Tenure of Kings and Magistrates, in justification of the fact. He was now taken into the service of the commonwealth, and made Latin secretary to the council of state, who resolved neither to write to others abroad, nor to receive any answers, except in the Latin tongue, which was common to them all. The famous Εικων βασιλικη coming out about the same time, our author, by command, wrote and published his Iconoclastes the same year. It was also by order of his masters, backed by the reward of 1000*l.* that in 1651 he published his celebrated piece, entitled Pro Populo Anglicano Defensio." A Defence of the People of England, in answer to Salmatius's Defence of the King;" which performance spread his fame over all Europe.—He now dwelt in a pleasant house, with a garden in Petty France, Westminster, opening into St. James's Park. In 1652 he buried his wife, who died not long after the delivery of her fourth child; and about the same time he also lost his eye-sight, by a gutta serena, which had been growing upon him many years.

Cromwell took the reins of government into his own hands in the year 1653; but Milton still held his office. His leisure hours he employed in prosecuting his studies; wherein he was so far from being discouraged by the loss of his sight, that he even conceived hopes this misfortune would add new vigour to his genius; which, in fact, seems to have been the case. Thus animated, he again ventured upon matrimony: his second lady was the daughter of Captain Woodstock of Hackney; she died in child-bed about a year after. On the deposition of the protector, Richard Cromwell, and on the return of the long parliament, Milton being still continued secretary, he appeared again in print, pleading for a farther reformation of the laws relating to religion; and, during the anarchy that ensued, he drew up several schemes for re-establishing the commonwealth, exerting all his faculties to prevent the return of Charles II. England's destiny, however, and Charles's good fortune, prevailing, our author chose to consult his safety, and retired to a friend's house in Bartholomew-close. A particular prosecution was intended against him; but the just esteem to which his admirable genius and extraordinary accomplishments entitled him had raised him so many friends, even among those of the opposite party, that he was included in the general amnesty.

This storm over, he married a third wife, Elizabeth, daughter of Mr. Minshall, a Cheshire gentleman; and not long after he took a house in the Artillery Walk leading to Bunhill-fields. This was his last stage: here he sat down for a longer continuance than he had been able to do any where; and though he had lost his fortune (for every thing belonging to him went to wreck at the Restoration), he did not lose his taste for literature, but continued his studies with almost as much ardour as ever; and applied himself particularly to the finishing his grand work, the Paradise Lost, one of the noblest poems that ever was produced by human genius. -It was published in 1667, and his Paradise Regained came out in 1670.—This latter work fell short of the excellence of the former production; although, were it not for the transcendent merit of

Paradise Lost, the second composition would doubtless have stood foremost in the rank of English epic poems. After this he published many pieces in prose, for which we refer our readers to the edition of his Historical, Poetical, and Miscellaneous Works, printed by Millar, in 2 vols. 4to, in 1753.

In 1674 this great man paid the last debt to nature at his house in Bunhill-fields, in the 66th year of his age; and was interred on the 12th of November, in the chancel of St. Giles's, Cripplegate. A decent monument was erected to his memory, in 1737, in Westminster abbey, by Mr. Benson, one of the auditors of the imprest. His person was remarkably handsome, but his constitution was tender.

Memoirs of the life of Milton have been ably written by Mr. Hayley, Dr. Symonds, and others: but one of the most interesting sketches of this kind, both as it regards biography and criticism, is that by Dr. Johnson. It displays the great powers, and unfortunately at the same time the great prejudices, of that learned man; yet we wish we had room to select more than two or three of its characteristic passages.

Dryden remarks that Milton has some flats among his elevations. But says Johnson, "this is only to say, that all the parts are not equal. In every work, one part must be for the sake of others; a palace must have passages; a poem must have transitions. It is no more to be required that wit should be always blazing, than that the sun should always stand at noon. In a great work there is a vicissitude of luminous and opaque parts, as there is in the world a succession of day and night. Milton, when he has expatiated in the sky, may be allowed sometimes to revisit earth; for what other author ever soared so high, or sustained his flight so long!"

Once more, "Milton was naturally a thinker for himself, confident of his own abilities, and disdainful of help or hindrance: he did not refuse admission to the thoughts or images of his predecessors, but he did not seek them. From his contemporaries he neither courted nor received support; there is in his writings nothing by which the pride of other authors might be gratified, or favour gained; no exchange of praise, nor solicitations of support. His great works were performed under discountenance, and in his blindness; but difficulties vanished at his touch: he was born for whatever is arduous; and Paradise Lost is not the greatest of heroic poems, only because it is not the first."

Again, "The characteristic quality of his poem is sublimity. He sometimes descends to the elegant, but his element is the great. He can occasionally invest himself with grace, but his natural part is gigantic loftiness. He can please when pleasure is required; but it is his peculiar power to astonish.

"He seems to have been well acquainted with his own genius, and to know what it was that nature had bestowed upon him more bountifully than upon others, the power of displaying the vast, illuminating the splendid, exposing the awful, darkening the gloomy, and aggravating the dreadful: he therefore chose a subject on which too much could not be said, on which he might tire his fancy without the censure of extravagance.

"The appearances of nature, and the occurrences of life, did not satiate his appetite for greatness. To paint things as they are requires a minute attention, and employs the memory rather than the fancy. Milton's delight was to sport in the wide regions of possibility; reality was a scene too narrow for his mind. He sent his faculties out upon discovery, into worlds where only imagination can travel, and delighted to form new modes of existence, and furnish sentiment and action to superior beings, to trace the counsels of hell, or accompany the choirs of heaven."

Lastly, "In Milton every line breathes sanctity of thought, and purity of manners, except when the train of the narration requires the introduction of the rebellious spirits; and even they are compelled to acknowledge their subjection to God, in such a manner as excites reverence, and confirms piety."

MIME. *s.* (μιμος.) A buffoon who practises gesticulations, either representative of some action, or merely contrived to raise mirth (*B. Jonson*).

To MIME. *v. n.* To play the mime (*B. Jon.*).

MI'MER. *s.* (from *mime.*) A mimic (*Milt.*).

MI'MICAL. *a.* (*mimicus*, Latin.) Imitative; befitting a mimic; acting the mimic (*Dryden*).

MI'MIC. *a.* (*mimicus*, Latin.) Imitative (*Swift*).

To MI'MIC. *v. a.* (from the noun.) To imitate as a buffoon; to ridicule by a burlesque imitation (*Granville*).

MI'MICALLY. *ad.* In imitation; in a mimical manner

MIMIC. *s.* (*mimicus*, Latin.) 1. A ludicrous imitator; a buffoon who copies another's act or manner (*Prior*). 2. A mean or servile imitator.

MI'MICRY. *s.* (from *mimic.*) Burlesque imitation (*Spectator*).

MIMNERMUS, a Greek poet and musician of Colophon in the age of Solon. He chiefly excelled in elegiac poetry, whence some have attributed the invention of it to him In the expression of love, Propertius prefers him to Homer, as this verse shews:

Plus in amore valet Mimnermi versus
Homero. Lib. i. Eleg. 9. v. 11.

And Horace bears testimony to his abilities, in describing that seducing passion:

Si Mimnermus uti censet, sine amore jocisque
Nil est jucundum, vivas in amore jocisque.
Epist. vi. lib. i. v. 65.

If, as wise Mimnermus said,
Life unblest with love and joy
Ranks us with the senseless dead,
Let these gifts each hour employ.

Alluding to some much-admired lines of this

Greek poet, which have been preserved by Stobæus.

Τις δε βιος, τι δε τερπνον, ατερ χρυσης Αφροδιτης, &c.

What is life and all its pride,
If love and pleasure be denied?
Snatch, snatch me hence, ye fates, whene'er
The am'rous bliss I cease to share.
Oh let us crop each fragrant flow'r
While youth and vigour give us pow'r:
For frozen age will soon destroy
The force to give or take a joy;
And then, a prey to pain and care,
Detested by the young and fair,
The sun's blest beams will hateful grow,
And only shine on scenes of woe.

MIMO'GRAPHER. *s.* (*mimus* and γϱάφω.) A writer of farces.

MIMO'SA. Sensitive plant. In botany, a genus of the class polygamia, order monœcia. Calyx five-toothed; corol five-cleft; stamens five or more; style one; stigma truncate; legume various. Eighty-five species, scattered over the warm climates of the globe. They may be thus subdivided:

A. Leaves simple.
B. Leaves simply-pinnate.
C. Leaves bigemminate, or tergeminate.
D. Leaves conjugate, and also pinnate.
E. Leaves doubly-pinnate. This subdivision embraces more than half the genus. The following are the chief species.

1. M. sensitiva. Common sensitive plant. Prickly: partial leaflets two-pair; the innermost very small: flowers purple, in roundish heads, succeeded by broad, flat jointed pods, in radiated clusters. The leaves and foot-stalks recede from the touch. A native of Brazil.

2. M. pudica. Bashful sensitive plant. Prickly: leaves somewhat digitate; stem bristly. Peculiarly sensitive to the approach of the hand, both in stalk and leaves. A native of Brazil.

3. M. viva. Lively mimosa. Unarmed; partial leaflets four pair, roundish; stem herbaceous, unarmed. A native of Jamaica; retaining the letters or name of a person for several minutes after such letters have been run over the leaves with a stick.

4. M. scandens. Cacoons, or Mafotoo wyth. Unarmed; leaves ending in a tendril; leaflets two pair. A native of both the Indies: its pod is eight or nine feet long, the largest and longast in botany, containing from ten to fifteen seeds.

5. M. catechu. Spines stipular; leaves many pair; glands of the partial ones solitary; spikes filiform, axillary, in pairs or threes, peduncled. A native of Hindustan, from which the drug called terra japonica is obtained by a decoction of the wood. See TERRA JAPONICA and CATECHU.

6. M. nilotica. Spines stipular, spreading; outer partial leaves separated by a gland; spikes globular, peduncled. A native tree of Arabia; about fifteen feet high, with a lupin-like pod, containing flattish brown seeds. From the branches and stem exudes the gum Arabic of the shops. See the article ARABICUM GUMMI.

7. M. Senegal. Spines in threes, the middle one reflected; flowers in spikes. A native of Arabia and Africa. The gum Senegal exudes from it; which has a close resemblance to gum Arabic. See the article GUMMI SENEGALENSE.

The three last species are strictly acacias: the nilotic mimosa is the true acacia or Egyptian thorn. But this genus in the Linnéan system comprehends as well the acacia and inga tribes, as the mimosas of other authors, all of which are too numerous to be particularly detailed.

The manner of propagating acacias is to sow their seeds in a hot-bed in spring; they will soon appear above the ground, and are then to be transplanted. For this purpose, another hot-bed must be prepared, into which must be plunged as many small pots as there is occasion for. These must be first filled with earth; and when they have stood twenty-four hours, this earth will be of a proper warmth. Then the plants are to be raised gently out of the first hot-bed, and planted one in the middle of each pot, and watered gently to settle the earth to their roots. The bed is then to be shaded with mats till they have taken root; and after this air must be given them, as they are able to bear it, by raising the glasses which cover the beds. There are two kinds, called the locust tree and the water acacia of Carolina, which, with the other hardier kinds, may be wholly uncovered in the hot-bed by midsummer. The first and second winter, these should be sheltered in a common hot-bed frame, till they are grown woody; and after this, they may be taken out of the pots in the spring of the year, and planted in the open ground, where they are intended to stand; which should always be in a wilderness or clump of trees, where they may be sheltered from the wind, the violence of which is otherwise apt to split them. When they are eight or ten feet high, they will make very vigorous shoots, which should be annually shortened, that the heads of the trees may not become open and naked. They love a loose and somewhat moist soil.

The other and tender kinds of acacia should be kept in the hot-beds till July, and after this be exposed to the air by degrees, though the glasses should not be removed from them wholly for the first year. These must be set in a stove the first and second winters; but when they are grown woody, they will live in a good green-house, and may be exposed in summer, as myrtles, orange-trees, and the like. They must be very little watered in winter; especially those which shed their leaves. The tenderest kinds of all, which are the true Egyptian acacia, the branched-leafed acacia, with twisted pods, and the large four-leaved acacia with twisted pods, must have a hot-bed of tanner's bark, and be shifted into larger pots, as they increase in bulk. The earth for these must be somewhat sandy; and great care must be taken not to give them too large pots. The first of these three may, when grown woody, be set in a common stove, among viburnums, and similar plants; but the other two must have a bark-stove in winter: nor should they be exposed to the open air in summer, at least till they are four or five years old. In winter, these are to have very little water; but in summer they require frequent refreshings.

The inga may be propagated by seeds, in the manner directed for the acacia, only that the plants being too tender to endure the open air of this country, must not be removed out of the stove, even in the warmest part of the year; but they are only preserved in curious gardens, for the sake of variety. The sensitive plant, or the mimosa, strictly so called, may be propagated by seeds in the same manner with the inga, and other natives of warm climates.

The sensitive plant is so denominated, from its remarkable property of receding from the touch, and giving signs, as it were, of animal life and sensation; this motion it performs by means of three distinct articulations, viz. of a single leaf with its pedicle, of the pedicle to its branch, and of the branch to the trunk, or main stem; the primary motion of all which is the closing of the two halves of the leaf on its rib; then the rib or pedicle itself closes; and if the motion with which the plant is moved be very strong, the very branches have the sensation propagated to them, and apply themselves to the main stem, as the simple leaves did before to their ribs, and these ribs to their branches; so that the whole plant, in this state, forms itself, from a very complexly branched figure, into a sort of straight, cylindrical one.

MIMULUS. Monkey-flower. In botany, a genus of the class didynamia, order angiospermia. Calyx five-toothed, prismatic; the upper lip folded back at the sides; capsule two-celled; many seeded. Four species: natives of North or South America, with blue or yellow flowers.

MIMUSOP. In botany, a genus of the class octandria, order digynia. Calyx five-leaved; corolless: capsule one-celled; three-valved; seeds a few. Three species: herbs of Spain.

MINA, or MANEH, a species of money, which properly signifies one part or ounce. It is observed that this word occurs only in the books of Kings, Chronicles, Ezra, and Ezekiel. This prophet (xlv. 12.) tells us, that the minah or maneh was valued at 60 shekels, which in gold make of our English money about 54¾ pounds, and in silver almost seven pounds. Thus for the Hebrew maneh. But the Greek or Attic mina, which is probably that mentioned in the books of the Maccabees and in the New Testament, is valued at 100 drachmæ, or about 2*l*. 17*s*. sterling. There was also a lesser mina, which was valued at 75 drachmæ.

MINA'CIOUS. *a.* (*minax.* Lat.) Full of threats.

MINA'CITY. *s.* (*from minax,* Lat.) Disposition to use threats.

MINAGNGHINIM, a pulsatile instrument of music, among the Hebrews, which was a square table of wood fitted with a handle; over this table was stretched an iron chain, or hempen cord, passing through balls of wood or brass, which struck against the table when the instrument was shook, and occasioned a clear sound, which might be heard at a great distance.

MI'NATORY. *a.* (*minor,* Latin.) Threatening (*Bacon*).

To MINCE. *v. a.* (from *minish.*) 1. To cut into small parts (*South*). 2. To mention any thing scrupulously, by a little at a time; to palliate (*Woodward*). 3. To speak with affected softness; to clip the words (*Shakspeare*).

To MINCE. *v. n.* 1. To walk nicely by short steps (*Pope*). 2. To speak small and imperfectly (*Dryden*).

MINCHA, in the Jewish customs, offerings of meal, cakes, or biscuits, made in the temple of the Lord. The Seventy have sometimes preserved this word in their translation; but instead of *mincha* they read *manaa*, which doubtless was the received pronunciation in their time.

MINCHING HAMPTON, a town of Gloucestershire, 20 miles from Bath and Bristol, and near 90 from London, with a market on Tuesdays, and two fairs. The parish is pretty large, being bounded on the north by the Stroud, and on the south by the brook Avening; and has 12 hamlets belonging to it, with a common called Amberley. Here is a good large rectory church, built in form of a cross, and worth 200l. a-year. Near it are very large camps, with deep trenches; and near Dunkirk in this parish are fulling-mills.

MI'NCINGLY. *ad.* (from *mince.*) In small parts; not fully (*Hooker*).

MINCIUS, a river of the Transpadana; running from, or rather transmitted through, the Lacus Benacus, from north to south, into the Padus; but originally rising in the Rhetian Alps. Now Mincio or Menzo, running through the duchy of Mantua into the Po.

MIND. *s.* (ᵹeminꝺ, Saxon.) 1. The intelligent power (*Shakspeare*). 2. Intellectual capacity (*Cowley*). 3. Liking; choice; inclination; propension; affection (*Hooker*). 4. Thoughts; sentiments (*Dryden*). 5. Opinion (*Granville*). 6. Memory; remembrance.

To MIND. *v. a.* (from the noun.) 1. To mark; to attend (*Roscommon*). 2. To put in mind; to remind (*Burnet*).

To MIND. *v. n.* To incline; to be disposed (*Spenser*).

MINDANAO, the largest of the Philippine Islands, in Asia, except Manilla. It is almost the only one that is not subject to Spain; its length being about 200 miles, and its breadth 150. The inhabitants are of a very different description from those of the other Philippine Islands. Those of the inland country are supposed to be the ancient pagan inhabitants, whom the Mahometans, that possess the coasts, have driven up to the mountains. The air of

Mindanao is not excessively hot, though it lies within six degrees of the equator, as it is refreshed by the sea-breezes on every side in the day-time. The middle of the country is woody and mountainous: but between the hills are rich valleys, and near the sea-coast the country is generally flat. It produces rice, and such fruits as grow between the tropics. They have also libby or sago trees; of the pith of which they make bread. Great quantities of it are exported, after it is dried and drained like seed. The plantain wood is beautiful here, and in great perfection. It is their principal food, and they also make their drink of it. In the reign of Philip II. king of Spain, Don Lewis de Velasco, viceroy of Mexico, sent Michael Lopez de la Gaspes, with a fleet and force sufficient to make a conquest of these islands, which he afterwards named the Philippines, in honour of the above monarch.

The city of Magindanao is situated on the south-east side of the island, has a river capable of admitting small vessels, and carries on a considerable trade with Manilla, Sooloo, Borneo, and the Moluccas. Their exports are rice, tobacco, bees-wax, and spices; in return for which they receive coarse cloths of Coromandel, China-ware, and opium. The village or town of Samboingan is situated on the banks of a small rivulet, which empties itself immediately into the sea, and is agreeably shaded by groves of cocoa trees. The number of its inhabitants are about 1000, among which are included the officers, soldiers, and their respective families. In its environs there are several small lookout houses, erected on posts of twelve feet high, in all of which a constant guard is kept; so that it appears as if the Spaniards were in a continual state of enmity with the natives. The houses are built of those simple materials which are of very general use in the eastern seas. They are erected on posts, and built of bamboo, covered with mats; the lower apartments serve for their hogs, cattle, and poultry, and the upper ones are occupied by the family. Lon. 125. 0 W. Lat. 6. 0 N.

MI'NDED. *a.* (from *mind.*) Disposed; inclined; affected (*Tillotson*).

MINDELHEIM, a town of Suabia, with a castle. It is the capital of a small territory between the rivers Iller and Lech, subject to the house of Bavaria. It was taken by the Austrians, after the battle of Blenheim, who erected it into a principality in favour of the duke of Marlborough; but it returned to the house of Bavaria, by the treaty of Rastadt. It is 30 miles S.E. of Ulm. Lon 10. 42 E. Lat. 48. 3. N.

MINDEN, a town of Westphalia, capital of a territory of the same name. Near this town prince Ferdinand of Brunswick defeated the French in 1759. It is subject to the king of Prussia, and is seated on the Weser; 27 miles E. by S. of Osnaburg, and 37 W. of Hanover. Lon. 9. 5 E. Lat. 52. 22 N.

MI'NDFUL. *a.* (*mind* and *full.*) Attentive; heedful; having memory (*Hammond*).

MI'NDFULLY. *ad.* Attentively; heedfully.

MI'NDFULNESS. *s.* Attention; regard.

MI'NDLESS. *a.* (from *mind.*) 1. Inattentive; regardless (*Prior*). 2. Not endued with a mind; having no intellectual powers (*Davies*). 3. Stupid; unthinking (*Shakspeare*).

MIND-STRICKEN. *a.* (*mind* and *stricken*). Moved; affected in his mind (*Sidney*).

MINDORO, one of the Philippine Islands, 50 miles in circumference, separated from Luconia by a narrow channel. It is full of mountains, which abound in palm-trees, and all sorts of fruit. The inhabitants are pagans, and pay tribute to the Spaniards.

MINE, in natural history, a deep pit under ground, from whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where stones only are procured, the appellation of quarries is universally bestowed upon the places from which they are dug out, however deep they may be.

As, therefore, the matter dug out of mines is various, the mines themselves acquire various denominations, as gold-mines, silver-mines, copper-mines, iron-mines, diamond-mines, salt-mines, mines of antimony, of alum, &c.

Mines, then, in general, are veins or cavities within the earth, whose sides receding from, or approaching nearer to each other, make them of unequal breadths in different places, sometimes forming larger spaces, which are called hules: they are filled with substances, which, whether metallic or of any other nature, are called the loads; when the substances forming these loads are reducible to metal, the loads are by the miners said to be alive; otherwise they are called dead loads. In Cornwall and Devon, the loads always hold their course from eastward to westward; though in other parts of England, they frequently run from north to south. The miners report, that the sides of the load never bear in a perpendicular, but constantly underlay, either to the north or to the south. The load is frequently intercepted by the crossing of a vein of earth, or stone, or some different metallic substance; in which case it generally happens that part of the load is moved a considerable distance to the one side. This transient load is by the miners called flooking: and the part of the load which is to be moved is said to be heaved. According to Dr. Nichols's observations upon mines, they seem to be, or to have been, the channels through which the water pass within the earth, and, like rivers, have their small branches opening into them, in all directions. Most mines have streams of water running through them; and when they are found dry, it seems to be owing to the waters having changed their course, as being obliged to it, either because the load has stopped up the ancient passages, or that some new and more easy ones are made. Mines, says Dr. Shaw, are liable to many contingencies; being sometimes poor, sometimes soon exhaustible, sometimes subject to be drowned, especially when deep, and sometimes hard to trace; yet there are many instances of mines proving highly advantageous for hundreds of years: the mines of Potosi are to this day worked with nearly the same success as at first; the gold-mines of Cremnitz have been worked for thousands of years; and our Cornish tin-mines are extremely ancient. The neat profit of the silver alone, dug in the Misnian silver-mines in Saxony, is still, in the space of eight years, computed at a thousand six hundred and forty-four millions, besides seventy-three tons of gold. Many mines have been discovered by accident: a torrent first laid open a rich vein of the silver-mine at Friberg in Germany; sometimes a violent wind, by blowing up trees, or overturning the parts of rocks, has discovered a mine; the same has happened by violent showers, earthquakes, thunder, the firing of woods, or even the stroke of a plough-share, or horse's hoof.

But the art of mining does not wait for these favourable accidents, but directly goes upon the search and discovery of such mineral veins, ores, or sands, as may be worth the working for metal. The principal investigation and discovery of mines depend upon a particular sagacity, or acquired habit of judging from particular signs, that metallic matters are contained in certain parts of the earth, not far below its surface. The principal signs of a latent metallic vein, seems reducible to general heads, such as, 1. The discovery of certain mineral waters. 2. The discoloration of the trees or grass of a place. 3. The finding of pieces of ore on the surface of the ground. 4. The rise of warm exhalations. 5. The finding of metallic sands, and the like. All which are so many encouragements for making a stricter search near the places where any thing of this kind appears; whence rules of practice might be formed for reducing this art to a greater certainty. But when no evident mark of a mine appears, the skilful mineralist usually bores into the earth, in such places as from some analogy of knowledge, gained by experience, or by observing the situation, course, or nature of other mines, he judges may contain metal.

After the mine is found, the next thing to be considered is whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like, and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

Particularly the form and situation of the spot should be well considered. A mine must either happen, 1. In a mountain. 2. In a hill. 3. In a valley. Or, 4. in a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water and to form gangways for bringing out the lead, &c. In all the four cases we are to look out for the veins which the rains, or other accidental thing, may have laid bare; and if such a vein be found, it may often be proper to open the mine at that place, especially if the vein prove tolerably large and rich: otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat, nor on the tops of mountains, but on the sides. The best situation for a mine is a mountainous, woody, wholesome spot; of a safe easy ascent, and bordering on a navigable river. The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places, where mines are found, prove poisonous, and can upon no account be dug, though ever so rich: the way of examining a suspected place of this kind, is to make experiments upon brutes, by exposing them to the effluvia or exhalations to find the effect. (*British Ency.*)

Mine, in military affairs, is also a subterraneous cavity made according to the rules of art, in which a certain quantity of powder is lodged, which by its explosion blows up the earth above it.

It has been found by experiment that the figure produced by the explosion is a paraboloid; and that the centre of the powder, or charge, occupies the focus.

The place where the powder is lodged is called the chamber of the mine, or forneau.

The passage leading to the powder is called the gallery.

The line drawn from the centre of the chamber, perpendicular to the nearest surface of the ground, is called the line of least resistance.

The pit or hole, made by springing the mine, is called the excavation.

The fire is communicated to the mine by a pipe or hose, made of coarse cloth, whose diameter is about one inch and a half, called a saucisson (for the filling of which near half a pound of powder is allowed to every foot), extending from the chamber to the entrance of the gallery; to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber.

To prevent the powder from contracting any dampness, the saucisson is laid in a small trough, called an auget, made of boards, three inches and a half broad, joined together lengthwise, with straw in it, and round the saucisson, with a wooden cover nailed upon it.

Galleries and chambers of mines.—Galleries made within the fortification, before the place is attacked, and from which several branches are carried to different places, are generally four feet or four and a half wide, and five feet or five and a half high. The earth is supported from falling in by arches and walls, if they are to remain for a considerable time; but when mines are made to be used in a short time, then the galleries are but three feet or three and a half wide, and five feet high, and the earth is supported by wooden frames or props.

The gallery being carried on to the place where the powder is to be lodged, the miners make the chamber. This is generally of a cubical form, large enough to hold the wooden box, which contains the powder necessary for the charge: the box is lined with straw and sand-bags, to prevent the powder from contracting dampness.

The chamber is sunk something lower than the gallery, if the soil permits; but where water is to be apprehended, it must be made higher than the gallery; otherwise the besieged will let in the water, and spoil the mine.

Quantities of powder to charge mines.—Before any calculation can be made of the proper charge for a mine, the density and tenacity of the soil in which it is to be made must be ascertained, either by experiment, or otherwise; for in soils of the same density, that which has the greatest tenacity will require the greatest force to separate its parts. The density is determined by weighing a cubic foot (or any certain quantity) of the soil; but the tenacity can only be determined by making a mine. The following table contains experiments in six different soils, which may be of some assistance to form a judgment of the nature of the soil, when an actual experiment cannot be had:

Nature of the soil.	Density.	Tenacity.
	Weight of one cubic foot.	Quantity of powder to raise one cubic fathom.
1. Loose earth or sand	95 pds.	8 pds.
2. Common light soil	124	10
3. Loam, or strong soil	127	12¼
4. Potter's clay, or stiff soil	135	13½
5. Clay, mixed with stones	160	16
6. Masonry	205	21½

Loading and stopping of mines.—The gallery and chamber being ready to be loaded, a strong box of wood is made of the size and figure of the chamber, being about one-third or one-fourth bigger than is required for containing the necessary quantity of powder: against the sides and bottom of the box is put some straw; and this straw is covered over with empty sand-bags, to prevent the powder from contracting any dampness: a hole is made in the side next the gallery, near the bottom, for the saucisson to pass through; which is fixed to the middle of the bottom, by means of a wooden peg, to prevent its loosening from the powder; or that, if the enemy should get to the entrance, he may not be able to tear it out. This done, the powder is brought in sand-bags, and thrown loose in the box, and covered also with straw and sand-bags; upon this is put the cover of the box, pressed down very tight with strong props; and, to render them more secure, planks are also put above them, against the earth, and wedged in as fast as possible.

This done, the vacant spaces between the props are filled up with stones and dung, and rammed in the strongest manner: the least neglect in this work will considerably alter the effect of the mine.

The auget is then laid from the chamber to the entrance of the gallery, with some straw at the bottom; and the saucisson laid in it, with straw over it: lastly, it must be shut with a wooden cover nailed upon it. Great care must be taken, in stopping up the gallery, not to press too hard upon the auget, for fear of spoiling the saucisson; which may hinder the powder from taking fire, and so prevent the mine from springing. The gallery is stopped up with stones, earth, and dung, well rammed, six or seven feet further from the chamber than the length of the line of least resistance.

Mine. *pronoun possessive.* (mẏn, Saxon.) Belonging to me (*Dryden*).

To Mine. *v. n.* (from the noun.) To dig mines or burrows (*Woodward*).

To Mine. *v. a.* To sap; to ruin by mines; to destroy by slow degrees (*Shakspeare*).

MINEHEAD, a borough in Somersetshire, with a market on Wednesday. It has a good harbour on the Bristol channel, for ships of large burden; and carries on a trade in wool, coal, and herrings. It sends two members to parliament, and is 31 miles N. of Exeter, and 161 W. by S. of London. Lon. 3. 34 W. Lat. 51. 12 N.

MINEIDES, the daughters of Minyas or Mineus, king of Orchomenos, in Bœotia. They were three in number, Leuconoe, Leucippe, and Alcithoe. Ovid calls the two first Clymene and Iris. They derided the orgies of Bacchus, for which impiety the god inspired them with an unconquerable desire of eating human flesh. They drew lots which of them should give up her son as food to the rest. The lot fell upon Leucippe, and she gave up her son Hippasus, who was instantly devoured by the three sisters. They were changed into bats.

MI'NER. *s.* (*mineur*, French.) 1. One who digs for metals (*Dryden*). 2. One who makes military mines (*Tatler*).

MINERAL, in natural history, is used in general for all fossile bodies, whether simple or compound, dug out of a mine; from whence it takes its denomination.

Mineral caoutchouc: a species of Bitumen, which see.

Mineral mummy. Mineral pitch. A species of Bitumen, which see.

Mineral tallow: a species of Bitumen, which see.

Mineral tar: a species of Bitumen, which see.

Mineral waters, (*Aquæ minerales. Aquæ medicinales.*) Waters holding minerals in solution. But as all water, in a natural state, is impregnated, either more or less, with some mineral substances, the name mineral waters should be confined to such waters as are sufficiently impregnated with mineral matters to produce some sensible effects on the animal economy, and either to cure or prevent some of the diseases to which the human body is liable. On this account, these waters might be with much more propriety called medicinal waters, were not the name by which they are commonly known too firmly established by long use.

The first knowledge of mineral waters, like every other branch of knowledge we possess, was accidentally discovered. The good effects they produced on such as used them, have doubtless been the cause of distinguishing them from common waters. The first philosophers who considered their properties attended only to their sensible qualities, such as colour, weight, or lightness, smell, and taste. Pliny, however, distinguished a great number of waters, either by their physical properties or their uses; but the inquiry after methods of ascertaining, by chymical processes, the quantity and quality of the principles held in solution by mineral waters, was not attempted till the seventeenth century. Boyle is one of the first who, in the valuable experiments on colours published by him at Oxford in 1663, mentioned several re-agents capable of indicating the substances dissolved in water, by the alteration produced in their colours. The academy of sciences, from its first institution, was aware of the importance of analysing mineral waters; and Duclos, in 1667, attempted the examination of the mineral waters of France: the researches of this chemist may be found in the original memoirs of this society. Boyle was particularly employed in enquiries respecting mineral waters about the end of the seventeenth century, and published a treatise on this subject in 1685. Boulduc, in the year 1729, published a method of analysing waters, which is much more perfect than any which were employed before his time: it consists in evaporating these fluids at different times, and separating by filtration the substances which are deposited, in proportion as the evaporation proceeds.

Many celebrated chemists have since made successful experiments on mineral waters, and almost every one made valuable discoveries respecting the different principles contained in these fluids. Boulduc discovered natron, and determined its properties: Le Roi, physician of Montpellier, discovered calcareous; muriat Margraaff, the muriat of magnesia; Priestley, carbonic acid; and Monnet and Bergman the sulphurated or hepatic hydrogen gass. The two last-mentioned chemists, besides the discoveries with which they have enriched the art of analysing waters, have published complete treatises on the method of proceeding in this analysis; and have carried this part of chemistry to a degree of perfection and accuracy far exceeding that which it possessed before the time of their labours. We are likewise in possession of particular analyses, made by very good chemists, of a great number of mineral waters, and which serve to throw great light on this inquiry, which, with justice, is esteemed one of the most difficult in the whole art of chemistry. The limits here prescribed do not permit us to enter at large into the history of the analysis of waters, which may be found in many treatises, one of the best of which is that published a few years since by Dr. Saunders.

Principles contained in Mineral Waters.—It is but a few years since the substances capable of remaining in solution in water have been accurately known. This appears to have arisen from the want of accurate chemical methods of ascertaining the nature of these substances: and the certainty of their existence has naturally followed the discovery of methods of ascertaining them. Another cause which has retarded the progress of science in this respect is, that mineral matters dissolved in waters are almost always in very small doses, and are also mixed together in considerable numbers, so that they mutually tend to conceal or alter those properties in which their distinctive characters consist. Nevertheless, the numerous experiments of the chemists before quoted, and a great number of others, which we shall occasionally mention, have shown, that some mineral substances are often found in waters, others scarcely ever met with; and lastly, many which are never held in solution by that fluid. We shall here consider each class of these substances in order.

Siliceous earth is sometimes suspended in waters; and as it is in a state of extreme division, it remains suspended without precipitating; but its quantity is extremely minute. The carbonated alkalis and chalk probably contribute to render siliceous earth soluble.

Alumine likewise appears to exist in water. The extreme subtlety of this earth, by which it is dispersed through the whole mass of water, causes it to render them turbid. Argillaceous waters are therefore whitish, and have a pearl or opal colour; they are likewise smooth, or greasy to the touch, and have been called saponaceous waters. Carbonic acid seems favourable to the suspension and solution of alumine in water.

Lime, magnesia, and barytes, are never found pure in waters; they are always combined with acids.

Fixed alkalis are never met with in a state of purity in waters, but frequently combined with acids, in the form of neutral salts.

The same observation applies to ammoniac, and most acids, except the carbonic acid, which is often free, and in possession of all its properties in waters. It constitutes a peculiar class of mineral waters, known by the name of gaseous, spirituous, or acidulous waters.

Among the neutral salts, with bases of fixed alkalis, scarcely any are met with but sulphat of soda or Glauber's salt, the muriats of soda and of potash, and carbonat of soda, which are frequently dissolved in mineral waters; nitrat and carbonat of potash are rarely found.

Sulphat of lime, calcareous muriat, chalk, sulphat of magnesia, or Epsom salt, muriat of magnesia, and carbonat of magnesia, are the earthy salts which are most commonly found in waters. As to the calcareous nitrat of magnesia, which some chemists have asserted they have met with, these salts are scarcely ever found in mineral waters properly so called, though they exist in salt waters.

The aluminous neutral salts, and salts with base of barytes, are scarcely ever dissolved in waters. Alum or acid sulphat of alumine appears to exist in some waters.

Pure hydrogen gass has not yet been found dissolved in mineral waters.

Pure sulphur has not yet been found in these fluids, though it exists very rarely in small quantities in the state of sulphuret of soda. Sulphureous waters are most commonly mineralized by sulphurated hydrogen gass.

Lastly, Among metals, iron is most commonly dissolved in water, and may be found in two states; either combined with carbonic acid, or with the sulphuric acid. Some chemists have supposed that it was likewise dissolved in its metallic state, without an acid intermedium: but as this metal scarcely ever exists in nature without being in the state of oxyd, combined with the carbonic or sulphuric acid, the opinion of these philosophers could only be maintained at the time when the carbonic acid was not yet discovered: and the solution of iron in water, without the assistance of the sulphuric acid, could not otherwise be accounted for. Bergman affirms, that iron, as well as manganese, is found in certain waters, combined with the muriatic acid.

Oxyd of arsenic, and the sulphats of copper and zinc, which exist in many waters, communicate poisonous properties to them, and show, when discovered by analysis, that the use of such waters must be carefully avoided.

Most chemists at present deny the existence of bitumen in waters: in fact, the bitter taste was the cause why waters were formerly supposed to contain this oily substance; but it is now known that this taste, which does not exist in bitumen, is produced by the calcareous muriat.

There is no difficulty in conceiving how water, which percolates through the interior parts of the globe, and especially through the mountains, may become charged with the different substances we have enumerated. It is likewise clear, that according to the nature and extent of the strata of earth, through which they pass, mineral waters will be more or less charged with these principles, and that the quantity and nature of these principles must be subject to great variations, especially when we consider the changes in the direction of their course to which these fluids are liable from the various alterations which the globe undergoes, particularly on its surface and its more elevated parts.

Classes of Mineral Waters.—It appears from what we have already observed respecting the different substances usually contained in mineral waters, that these fluids may be classed according to the earthy, saline, and metallic substances they hold in solution; and that the number of classes, on this principle, would be very considerable: but it must be observed, that none of these substances are found single and alone in waters; but, on the contrary, they are often dissolved in the number of three, four, five, or even more. This circumstance creates a difficulty in the methodical classification of waters, relative to the principles that they contain. However, if we attend to those substances which are the most abundantly contained in waters, or whose properties are the most prevalent, we shall be able to make a distinction, which, though not very accurate, will be sufficient to arrange these fluids, and to form a judgment of their virtues. Chemists who have attended to mineral waters in general have availed themselves of this method. Monnet has established three classes of mineral waters; the alkaline, the sulphureous, and the ferruginous; and subsequent discoveries have enlarged the number of classes. Duchanoy, who has published a valuable treatise on the art of imitating mineral waters, distinguishes ten, viz. the gaseous, the alkaline, the earthy, the ferruginous, the simple hot, the gaseous thermal, the saponaceous, the sulphureous, the bituminous, and the saline waters. Although it may be urged as a reproach, that this author has made his classes too numerous, since the pure gaseous and bituminous waters are unknown; yet his division is doubtless the most complete, and gives the most accurate idea of the nature of the different mineral waters, and consequently is the best suited to his subject. We shall here propose a division less extensive, and in our opinion more methodical, than that of Duchanoy; at the same time observing, that we do not consider simple thermal waters as mineral waters, because they consist merely of heated water, according to the best chemists; and that we shall not speak of bituminous waters, because none such have been yet found.

It appears to us, that all mineral waters may be arranged in four classes, viz. acidulous, saline, sulphureous, and ferruginous waters.

Class I.—*Acidulous Waters.*

Gaseous waters, which may with more propriety be called acidulous waters, are those in which the carbonic acid predominates; they are known by their sharpe taste, and the facility with which they boil and afford bubbles by simple agitation: they redden the tincture of turnsole, precipitate lime water and alkaline sulphures. As no waters have yet been discovered which contain this acid pure and alone, we think this class may be divided into several orders, according to the other principles contained in them, or the modifications they exhibit. They all appear to contain more or less alkali and calcareous earth; but their different degrees of heat afford a good criterion for dividing them into two orders: the first might comprehend cold, acidulous, and alkaline waters, such as those of Seltzer, Saint-Myon, Bard, Langeac, Chateldon, Vals, &c. in the second might be placed hot, or thermal, acidulous, and alkaline waters, as those of Mount D'Or, Vichy, Chatelguyon, &c.

Class II.—*Saline or Salt Waters.*

By the name of saline waters, we understand such as contain a sufficient quantity of neutral salt to act strongly on the animal economy, so as most commonly to purge. The theory and nature of these waters are easily discovered; they perfectly resemble the solutions of salt made in our laboratories; but they almost always contain two or three different species of salts. The sulphat of soda is very rare; sulphat of magnesia, or Epsom salt, marine salt, or muriat of soda, calcareous and magnesian muriats, or the saline principles which mineralize them, either together or separate. The waters of Sedliz, of Seydschutz, and of Egra, abound with Epsom salt, frequently mixed with muriat of magnesia. Those of Balaruc contain muriat of soda, chalk, and the calcareous and magnesian muriats; those of Bourbonne, muriat of soda, sulphat of lime and chalk; and those of la Mothe contain muriat of soda, sulphat of lime, chalk, sulphat of magnesia, muriat of magnesia, and an extractive matter. It must be here observed, that salts, with base of magnesia, are much more common in waters than has hitherto been supposed; and that few analyses have yet been made in which they have been well distinguished from calcareous muriat.

Class III.—*Sulphureous Waters.*

The name of sulphureous waters has been given to such mineral waters as appear to possess some of the properties of sulphur; such as the smell, and the property of discolouring silver. Chemists have long been ignorant of the true mineralizer of these waters; most have supposed it to be sulphur, but they never succeeded in exhibiting it, or at least have found it in quantities scarcely perceptible. Those who have made experiments on some of these waters have allowed them to contain either sulphureous spirit, or an alkaline sulphur. Venel and Monnet are the first who opposed this opinion; the latter, in particular, nearly discovered the truth, when he considered sulphureous waters as impregnated merely by the vapour of liver of sulphur. Rouelle the younger likewise affirmed, that these fluids might be imitated by agitating water in contact with air, disengaged from an alkaline sulphure by an acid. Bergman carried this doctrine much farther; by examining the properties of sulphurated hydrogen gass, he has proved that this gass mineralizes sulphureous waters, which he therefore calls hepatic waters, and has directed methods of ascertaining the presence of sulphur. Notwithstanding these discoveries, Duchanoy, speaking of sulphureous waters, admits of sulphur, sometimes alkaline, sometimes calcareous, or aluminous. He follows the opinion of Le Roy of Montpellier, who proposed a sulphure with base of magnesia in imitating these waters. It appears in fact to be true, that there are waters which contain a small quantity of sulphur, while there are others which are mineralized only by sulphurated hydrogen gass. In this case it will be necessary to distinguish sulphureous waters into two orders: 1. Those which contain a small quantity of alkaline or calcareous sulphur; and, 2. Those which are only impregnated with sulphuric hydrogen gass. The waters of Bareges and Cauterets, and the Bonnes waters, appear to belong to this first order; and those of St. Amant, Aix la Chapelle, and Montmorency, appear to belong to the second. Most of these waters are thermal, but that of Montmorency is cold.

CLASS IV.—*Ferruginous Waters.*

Iron being the most abundant of metals, and the most susceptible of alteration, it is not to be wondered at that water easily becomes charged with it, and consequently that the ferruginous waters are the most abundant and most common of all mineral waters. Modern chemistry has thrown great light on this class of waters; they were formerly supposed to be all impregnated with sulphat of iron. Monnet has ascertained that most of them do not contain this salt, and he supposed that the iron is dissolved without the intermedium of an acid. It is at present known, that the iron is not in the state of sulphat, but is dissolved by means of the carbonic acid, and forms the salt which we have called the carbonat of iron. Lane, Rouelle, Bergman, and many other chemists, have put this out of doubt. The greater or less quantity of carbonic acid, and the state of the iron in waters of this kind, render it necessary to distinguish the present class into three orders.

The first order comprehends martial acidulous waters, in which the iron is held in solution by the carbonic acid, whose superabundance renders them brisk and subacid. The waters of Bussang, Spa, Pyrmont, Pouhon, and La Dominique de Vals, are of this first order.

The second contains simple martial waters in which the iron is dissolved by the carbonic acid, without excess of the latter. These waters consequently are not acidulous. The water of Forges, Aumale, and Conde, as well as the greater number of ferruginous waters, are of this order; this distinction of ferruginous waters was made by Duchanoy.

But we add a third order, after Monnet, which is that of waters containing sulphat of iron. Though these are extremely rare, yet some of them are found. Monnet has placed the waters of Passy in this order. Opoix admits the sulphat of iron, even in a considerable quantity, in the waters of Provins. It is true, that De Fourcy denies its existence, and considers the iron of these waters as dissolved by carbonic acid. But no decision can be made respecting this subject, because the results of these chemists entirely disagree, and require new experiments to be made. It must be added, that the iron is not found alone in these waters, but is mixed with chalk, sulphat of lime, various muriatic salts, &c. However, as the metal they contain is the principal basis of their properties, they must be called ferruginous, in conformity with the principles we have laid down.

As to the saponaceous waters admitted by Duchanoy, we must wait till chemical and medical experiments have ascertained the cause of their saponaceous property, which this physician attributes to alumine; as well as of the effects they may produce in the animal economy, as medicines, by virtue of this property.

From these details we find, that all mineral and medicinal waters are divided into nine orders, viz.

Cold acidulous waters.
Hot or thermal acidulous waters.
Sulphuric saline waters.
Muriatic saline waters.
Simple sulphureous waters.
Sulphurated gaseous waters.
Simple ferruginous waters.
Ferruginous and acidulous waters.
Sulphuric ferruginous waters.

Examination of Mineral Waters, according to their Physical Properties.—After having shown the different matters which may be found in waters, and exhibited a slight sketch of the method in which they may be divided into classes and orders, according to their principles, it will be necessary to mention the methods of analysing them, and discovering with the greatest possible degree of accuracy the substances they hold in solution. This analysis has been justly considered as the most difficult part of chemistry, since it requires a perfect knowledge of all chemical phenomena, joined to the habit of making experiments. To obtain an accurate knowledge of the nature of any water proposed to be examined, 1. The situation of the spring, and the nature of the soil, more especially with respect to mineral strata, must be carefully observed; for this purpose, cavities may be dug to different depths, in order to discover, by inspection, the substances with which the water may be charged. 2. The physical properties of the water itself, such as its taste, smell, colour, transparence, weight, and temperature, must next be examined; for this purpose, two thermometers, which perfectly agree, and a good hydrometer, must be provided. These preliminary experiments require likewise to be made in the different seasons, different times of the day, and especially in different states of the atmosphere; for a continuance of dry weather, or of abundant rain, has a singular influence on waters. These first trials usually show the class to which the water under examination may be referred, and direct the method of analysis. 3. The depositions formed at the bottom of the basons, the substances which float on the water, and the matters which rise by sublimation, form likewise an object of important research, which must not be neglected. After this preliminary examination, the proper analysis may be proceeded on, which is made after three methods, by re-agents, by distillation, and by evaporation.

Examination of Mineral Waters, by Re-agents.—Those substances, which are mixed with waters, in order to discover the nature of the bodies held in solution by such waters, from the phænomena they present, are called re-agents.

The best chemists have always considered the use of re-agents as a very uncertain method of discovering the principles of mineral waters. This opinion is founded on the considerations that their effects do not determine in an accurate manner the nature of the substances held in solutions in waters; that the cause of the changes which happen in fluids by their addition is often unknown; and that in fact the saline matters usually applied in this analysis are capable of producing a great number of phænomena, respecting which it is often difficult to form any decision. For these reasons, most chemists who have undertaken this analysis have placed little dependence on the application of re-agents. They have concluded, that evaporation affords a much surer method of ascertaining the nature and quantity of the principles of mineral waters: and it is taken for granted, in the best works on the analysis of these fluids, that re-agents are only to be used as secondary means, which at most serve to indicate or afford a probable guess of the nature of the principles contained in waters; and for this reason, modern analysts have admitted no more than a certain number of re-agents, and have greatly diminished the list of those used by the earlier chemists.

But it cannot be doubted at present, that the heat required to evaporate the water, however gentle it may be, must produce sensible alterations in its principles, and change them in such a manner, as that their residues, examined by the different methods of chemistry, shall afford compounds differing from those which were originally held in solution in the water. The loss of the gaseous substances, which frequently are the principal agents in mineral waters, singularly changes their nature, and besides causing a precipitation of many substances, which owe their solubility to the presence of these volatile matters, likewise oduces a re-action among the other fixed matters, whose properties are accordingly changed. The phænomena of double decompositions, which eat is capable of producing between compounds that remain unchanged in cold water, cannot be estimated and allowed for, but in consequence of a long series of experiments not yet made. Without entering, therefore, more fully into these considerations, it will be enough to observe, that this assertion, whose truth is admitted by every chemist, sufficiently shows that evaporation is not entirely to be depended on. Hence it becomes a question, whether there be any method of ascertaining the peculiar nature of substances dissolved in water without having recourse to heat; and whether the accurate results of the numerous experiments of modern writers afford any process for correcting the error which might arise from evaporation. The following pages, extracted from a memoir communicated by M. Fourcroy to the Royal Society of Medicine, will shew, that very pure re-agents used in a peculiar manner may be of much greater use in the analysis of mineral waters than has hitherto been thought.

Among the considerable number of re-agents proposed for the analysis of mineral waters, those which promise the most useful results are tincture of turnsole, syrup of violets, lime-water, pure and caustic potash, caustic ammoniac, concentrated sulphuric acid, nitrous acid, prussiat of lime, gallic alkohol, or spirituous tincture of nutgalls, the nitric solutions of mercury and of silver, paper coloured by the aqueous tincture of fernambouc, which becomes blue by means of alkalis, the aqueous tincture of terra merita, which the same salts convert to a brown red, the oxalic acid to exhibit the smallest quantity of lime, and the muriat of barytes to ascertain the smallest possible quantity of sulphuric acid.

The effects and use of these principal re-agents have been explained by all chemists, but they have not insisted on the necessity of their state of purity. Before they are employed it is of the utmost importance perfectly to ascertain their nature, in order to avoid fallacious effects. Bergman has treated very amply of the alterations they are capable of producing. This celebrated chemist affirms, that paper coloured with the tincture of turnsole becomes of a deeper blue by alkalis; but that it is not altered by the carbonic acid. But as this colouring matter is useful chiefly to ascertain the presence of this acid, he directs its tincture in water to be used, sufficiently diluted, till it has a blue colour. He absolutely rejects syrup of violets, because it is subject to ferment, and because it is scarcely ever obtained without adulteration in Sweden. Morveau adds in a note, that it is easy to distinguish a syrup coloured by turnsole, by the application of corrosive sublimate, which gives it a red colour, while it converts the true syrup of violets to a green.

Lime-water is one of the most useful agents in the analysis of mineral waters, though few chemists have expressly mentioned it in their works. This fluid decomposes metallic salts, especially sulphat of iron, whose metallic oxyd it precipitates; it separates alumine and magnesia from the sulphuric and muriatic acids, to which these substances are frequently united in waters. It likewise indicates the presence of carbonic acid, by its precipitation. M. Gioanetti, a physician of Turin, has very ingeniously applied it to ascertain the quantity of carbonic acid contained in the water of St. Vincent. This chemist, after having observed that the volume or bulk of this acid, from which its quantity has always been estimated, must vary, according to the temperature of the atmosphere, mixed nine parts of lime-water with two parts of the water of St. Vincent: he weighed the calcareous earth formed by the combination of the carbonic acid of the mineral water with lime, and found, according to the calculation of Jaquin, who proves the existence of thirteen ounces of this acid in thirty-two ounces of chalk, that the water of St. Vincent contained somewhat more than fifteen grains. But as the lime-water may seize the carbonic acid united with fixed alkali, as well as that which is at liberty, M. Gioanetti, to ascertain more exactly the quantity of this last, made the same experiment with water deprived of its disengaged acid by ebullition. This process may therefore be employed to determine, in an easy and accurate manner, the weight of disengaged carbonic acid, contained in a gaseous mineral water.

One of the principal reasons which have induced chemists to consider the action of re-agents in the analysis of mineral waters as very fallacious, is, that they are capable of indicating several different substances held in solution in waters, and that it is then very difficult to know exactly the effects they will produce. This observation relates more especially to potash, considered as a re-agent, because it decomposes all the salts which are formed by the union of acids with alumine, magnesia, lime, and metals. When this alkali precipitates a mineral water, it cannot, therefore, be known by simple inspection of the precipitate of what nature the earthy salt decomposed in the experiment may be. Its effect is still more uncertain, when the alkali made use of is saturated with carbonic acid, as is most commonly the case, since the acid to which it is united augments the confusion of effects: for this reason, the use of very pure caustic potash is proposed, which likewise possesses an advantage over the effervescent alkali, viz. that of indicating the presence of chalk dissolved in a gaseous water, by virtue of the superabundant carbonic acid: for it seizes this acid, and the chalk falls down of course. This fact is established by pouring soap lees newly made into an artificial gaseous water, which holds chalk in solution. The latter substance is precipitated in proportion as the caustic fixed alkali seizes the carbonic acid which held it in solution. By evaporating the filtrated water to dryness, carbonat of soda is obtained, strongly effervescent with acids. The caustic fixed alkali likewise occasions a precipitate in mineral waters, though they do not contain earthy salts; for if they contain an alkaline neutral salt, of a less soluble nature, the additional alkali will precipitate it by uniting with the water, nearly in the same manner as alkohol does. M. Gioanetti has observed this phenomenon in the waters of St. Vincent; and it may easily be seen by pouring caustic alkali into a solution of sulphat of potash, or muriat of soda; these two salts being quickly precipitated.

Caustic ammoniac is in general less productive of error when mixed with mineral waters; because it decomposes only salts, with base of alumine or magnesia, and does not precipitate the calcareous salts. It is necessary, however, to make two observations respecting this salt: the first is, that it must be exceedingly caustic, or totally deprived of carbonic acid; without this precaution, it decomposes calcareous salts by double affinity: the second is, that the mixture must not be left exposed to air, when the effect of its action is required to be inspected several hours after it is added; because, as M. Gioanetti has well observed, this salt in a very short time seizes the carbonic acid of the atmosphere, and becomes capable of decomposing calcareous salts. To put this important fact out of doubt, Fourcroy made three decisive experiments; some grains of sulphat of lime, formed of transparent calcareous spar, because chalk, or Spanish white, contain magnesia and river water: he divided this solution into two parts; into the first he poured a few drops of very pure sulphuric acid, recently made, and very caustic; this he put into a well-closed bottle: at the end of twenty-four and forty-eight hours it was clear and transparent, without any precipitate, and therefore no decomposition had taken place. The second portion was treated in the same manner with ammoniac, but placed in a vessel which communicated with the air by a large aperture: at the end of a few hours a cloud was formed near the upper surface, which continually increased, and was at last precipitated to the bottom. This deposition effervesced strongly with sulphuric acid, and formed sulphat of lime. The carbonic acid contained in this precipitate was therefore afforded by the ammoniac which had attracted it from the atmosphere. This combination of carbonic acid and ammoniac forms ammoniacal carbonat, capable of decomposing calcareous salts by double affinity, as Black, Jacquin, and many other chemists have shown, and as may be easily proved by pouring a solution of ammoniacal carbonat into a solution of sulphat of lime, which is not rendered turbid by caustic ammoniac. Lastly, to render the theory of this second experiment clearer, Fourcroy took the first portion to which the caustic ammoniac had been added, and which, having been kept in a close vessel, had lost no part of its transparency. He reversed the bottle which contained it, over the funnel of a very small pneumato-chemical apparatus, and by the assistance of a syphon, passed into it carbonic acid gass, disengaged from the effervescent fixed alkali by sulphuric acid. In proportion as the bubbles of this acid passed through the mixture, it became turbid in the same manner as lime-water; by filtration a precipitate was separated, which was found to be chalk, and the water, by evaporation, afforded ammoniacal sulphat: gaseous water, or the liquid carbonic acid, produced the same composition in another mixture of sulphat of lime, and caustic ammoniac. This decisive experiment clearly shows, that ammoniac decomposes sulphat of lime by double affinity, and by means of the carbonic acid. Hence we see, that when it is required to preserve a mixture of the mineral water with ammoniac for several hours (which is sometimes necessary, because it does not decompose certain earthy salts, but very slowly), the experiment must be made in a vessel which can be accurately closed, in order to prevent the contact of air, which would falsify the result. This precaution, which is of great importance in the use of all re-agents, is likewise mentioned by Bergman and Gioanetti. To these may be added another observation concerning the use of ammoniac. As it is a matter of considerable difficulty to preserve ammoniac in the state of perfect causticity, though it is necessary to be had in such a state, for the analysis of mineral waters, a very simple expedient, which may be applied in this case. It is to pour a small quantity of ammoniac into a retort, whose neck is plunged in the mineral water: when the retort is slightly heated, the ammonical gass becomes disengaged, and passes highly caustic into the water. If it occasions a precipitate, it may be concluded that the mineral water contains sulphat of iron, which may be known by the colour of the precipitate, or otherwise that it contains salts, with base of aluminous or magnesian earth. Generally this precipitate is formed by the chalk which was held in solution in the water, by means of the carbonic acid; ammoniac absorbs this acid, and the chalk is deposited. It is difficult to determine from the physical properties of the earthy precipitate formed in waters by caustic ammoniac, to which of the two last bases it is to be attributed; yet the manner in which it is formed may serve to decide. Six grains of sulphat of magnesia were dissolved in four ounces of distilled water, and six grains of alum in an equal quantity of the same fluid: through each of these solutions a small quantity of ammoniacal gass was passed: the first solution immediately became turbid, while the latter did not begin to exhibit a precipitate till twenty minutes after. These mixtures were carefully included in well-closed bottles. The same phenomenon took place with the nitrats and muriats of magnesia and alumine, dissolved in equal quantities of distilled water, and treated in the same manner. The quickness or slowness of the precipitation of a mineral water, by the addition of ammoniacal gass, therefore affords the means of ascertaining the nature of the earthy salt decomposed by this gass. In general, salts, with base of magnesia, are much more usually met with than those with base of aluminous earth. Bergman has observed, that ammoniac is capable of forming with sulphat of magnesia a compound, in which a portion of this neutral salt is combined, without decomposition, with a portion of ammoniacal sulphat. This non-decomposed portion of sulphat of magnesia may probably form, with the ammoniacal sulphat, a mixed neutral salt, similar to the ammoniaco-mercurial muriat, or sal alembroth. The ammoniac does not, therefore, precipitate the whole of the magnesia, and consequently does not accurately exhibit the quantity of Epsom salt, of which that earth is the base. For this reason lime water is preferable for ascertaining the nature and quantity of salts with base of magnesia contained in mineral waters. It has likewise the property of precipitating the salts with aluminous base much more abundantly and readily than ammoniacal gass.

The concentrated sulphuric acid precipitates a white powder from water which contains barytes, according to Bergman; but, as the same chemist observes, that this earth is seldom found in mineral waters, it will not be necessary to enlarge on the effects of this re-agent. When it produces an effervescence, or bubbles in water, it indicates the presence of chalk, carbonat of soda, or pure carbonic acid; each of these substances may be distinguished by certain peculiar phenomena. If water containing chalk be heated after the addition of sulphuric acid, a pellicle and deposition of sulphat of lime are soon formed, which does not happen with waters which are simply alkaline. At first consideration it may seem that the sulphat of lime ought to be precipitated as soon as the sulphuric acid is poured into water containing chalk; this, however, very seldom happens without the assistance of heat, because these waters most commonly contain a superabundance of carbonic acid, which favours the solution of the sulphat of lime, and of which it is necessary to deprive them before the salt can be precipitated. This fact may be shown in the clearest manner, by pouring a few drops of concentrated sulphuric acid into a certain quantity of lime water which has been precipitated, and afterwards rendered clear by the addition of carbonic acid: if the lime water be highly charged with regenerated calcareous earth, a precipitate of sulphat of lime is thrown down in a few minutes, or more slowly in proportion as the carbonic acid is set at liberty. If no precipitate be afforded by standing, as will be the case when the quantity of sulphat of lime is very small, and the superabundant carbonic acid considerable, the application of a slight degree of heat will cause a pellicle of calcareous sulphat, and a precipitate of the same nature to be formed.

The nitrous acid is recommended by Bergman to precipitate sulphur from hepatized waters. The experiment may be made by pouring a few drops of the brown and fuming acid on distilled water, in which the gas disengaged from caustic alkaline sulphure, heated in a retort, has been received. This artificial hepatic water, which does not considerably differ from natural sulphureous waters, except in the circumstance of its being more difficult to filter, and its always appearing somewhat turbid, affords a precipitate in a few seconds, by the addition of nitrous acid; the precipitate is of a yellowish white; when collected on a filter and dried, it burns with the flame and smell of sulphur, and in other respects has every character of that inflammable body. Nitrous acid seems to alter sulphurated hydrogen gass in the same manner as it does all other inflammable substances, by virtue of the great quantity of oxygen it contains. Scheele has recommended the oxygenated muriatic acid to precipitate the sulphur from waters of this nature: only a very small quantity of it must be used, otherwise the sulphur will be burned and reduced to the state of sulphuric acid. Sulphureous acid precipitates the sulphur very readily from waters which contain it.

There are few re-agents whose mode of action is less known than that of the alkaline lixivium of blood, which has been called phlogisticated alkali; it has been long since ascertained, that this liquor contains Prussian blue, or prussiat of iron, ready formed; it has been thought that this blue might be separated by the addition of an acid; and in this state it has been proposed as a substance capable of exhibiting iron existing in mineral waters. Nothing can be more uncertain than the complete separation of prussiat of iron from this prussiat of potash made of blood. This lixivium ought therefore to be no longer used as a re-agent. Macquer having discovered that Prussian blue is decomposed by alkalis, proposed potash saturated with the colouring matter of this blue, as a test to ascertain the presence of iron in mineral waters. But as the liquor itself likewise contains a small quantity of Prussian blue, which may be separated by means of an acid, as Macquer has shown, Baumé advises that two or three ounces of distilled vinegar be added to each pound of this Prussian alkali, and digested in a gentle heat, till the whole of the Prussian blue is precipitated; after which pure fixed alkali is to be added to saturate the acid of vinegar. Notwithstanding this ingenious process, Fourcroy has observed, that the Prussian alkali, purified by vinegar, deposits Prussian blue in process of time, more especially by evaporation. M. Gioanetti made the same observation by evaporating the Prussian alkali, purified, by the method of Baumé, to dryness: he has proposed two processes for obtaining this liquor in a state of purity, and totally exempt from iron; the one consists in supersaturating the Prussian alkali with distilled vinegar, evaporating it to dryness by a gentle heat, dissolving the remaining mass in distilled water, and filtrating the solution; all the Prussian blue remains on the filter, and the liquor which passes through contains none at all. The other process consists in neutralizing the alkali with a solution of alum, from which after filtrating the sulphat of potash is separated by evaporation. These two liquors do not afford a particle of Prussian blue with the pure acids, nor by evaporation to dryness. The lime water, saturated with the colouring matter of Prussian blue, mentioned by us in treating on iron, does not require these preliminary operations: when poured on a solution of sulphat of iron, it immediately forms pure Prussian blue, without any mixture of green. Acids only precipitate a few particles of Prussian blue from this re-agent; it therefore does not contain iron, and consequently is preferable to the Prussian alkalis, in the assay of mineral waters. This phenomenon doubtless depends on the action of the lime, which, when dissolved in water, is far from having the same efficacy on iron as alkalis have. This prussiat of lime seems to be exceedingly well adapted to distinguish ferruginous waters; whether they be gaseous or sulphuric. In fact the carbonic gass, which holds iron in solution in waters, being of an acid nature, decomposes Prussian lixiviums by the way of double affinity, as well as sulphat of iron. Fourcroy tried prussiat of lime on Spa waters, and those of Passy, and he immediately obtained a very perceptible blue in the former, and very abundant in the latter. This, therefore, is a liquor very easily prepared, which does not contain the smallest portion of Prussian blue, and is exceedingly well calculated to exhibit the presence of small quantities of iron in waters. It is a kind of neutral salt, formed by the prussic acid, or the colouring part of the blue and lime.

Nut-galls, as well as all other bitter and astringent vegetables, such as oak bark, the fruit of the cypress tree, the husks of nuts, &c. have the property of precipitating solutions of iron, and exhibiting that metal of different colours, according to its quantity, its state, and that of the water in which it is dissolved. This colour in general is of all shades, from a pale rose to the deepest black. It is well known that the purple colour assumed by waters, with the tincture of nut-galls, is not a proof that they contain iron in its metallic state, since the sulphat and carbonat of iron likewise assumes a purple colour by the infusion of nut-galls. The differences of colour observed in these precipitations depend rather on the quantity of iron, its greater or less degree of adhesion to the water, and the more or less advanced state of decomposition of the solution, relatively to the quantity of oxygen contained in the iron. The astringent principle is known to be a peculiar acid, since it unites with alkalis, converts blue vegetable colours to a red, decomposes alkaline sulphures, and combines with metallic oxyds. Nut-galls in powder, the infusion of this substance in water, made without heat, and the tincture by alkohol, are used to ascertain the presence of iron in mineral waters. The tincture is preferred, because it is not subject to become mouldy as the aqueous solution is. The distilled products of nut-galls likewise colour ferruginous solutions. The infusions in acids, alkalis, oils, and ether exhibit the same phenomenon. The iron precipitated by this matter from acids is in the state of gallat of iron, and forms a kind of neutral salt, which though very black, is not attracted by the magnet. It dissolves slowly, and without sensible effervescence in acids, but loses these properties by the action of fire, and is then attracted by the magnet. The nut-gall is so efficacious a re-agent, that a single drop of its tincture colours, in the space of five minutes, with a purple tinge, three pints of water, which contains only the twenty-fifth part of a grain of sulphat of iron. All these phenomena proceed from the great facility with which the matter of nut-galls burns, and from its readily absorbing from the iron a portion of the oxygen it contains, passing by this means to the state of a black oxyd, or Ethiops, the smallest quantity of which is very perceptible in transparent liquors.

The two last re-agents we shall propose for the examination of waters, are solutions of silver and of mercury in the nitric acid. These have usually been employed to exhibit the presence of the sulphuric or muriatic acids in mineral waters; but many other substances, which do not contain the smallest portion of those, are likewise precipitated by these solutions. The white and heavy striæ which the nitrat of silver exhibits in water, that contains no more than half a grain of muriat of soda in the pint, ascertains the presence of the muriatic acid with great certainty and facility; but they do not in the same manner indicate the presence of the sulphuric acid, since, according to Bergman's estimate, at least thirty grains of sulphat of soda must exist in the pint of water, in order to produce an immediate sensible effect. To this we may add, that fixed alkali, chalk, and magnesia, precipitate the nitric solution of silver in a much more evident manner, and consequently that the precipitation formed in a mineral water by this solution is insufficient to determine with precision the saline or earthy substances from which it arose.

The solution of mercury by the nitric acid is still more productive of error: it not only indicates the presence of the sulphuric and muriatic acids in waters, but it is likewise precipitated by the earthy and alkaline carbonats, in a yellowish powder, which might be mistaken for an effect of the sulphuric acid. It has been commonly supposed, that the very abundant white precipitate which it forms in water is owing to the presence of a muriatic salt; yet mucilaginous and extractive substances exhibit the same phenomenon, as is now well known to all chemists. Besides these sources of error and uncertainty, dependent on the property which several substances have, of producing similar precipitates with the nitric solution of mercury, there are likewise others which depend on the state of this solution itself, and which it is of the utmost consequence to know, in order to avoid very considerable errors in the analysis of waters. Bergman has mentioned some of the remarkable differences observed in this solution, according to the manner in which it is made, either with or without heat, more particularly with respect to the colour of the precipitates it affords by different intermediums; but he does not say a word concerning the property this solution possesses of being precipitated by distilled water, when it is highly charged with the oxyd of mercury; though Monnet mentions this fact in his treatise on the dissolution of metals. As this subject is of great importance in the analysis of waters, Fourcroy endeavoured by a very minute investigation to arrive at some degree of certainty concerning it, and has succeeded, as shall presently appear, by very simple means. He has made a great number of solutions of mercury, in very pure nitric acid, with different doses of these two substances, with heat and in the cold, and with acids of very different strengths. These experiments have afforded the following results.

1. Solutions made in the cold became charged more or less readily with different quantities of mercury, according to the degree of concentration of the nitric acid; but whatever the quantity of mercury dissolved in the cold by the concentrated acid may be, no part of it will be precipitated by mere water. He dissolved in the cold two drachms and a half of mercury, in two drachms of nitrous acid red and fuming, weighing one ounce four drachms and five grains, in a bottle which contained an ounce of distilled water: the combination took place with the utmost rapidity; very dense nitrous gass escaped, together with aqueous vapours, dissipated by the heat of the mixture, amounting to more than one fourth of the acid. This solution was of a deep green, and very transparent: he poured a few drops into half an ounce of distilled water: some white striæ were formed, which were dissolved by agitation, and afforded no

precipitate, though it was the most saturated solution he could make in the cold, and presented the greatest degree of commotion, effervescence, and red vapours, during the combination of the mercury and acids. As it had deposited crystals, he added two drachms of distilled water, which dissolved the whole without any appearance of precipitation. With much greater safety, therefore, may such solutions as have been made in the cold with common nitric acid, and half their weight of mercury, be used in the analysis of mineral waters, for they will never afford a precipitate by the addition of mere water.

2. The weakest nitric acid strongly heated on mercury will dissolve a larger quantity than the strongest acid in the cold. The solution, which is of a light yellow colour, will appear thick and oily, and will afford by standing an irregular yellowish mass, which may be changed into a beautiful turbith by the addition of boiling water; this solution poured into distilled water forms a very abundant precipitate of a yellow colour, similar to turbith. A solution made in the cold exhibits the same result, if it be strongly heated, so as to disengage a large quantity of nitrous gass. These solutions made with heat ought therefore to be excluded from the analysis of mineral waters, because they are decomposable by distilled water.

3. The two solutions appear to differ from each other in the quantity of oxyde of mercury, which is much greater in that which is precipitated by the water than in that which is not decomposable by that fluid. M. Fourcroy has proved this, by evaporating equal quantities of both these solutions in an apothecary's phial, to reduce them into red precipitate, and he obtained one fourth more of this precipitate from the solution which is decomposed by water than from that which is not rendered turbid. The specific gravity likewise appeared to me to be a good method of ascertaining the relative quantities of oxyd of mercury contained in these different fluids. He compared weights of equal masses of three mercurial nitrous solutions: the one, which was not at all precipitated by distilled water, and was the result of the first mentioned experiment, weighed one ounce, one drachm, and sixty-seven grains, in a bottle which contained exactly an ounce of distilled water. The second solution was made by a very gentle heat, and produced a slight opal colour with distilled water, and scarcely any sensible quantity of precipitate. The same bottle contained one ounce six drachms twenty-four grains. Lastly, a third mercurial solution considerably heated, and which precipitated a true turbith mineral of a dirty yellow, by distilled water, weighed in the same bottle one ounce seven drachms twenty-five grains. A decisive experiment remained to be made to confirm this opinion still more perfectly. If the solution precipitated by water owed this property to a quantity of mercurial oxyd too large with respect to the acid, it would of course lose that property by the addition of acid; this accordingly happened. Aquafortis was poured on a solution which was decomposed by water, and it soon acquired the property of no longer being precipitated, and was absolutely in the same state as that which had been made slowly at first, by the mere heat of the atmosphere. Monnet has mentioned this process, as a means of preventing crystals or mercurial nitrat from becoming converted into oxyd by the contact of the air. It is by a contrary process, and by evaporating a portion of the acid of a good solution, which is not precipitated by water, that it is converted into a solution much more strongly charged with mercurial oxyd, and consequently capable of being decomposed by water; its original property may be restored by the addition of a quantity of acid, equal to that which it lost by evaporation.

Such are the different considerations M. Fourcroy has thought necessary to exhibit, that the effects of re-agents on waters may be better ascertained: but whatever may be the degree of precision to which researches of this nature may be carried; however extensive the knowledge we may have acquried concerning the degrees of purity, and the different states of such substances as are combined with mineral waters, for the purpose of discovering their principles; if it still remains a fact, that each of these re-agents is capable of indicating two or three different substances dissolved in these waters, the result of their action will always be subject to uncertainty. Lime, for example, seizes the carbonic acid, and precipitates salts with the base of alumine, and of magnesia, as well as the metallic salts. Ammoniac produces the same effect. Fixed alkalis, besides the above-mentioned salts, precipitate those with base of lime. The calcareous prussiat, the prussiat of potash, and gallic alkohol, precipitate the sulphat and carbonat of iron. The nitric solutions of silver and of mercury decompose all the sulphuric and muriatic salts, which may be various both in quantity and in kind, in the same water, and are themselves decomposable by alkalis, chalk, and magnesia. Among this great number of complicated effects, how shall we distinguish that which takes place in the water under examination, or by what means shall we ascertain whether it is simple or compounded?

These questions, though very difficult, for the time when the expedients of chemistry were little known, are nevertheless capable of being discussed in the present state of our knowledge. It must first be observed, that the nature of re-agents being much better known at present than it was some years ago, and their re-action on the principles of water better ascertained, it may, therefore, be strongly presumed that their application may be much more advantageously made than has hitherto been supposed; nevertheless, among the great number of excellent chemists who have attended to the analysis of waters, Messrs. Baumé, Bergman, and Gioanetti, are almost the only persons who have been aware of this great advantage. We have been long in the habit of examining mineral waters by re-agents, in very small doses, and often in glasses; the phenomena of the precipitations observed have been noted down, and the experiment carried no further. Baumé advises, in his chemistry, that a considerable quantity of the mineral water under examination should be saturated with fixed alkalis and with acids, that the precipitates be collected, and their nature examined. Bergman apprehended that the quantity of the principles contained in waters might be judged of from the weight of the precipitates obtained in these mixtures. Several other chemists have likewise employed this method, but always with a view to certain particular circumstances; and no one has hitherto proposed to make a connected analysis of mineral waters by this means. To succeed in this analysis, it would be proper to mix several pounds of the mineral water with each re-agent, till the latter ceases to produce any precipitate: the precipitate should then be suffered to subside during the time of twenty-four hours, in a vessel accurately closed; after which the mixture being filtered, and the precipitate dried and weighed, the operator may proceed to examine it by the known methods. In this manner the nature of the substance will be clearly ascertained, on which the re-agent has acted, and the cause of the decomposition may consequently be inferred. A certain order may be followed in these operations, by mixing the waters first with such substances as stand least capable of altering them, and afterwards passing to other substances capable of producing changes more varied and difficult to explain. The following method is that which Fourcroy commonly uses in this kind of analysis. After having examined the taste, the colour, the weight, and all the other physical properties of a mineral water, he pours four pounds of lime water on an equal quantity of the fluid; if no precipitate is made in twenty-four hours, he is sure that the water contains neither disengaged carbonic acid nor alkaline carbonat, nor earthy salts with the base of aluminous earth or magnesia, nor metallic salts. But if a precipitate be formed, he filters the mixture, and examines the chemical properties of the deposited substance; if it has no taste, if it be insoluble in water, or effervesces with acids, or forms an insipid and almost insoluble salt by the addition of sulphuric acid, he concludes that it is chalk, and that the lime water has acted only on the carbonic acid dissolved in the water. If, on the contrary, it is small in quantity, and subsides very slowly; if it do not effervesce, and affords with the sulphuric acid a styptic salt, or a bitter and very soluble salt, it is formed by magnesia or aluminous earth, and often by both.

After the examination by lime water, Fourcroy pours on four other pounds of the same mineral water, a drachm or two of ammoniac perfectly caustic, or causes ammoniacal gass, disengaged by heat from the alkali, to pass into the water. When the water is saturated, it is left at rest in a close vessel for twenty-four hours; if a precipitate be afforded, it can only consist of ferruginous, or magnesian, or aluminous salts, whose nature is examined by the different methods mentioned in the foregoing paragraph. But the action of ammoniacal gass being more fallacious than that of lime water, which produces the same decompositions, it must be observed that this last should only be used as an assistant means, which does not afford results equally accurate with those produced by the former re-agent.

When salts with base of aluminous earth, or magnesia, have been discovered by lime water, or by ammoniacal gass, the caustic fixed alkalis may be used, to distinguish those with base of lime, such as sulphat and muriat of lime. For this purpose Fourcroy precipitates some pounds of the water, which is examined by either of these liquid alkalis, till it no longer produces any turbidness. As this alkali decomposes salts with base of aluminous earth, as well as those composed of lime; if the precipitate resembles in its form, colour, and quantity, that which lime water has afforded, it may be presumed that the water does not contain calcareous salt, and the chemical examinations of the precipitate usually confirms this suspicion: but if the mixture is much more turbid than that made with lime water; if the deposition be much heavier, more abundant, and more readily afforded, the lime is mixed with magnesia or alumine. This is ascertained by treating the precipitate after the different methods before explained. It may easily be concluded, that iron precipitated by re-agents, at the same time as the salino-terrestrial substances, is easily known by its colour and its taste; and that the small quantity of this metal separated in these processes, is not sufficient to affect the results.

It were useless to explain at large the effects of sulphuric acid, nitrous acid, gall-nuts, or of the calcareous and alkaline prussiats, employed as re-agents on mineral waters. The general account of these effects which has already been given may suffice; it need therefore only be noticed, that when they are mixed in large doses with these waters, and the precipitates collected, the nature and quantity of their principles may be more accurately ascertained, as has been done by Messrs. Bergman and Gioanetti. The products which the nitric solutions of silver or mercury afford when mixed with mineral waters deserve particular attention. It is more particularly necessary to operate with large quantities of water, when these re-agents are used, in order to determine the nature of the acids contained in the waters. The analysis of these fluids will be complete when their acids are known, because these are often combined with the bases exhibited by the re-agents before-mentioned. The colour, the form, and the abundance of the precipitates afforded by the nitric solutions of mercury and silver, have hitherto exhibited to chemists the nature of the acids which caused them. A thick and ponderous deposition immediately formed by these solutions, denotes the muriatic acid: if it is small in quantity, white, and crystallized with the nitrat of silver, or yellowish, and yellow and irregular when formed with that of mercury, and if it subside but slowly, it is attributed to the sulphuric acid. But as these two acids are often met with in the same water, and as alkali and chalk likewise decompose the solutions, the results or deductions made from the physical properties of the precipitates must be uncertain. It is therefore necessary to examine them more effectually: for this purpose, solutions of silver or of mercury may be mixed with five or six pounds of the water intended to be analysed. The mixtures being filtered, twenty-four hours after the precipitates must be dried, and treated according to the methods of chemistry. If the precipitate afforded by the nitric solution of mercury be heated in a retort, the portion of metal united with the muriatic acid of the waters will be volatilized into mercurius dulcis, and that which is combined with the sulphuric acid will remain at the bottom of the vessel, and exhibit a reddish colour. These two salts may likewise be distinguished by putting them on a hot coal; the sulphat of mercury, if present, emits a sulphureous acid, and assumes a red colour; the mercurial muriat remains white, and is volatilized without exhibiting any smell of sulphur. These phænomena likewise serve to distinguish the precipitates which may be formed by the alkaline substances contained in water, since the latter do not emit the sulphureous smell, and are not volatile without decomposition.

The precipitates produced by the combination of mineral waters with the nitric solution of silver may be as easily examined as the foregoing. Sulphat of silver being more soluble than the muriat of the same metal, distilled water may be successfully used to separate these salts. Muriat of silver is known by its fixity, its fusibility, and especially in its being less easily decomposed than sulphat of silver. This last, placed on hot coals, emits a sulphureous smell, and leaves an oxyd of silver, which may be fused without addition.

The Examination of the Mineral Waters by Disti *lation.*—Distillation is used in the analysis of waters, to ascertain the gaseous substances they may be united to. These substances are either air, more or less pure, or carbonic acid, or sulphurated hydrogen gass. To ascertain their nature and quantity, some pounds of the mineral water must be poured into a retort, sufficiently large to contain it, without being filled more than half or two-thirds of its capacity; to this vessel a recurved tube is to be adapted, which passes beneath an inverted vessel filled with mercury. In this disposition of the apparatus, the retort must be heated till the water perfectly boils, or till no more elastic fluid passes over. When the operation is finished, the quantity of air contained in the empty space of the retort must be subtracted from the bulk of the gass obtained; the rest consists of aeriform fluid, which was contained in the mineral water, whose properties may quickly be known by the proofs of a lighted taper, tincture of turnsole, and lime water; if it catches fire, and has a fœtid smell, it is sulphurated hydrogen gass; if it extinguishes the taper, reddens turnsole, and precipitates lime water, it is the carbonic acid; lastly, if it maintains combustion without taking fire, is without smell, and alters neither turnsole nor lime water, it is atmospheric air. It may happen that this fluid may be purer than the air of the atmosphere: in this case its degrees of purity may be judged by the manner in which it maintains combustion, or by mixing it with nitrous or hydrogen gass, in the eudiometers of Fontana and Volta. The process used in obtaining gaseous matters contained in waters is entirely modern. A moistened bladder was formerly used, which was adapted to the neck of a bottle filled with mineral water: the fluid was agitated, and by the swelling of the bladder, an estimate was made of the quantity of gass contained in the water. This method is now known to be fallacious, because water cannot give out all its gass but by ebullition, and because the sides of the moistened bladder alter and decompose the elastic fluid obtained. It is scarcely necessary to remark, that the phenomena exhibited by the water, during the escape of the gass, must be carefully examined, and that a less quantity of water may be exposed to distillation, in proportion as its taste and sparkling indicate that it contains a larger quantity of gass.

Such is the method recommended by modern chemists to obtain the elastic fluids combined with waters: it must be observed, 1. That this process cannot be depended on, with regard to acidulous waters, unless the pressure of the atmosphere, and the state of compression of the elastic fluid under the glass vessels, be more accurately accounted for: and as this is not easily done, the absorption of carbonic acid by lime water, proposed by Gioanetti, appears to be preferable. 2. Though it has been recommended by Bergman to obtain sulphurated hydrogen gass from sulphureous waters, it does not answer, because the heat of ebullition decomposes the gass, and it is likewise decomposed by the mercury, which is converted into ethiops, as soon as it comes in contact with this elastic fluid: for this reason, litharge should be used to absorb this gass in the cold, and to deprive sulphureous waters of their sulphur.

Examination of Mineral Waters by Evaporation.—Evaporation is generally considered as the most certain method of obtaining all the principles of mineral waters. We have before observed, and here repeat, that the experiments of Venel and Cornette show, that long continued ebullition may decompose saline matters dissolved in water, and for that reason we have advised the examination of them by re-agents, employed in greater proportions; yet evaporation may afford much information, when used, together with the analysis by re-agents, which ought always to be considered as one of the principal methods of examining waters.

The intention of evaporation being to collect the fixed principles contained in a mineral water, it is obvious, that in order to know the nature and proportion of these principles, a considerable quantity of the water must be evaporated, and so much the more, in proportion as the principles appear to exist in smaller quantities. When the water is thought to contain a large quantity of saline matter, about twenty pounds must be evaporated: if, on the contrary, it appears to hold but a very small quantity in solution, it will be necessary to evaporate a much larger quantity. It is sometimes requisite to perform this operation with several hundred pounds. The nature and form of the vessels in which waters are exposed for evaporation, is not a matter of indifference: those of metal, excepting silver, are altered by water; vessels of glass, of a certain magnitude, are very subject to be broken; but those of glazed smooth pottery are the most convenient, though the cracks in the glaze sometimes cause an absorption of saline matter; vessels of unglazed porcelain, called biscuit, would doubtless be the most convenient, but their price is a considerable obstacle. Chemists have proposed different methods of evaporating mineral waters; some have directed distillation to dryness, in close vessels, in order to prevent foreign substances, which float in the atmosphere, from mixing with the residue; but this method is excessively tedious: others have advised evaporation by a gentle heat, never carried to ebullition, because they supposed that this last heat alters the fixed principles, and carries a portion of them. This was the opinion of Venel and Bergman. Monnet, on the contrary, directs the water to be boiled, because this motion prevents the reception of foreign matters contained in the atmosphere. Bergman avoids this inconvenience, by directing the vessel to be covered, and a hole left in the middle of the cover for the vapours to pass out: this last method greatly retards the evaporation, because it diminishes the surface of the fluid. At the commencement, the heat used must be sufficient to repel the dust; but the greatest difference in the manipulation of this experiment consists in some writers directing that the substances deposited should be separated, as the evaporation proceeds, in order to obtain each pure and by itself; others, on the contrary, direct the operation to be carried on to dryness. We are of the opinion of Bergman, that this last method is the most expeditious and certain; because, notwithstanding the care which may be taken, in the first method, to separate the different substances which are deposited or crystallized, they are never obtained pure, and must always be examined by a subsequent analysis; and the method is besides inaccurate, on account of the frequent filtrations, and the loss it occasions. Lastly, it is very embarrassing, and renders the evaporation much longer. Mineral waters may therefore be evaporated to dryness, in open glass vessels, on the water-bath, or still more advantageously in glass retorts, on a sand-bath.

Various phænomena are observed during this operation; if the water be acidulous, it emits bubbles, as soon as the heat first begins to act; in proportion as the carbonic acid is disengaged, a pellicle is formed, with a deposition of calcareous earth, and carbonat of iron. These first pellicles are succeeded by the crystallization of sulphat of lime; and lastly, the muriats of potash and soda crystallize in tubes at the surface, but the deliquescent are not obtained but by evaporation to dryness.

The residue must then be weighed, and put into a small phial, with three or four times its weight of alkohol: the whole being agitated, and suffered to subside for some hours, must be filtrated, and the alkohol preserved separate. The residue on which the spirit has not acted must be dried in a gentle heat, or in the open air; when perfectly dry it must be weighed, and the loss of weight will show what quantity of calcareous or magnesian muriat was contained, because these salts are very soluble in alkohol. We shall presently speak of the method of ascertaining the presence of these two salts in the spirituous fluid.

The residue, after treatment with alkohol, and drying, must be agitated with eight times its weight of cold distilled water, and filtered. After some hours standing, the residue is to be dried a second time, and boiled half an hour in four or five hundred times its weight of distilled water; this last residue, after filtration, consists of that which cold or boiling water is insufficient to dissolve. The first water contains neutral salts, such as sulphat of soda, or of magnesia; the muriat of soda, or potash and the fixed alkalis, especially soda united with carbonic acid: the large quantity of boiling water scarcely contains any substance but sulphat of lime. There are therefore four substances to be examined, after these different operations on the matter obtained by evaporation. 1. The residue insoluble in alkohol, and in water of different temperatures. 2. The salts dissolved in alkohol. 3. The salts dissolved in cold water. 4, and lastly, Those dissolved in boiling water. We shall now proceed to the experiments necessary to ascertain the nature of these different substances.

1. The residue which has resisted the action of the alkohol and water may be composed of calcareous earth, of carbonat of magnesia and iron, of alumine, and of quartz. These two last substances are seldom found in waters, but the three first are very common; the brown, or more or less deep yellow colour, indicates the presence of iron. If the residue be of a white grey, it does not contain this metal. When iron is present, Bergman directs it to be moistened, and exposed to the air till it rusts; in which state vinegar does not act on it. In order to explain the methods of separating these different substances, we will suppose an insoluble residue to consist of the five substances here mentioned; it must first be moistened, and exposed to the rays of the sun; and when the iron is perfectly rusted, the residue must be digested in distilled vinegar. This acid dissolves the lime and magnesia, and by evaporation affords the calcareous acetit, distinguishable from the acetit of magnesia, by its not attracting the humidity of the air. They may consequently be separated by deliquescence, or by pouring sulphuric acid into their solution. The latter forms sulphat of lime, which precipitates; but if the magnesian acetit be present, the sulphat of magnesia, composed of magnesia united with the sulphuric acid, will remain in solution, and may be contained by a well conducted evaporation. To ascertain the quantity of magnesia and calcareous earths contained in this residue, sulphat of lime is first to be precipitated: and the sulphat of magnesia, formed by the sulphuric acid poured into the acetous solution, must then be precipitated by carbonat of potash. The quantities of these precipitates are known by weighing. When the chalk and magnesia of the residue are thus separated, the iron, the alumine, and the quartz remain. The iron and the alumine are dissolved by pure muriatic acid, from which the former is precipitated from prussiat of lime, and the latter by carbonat of potash. These precipitates must likewise be weighed. The matter which remains after the separation of the alumine and iron is usually quartorse; its quantity may be known by weighing, and its habitudes by fusion of the blow-pipe with carbonat of soda. Such are the most accurate processes, recommended by Bergman, for examining the insoluble residue of waters.

2. The alkohol used in washing the solid residue of mineral waters must be evaporated to dryness. Bergman advises treating it with sulphuric acid diluted with water, in the same manner as the acetous solution before spoken of; but it must be observed, that this process serves only to exhibit the bases of these salts. To determine the acid, which is ordinarily united with magnesia or lime, and sometimes with both, a few drops of concentrated sulphuric acid must be poured on, which excites an effervescence, and disengages the muriatic gass, known by its smell and white vapour, when the salt under examination contains that acid. This may likewise be known by dissolving the whole residue in water, and adding a few drops of the nitric solution of silver. The nature of the base, which, as we have observed, is either lime, magnesia, or both together, is known by the name of the sulphuric acid, by a similar process with that already explained respecting the acetous solution.

3. The water used in washing the first residue of the mineral water, performed as before directed, with eight times its weight of cold distilled water, contains neutral alkaline salts, such as sulphat of soda, muriats, or marine salts, carbonat of potash, and of soda, and sulphat of magnesia: a small quantity of sulphat of iron is sometimes found. These salts never exist altogether in waters: the sulphat of soda, and the carbonat of potash, are very seldom found; but marine salt is frequently met with, together with carbonat of soda. The sulphat of magnesia is likewise frequently met with, and some waters even contain it in considerable quantities. When the first washing of the residue of a mineral water contains only one kind of neutral salt, it may easily be obtained by crystallization, and its nature ascertained from its form, taste, and the action of fire, as well as that of the re-agents: but this case is very rare, for it is much more usual to find many salts united in this lixivium. They must therefore be separated, if practicable, by slow evaporation; but as this method does not always perfectly succeed, however carefully this evaporation be conducted, it will be necessary to re-examine the salts obtained at the different periods of the evaporation. Carbonat of soda is usually deposited confusedly with the muriatic salts, but they may be separated by a process, pointed out by M. Gioanetti,

It consists in washing this mixed salt with distilled vinegar; for this acid dissolves the carbonat of soda. The mixture must then be dried, and washed a second time with alkohol, which takes up the acetit of soda, without acting on marine salt. The spirituous solution being evaporated to dryness, and the residue calcined, the vinegar becomes decomposed and burns. Soda alone remains, whose quantity may be then accurately determined.

4. The water used in the quantity of four or five hundred times the weight of the residuum of the mineral water contains only sulphat of lime. This may be ascertained by pure caustic ammoniac, which ocasions no change, while caustic potash precipitates it abundantly. By evaporation to dryness, the quantity of earthy salt contained in the water may be accurately ascertained.

Artificial Mineral Waters.—The numerous processes we have prescribed for examining the residues of mineral waters by evaporation serve to ascertain, with the greatest precision, all the several matters held in solution in these fluids. Another process remains to be made to prove the success of the analysis, viz. That of imitating nature in the way of synthesis, by dissolving in pure water the different substances obtained by the analysis of mineral water which has been examined. If the artificial mineral water has the same taste, the same weight, and exhibits the same phænomena with re-agents as the natural mineral water, it is the most complete, and the most certain proof that the analysis has been well made. This artificial combination has likewise the advantage of being procured in all places at pleasure, and at a trifling expence; and is even in some cases superior to the natural mineral waters, for their whole properties may be changed by carriage, and other circumstances. The most celebrated chemists are of opinion, that it is possible to imitate mineral waters. Macquer has observed, that since the discovery of the carbonic acid, and the property it is found to possess of rendering many substances soluble in water, it is much more easy to prepare artificial mineral waters. Bergman has described the method of composing waters which perfectly imitate that of Spa, Sheltzer, Pyrmont, &c. He likewise informs us, that they are used with great success in Sweden, and that he himself has experienced their good effects. Duchanoy has published a work, in which he has given a number of processes for imitating all the mineral waters usually employed in medicine. We may therefore hope, that chemistry may render the most essential service to the art of healing, by affording valuable medicines, whose activity may be increased or diminished at pleasure.

In order to present the reader, under one point of view, with the most conspicuous features in the composition of the mineral waters of this and some other countries, the following synoptical table is subjoined, from Dr. Saunders' work on this subject.

The reader will please to observe, that under the head of *Neutral Purging Salts* are included the sulphats of soda and magnesia, and the muriats of lime, soda, and magnesia. The power which the earthy muriats may possess of acting on the intestinal canal is not quite ascertained, but from their great solubility, and from analogy with salts, with similar component parts, we may conclude that this forms a principal part of their operation.

The reader will likewise observe, that where the spaces are left blank, it signifies that we are ignorant whether any of the substance at the head of the column is contained in the water; that the word *none* implies a certainty of the absence of that substance; and the term *uncertain* means that the substance is contained, but that the quantity is not known.

For the several mineral waters, consult their respective heads, as MALVERN, MOFFAT, SPA WATERS, &c.

A SYNOPTICAL TABLE, *shewing the Composition of* MINERAL WATERS.

CLASS.	NAME.	Highest temperature. Fahrenheit.	Contained in an English wine pint of 28.875 cubic inches. Azotic gas. cubic inches.	Carbonic acid, gass. cubic inches.	Sulphurated hydrogen. cubic inches.	Carbonated soda. grains.	Neutral purging salts. grains.	Selenite & earthycarbonates. grains.	Oxyd of iron. grains.

* That is, 2.94 contained in the sulphat of iron, (this salt when crystallized containing 28 per cent. of oxyd of iron, according to Kirwan) and 1.875 additional of oxyd of iron.

MI'NERALIST. *s.* (from *mineral.*) One skilled or employed in minerals (*Boyle*).

MINERA'LOGIST. *s.* (*mineralogie*, Fr.) One who discourses on minerals (*Brown*).

MINERALOGY. (from *minera*, Latin, a metallic vein; and λογος, Greek, a treatise or discourse.) The science of minerals or fossils. The term, however, is intrinsically barbarous, as being composed of two distinct languages, and might be advantageously exchanged for oryctology, but that it has obtained too extensive an introduction into almost all modern languages to be conveniently relinquished or altered.

So far as this science is connected with the arts of the jeweller and lapidary, it may be said to be nearly coeval with the world; for amongst the earliest historical records we meet with frequent references to the use of various metals and precious stones. The writings of Pliny, Theophrastus, and Dioscorides, unfold to us a very extensive degree of information concerning the knowledge of the Greeks and Romans in the same branch of natural history. But in none of these do we meet with any thing like a systematic arrangement; so that the first mineralogist who has any pretensions to a scientific study of fossile substances is George Agricola of Saxony: he first investigated their external characters, and judiciously defined and described them. His arrangement consists of two classes, first, simple or homogeneous minerals, subdivided into the four orders of terra, succus concretus, lapis and metallum; and second, heterogeneous minerals, subdivided into the orders of compound and mixt.

Cardan published his celebrated treatise very soon afterwards. He differs chiefly from Agricola in separating the saline from the inflammable bodies. Keatman's work De omni rerum Fossilium genere, Gemmis, Lapidibus, Metallis, &c. published in 1665, is nearly a transcript of Agricola, De Natura Fossilium. It contains, however, the addition of a treatise on petrifactions. Cæsalpinus, the botanist, and Bootius Von Boot, has already published their respective works on metals and precious stones, but they contain nothing of importance. The work, however, of a Mexican priest Alonzo Barba, written in Spanish about the same time, is entitled to a more minute notice as accurately describing the mode of working minerals, and as being the first treatise on amalgamation. This work is entitled De los Metallos. Aldrovandus followed shortly afterwards with his Museum Metallicum, a compilation extracted from Agricola, Cardan, and Cæsalpinus; and first drew the attention of mineralogists in any considerable degree to the subject of petrifactions. Aldrovandus was followed by Johnstone, in his Notitiæ Regni Mineralis, published in 1667, and by the celebrated jesuit Athænasius Kircher, in his Mundus Subterraneus, published in 1678. A few years afterwards Woodward published his Catalogue of Minerals, and may be regarded as the first English mineralogist of note.

In 1708, Becher published at Leyden his Physica Subterranea, in which he endeavoured to arrange minerals according to their constituent parts. He was the first writer who proposed the opinion that the difference in composition of earths and stones might be employed in their arrangement and discrimination; and first introduced the division of metals into perfect and imperfect. Bromel, who was a scholar of Becher's, improved upon this arrangement, and arranged sulphur and bituminous bodies in one common class. In the beginning and towards the middle of the same century, Beyer, Büttner, and Scheuchzer, employed themselves principally in the investigation of that highly interesting class of bodies petrifactions. And although their works are disfigured by many idle speculations, and the individual species are but indifferently ascertained, yet from this period the attention of mineralogists was more largely directed to an examination of vast masses of rocks, and other mountainous aggregations.

In 1730, Magnus Von Bromel, a scholar of Hiœrne and Boerhaave, published his celebrated System of Minerals, which was divided into the following orders.

I. Earths.
II. Salts.
III. Sulphurs.
IV. Stones.
1. Resisting the action of fire.
2. Calcinable.
3. Vitrifying in fire.
4. Figured.
V. Petrifactions.
VI. Calculi.
VII. Semi-metals.
VIII. Metals.

This method, however, can hardly be called a system; for the inventor has omitted the classification, generic character, specific differences, and the synonyms of authors. He separates sand from earths; sulphurs from pyrites; refers serpentine to the marbles; and arranges mica with the calcareous earths.

In 1736 Linnéus published the first sketch of his mineral system; he republished it in an improved form in 1748, and added his finishing hand to it in 1768, when it stood as follows:

Class I. Rocks.

Order I. *Humosa.*
Gen. 1. Schist.

Order II. *Calcareous.*
Gen. 2. Marble.
3. Alabaster.
4. Stirium.
5. Spar.

Order III. *Argillaceous.*
Gen. 6. Talc.
7. Amiant.
8. Mica.

Order IV. *Arenate.*
Gen 9. Sandstone.
10. Quartz.
11. Silex.

Order V. *Aggregate.*
Gen. 12. Stone.

Class II. Minerals.

Order I. *Salts.*
Gen. 13. Nitre.
14. Natrum.
15. Borax.
16. Muria.
17. Alumen.
18. Vitriol.

Order II. *Sulphurs.*
Gen. 19. Ambergris.
20. Amber
21. Bitumen.
22. Pyrites.
23. Arsenic.

Order III. *Metals.*

Gen. 24. Quicksilver.
25. Molybdænum.
26. Antimony.
27. Zinc.
28. Bismuth.
29. Cobalt.
30. Tin.
31. Lead.
32. Iron.
33. Copper.
34. Silver.
35. Gold.

CLASS III. FOSSILS.

Order I. *Petrifactions.*

Gen. 36. Zoolite.
37. Ornitholite.
38. Amphibiolite.
39. Ichthyolite.
40. Entomolite.
41. Helmintholite.
42. Phytolite.
43. Grapholite.

Order II. *Concrete.*

Gen. 44. Calculus.
45. Tartar.
46. Eagle-stone.
47. Pumice-stone.
48. Stalactite.
49. Toph.

Order III. *Earths.*

Gen. 50. Ochre.
51. Sand.
52. Clay.
53. Calx.
54. Soil.

This system is faulty in many respects; it has the merit however of having first drawn the attention of mineralogists to the study of the crystalline figures of minerals. Independently of which, although Linnéus cannot be said to have contributed much to the progress of mineralogy, yet indirectly his labours in the other branches of natural history laid the foundation of that reformation which was effected by subsequent mineralogists. He was the first who established right ideas of system, and showed that its principal object was to assist the memory, and to enable naturalists to distinguish bodies from one another, and thus to ascertain if the respective subjects of their investigation have been previously described by others. He also has the merit of having taught that no system can be of use that does not possess an uniformity in the basis of its classification and nomenclature, and a fixed and generally received language.

In the midst of the career of Linnéus, mineralogical chemistry was much advanced by the labours of Pott and Henckel; and especially of the former. Pott arranged earthy minerals according to their proportion of ingredients, and thus paved the way for many of the chemical systems of the present day. His four classes are the alkaline, siliceous, argillaceous and gypseous. An early death prevented this indefatigable chemist from extending his enquiries to the metals.

Waller, the contemporary of Linnéus, and professor of mineralogy at Upsal, published a system of much repute at Stockholm in 1747, and republished it with additions in 1772. The classes and orders were as follows:

I. EARTHS.
1. Dry.
2. Tenacious.
3. Mineralized.
4. Hard.

II. STONES.
1. Calcareous.
2. Vitrescent.
3. Fusible.
4. Apyrous.
5. Rocks.

III. MINERALS.
1. Salts.
2. Sulphurs.
3. Semi-metals.
4. Metals.

IV. CONCRETE.
1. Porous.
2. Petrifactive.
3. Figured.
4. Calculous.

In this system the external characters of the species were more accurately detailed than in any hitherto advanced; the terminology was improved, and the synonyms of preceding authors were elucidated. Waller was the first who subjected to a serious examination the principles on which mineralogists had hitherto arranged minerals. He rejected the characters drawn from use, value, and geological situation; and contended that classes, orders, and genera, should be arranged according to chemical, but species chiefly in conformity with the external characters.

In the interval between Waller's first and second edition of his system appeared those of Woltersdorf, a disciple of Pott; Cronstedt, Lehman, Vogel, Cartheuser and Just; none of which, however, excepting Cronstedt, which appeared in 1758, is entitled to a detailed notice. Cronstedt's system is built upon the following form:

I. EARTHS.
1. Calcareous.
2. Siliceous.
3. Granative.
4. Argillaceous.
5. Micaceous.
6. Fluors.
7. Asbestine.
8. Zeolithic.
9. Magnesiate.

II. SALTS.
1. Acids.
2. Alkalines.

III. PHLOGISTIC.

IV. METALS.
1. Perfect.
2. Imperfect.

This system is chiefly metallurgic; investigated upon chemical principles, peculiar and not compiled. It excludes many genera, as sand-stone, schist, soil, toph, stalactite, eagle-stone, calculus, nitre. Pumice-stone, rock, and petrifactions are added in an appendix. The author denies that crystals originate from salts, and considers their figures to be rather curious than useful. He doubts whether the colours of gems have their origin from metals; believes that calx existed before animals and vegetables; denies that the strata of the earth are regular; and considers characteristic definitions as useless.

MINERALOGY.

Our limits will not permit us to descant on the numerous systems that have since flowed in rapid succession. We shall only observe that the best of them are successively those of Veltheim, Bergman, Kirwan, Werner, Schmeisser, Babington, Gmelin, and Brogniast: and confine our remarks to the two which have been most extensively studied, namely, Werner's and Gmelin's.

Of these two we have selected the last, as offering the best text-book for the Pantologia: not, however, that we would recommend it in preference to the student who wishes to become deeply and extensively versed in mineralogy, but as being simpler and more comprehensible to the general reader. We shall begin therefore with this, though published a few years later in order of time, and shall close our article with a succinct epitome of the general scope and system of Werner, and of the improvements it has received from several illustrious scholars of this justly celebrated school.

The system of Gmelin is little more than an improvement upon that of Linnéus: it was published at Leipsic in 1793, and consists of the five following classes, instead of four, to which Linnéus had limited the subject.

CLASS I. EARTHS.

A. SIMPLE.

Order I. TALCOSE.
α. Greasy.
1. Talcum.
β. Dry and meager.
2. Serpentinus.
3. Asbestus.
4. Actinotus.
5. Hornblenda.

Order II. PONDEROUS.
6. Barytes.
7. Crossopetra.
8. Strontia.
9. Sydneya.

Order III. CALCAREOUS.
α. Purer.
10. Creta.
11. Tophus.
12. Spathum.
13. Schistolithus.
14. Inolithus.
15. Stalactites.
16. Pisolithus.
17. Marmon.
β. Less pure.
†. Effervescing.
18. Suillus.
19. Tremolites.
20. Stellaris.
21. Humus.
22. Marga.
23. Magnesiata.
††. Not effervescing.
24. Gypsum.
25. Hepaticus.
26. Lazarus.
27. Fluor.
28. Apatites.
29. Boracites.

Order IV. ARGILLACEOUS.
30. Aluminaris.
31. Argilla.
32. Puteolana.
33. Cæmentum.
34. Cariosus.
35. Ardesia.
36. Basaltes.
37. Lava.
38. Mica.
39. Opalus.
40. Zeolithus.
41. Scorlus.

Order V. SILICEOUS.
α. Fixed.
†. Impure.
42. Gemma.
43. Olivinus.
44. Felspatum.
45. Pyromachus.
46. Petrosilex.
47. Jaspis.
48. Smiris.
49. Circonius.
50. Amarús.
51. Lydius.
52. Chlorogranatus.
††. Purer.
53. Arena.
54. Quartzum.
55. Chalcedonius.
56. Adamas.

Order VI. ADAMANTINE.
57. Adamantinus.

B. AGGREGATE.

α. With particles more or less crystalline, cohering by no visible intermediate cement.
58. Granites.
59. Gneissum.
β. With heterogeneous fragments immersed in masses of other stones.
60. Perphyrius.
61. Amygdalites.
γ. With fragments of stone conglutinated by a cement.
62. Breccia.
63. Arenarius.

CLASS II. SALTS.

64. Natrum.
65. Borax.
66. Muria.
67. Nitrum.
68. Mirabile.
69. Amarum.
70. Alumen.
71. Vitriolum.

CLASS III. INFLAMMABLES.

72. Turfa.
73. Bitumen.
74. Mellites.
75. Succinum.
76. Ambra.
77. Graphites.
78. Sulphur.

CLASS IV. METALS.

79. Uranium.
80. Wolframum.
81. Magnesium.
82. Stibium.
83. Zincum.
84. Molybdœna.
85. Stannum.
86. Cobaltum.

87. Ferrum.
88. Arsenicum.
89. Cuprum.
90. Niccolum.
91. Bismutum.
92. Argentum.
93. Plumbum.
94. Hydrargyrum.
95. Aurum.
96. Platina.

Appendix.

CLASS V. PETRIFACTIONS.

I. ANIMAL.

α. *Mammals.*
97. Authropolithus.
98. Zoolithus.

ϐ. *Birds.*
99. Ornitholithus.

γ. *Amphibials.*
100. Amphibiolithus.

δ. *Fishes.*
101. Ichthyolithus.

ε. *Insects.*
102. Entomolithus.

ζ. *Worms.*
103. Cenchyolithus.
104. Coralliolithus.

II. VEGETABLE.
105. Phytolithus,

In enumerating the genera we have not added in the present table those of later discovery, because we have been desirous of giving it as published by the author himself. In the general course of our work, however, the reader will find that we have brought the science down to the present day, and have added the recently discovered metals of Osmium, Iridium, Rhodium, Palladium, Chromium, Columbium, Potassium, Sodium, &c. as well as the recent genera under the other classes.

The system of Werner is by far the most comprehensive of all the systems. It contemplates the science of mineralogy under the five following branches, oryctognosy, mineralogical chemistry, geognosy, mineralogical geography, and economical mineralogy.

Oryctognosy is that division of the subject which teaches us to know fossils, and to recognize them whenever they occur to us. It exhibits the different subjects arranged in an order corresponding as nearly as possible with that of their affinities, and distinguished from each other by appropriate denominations, and by determinate and defined characters. The object of mineralogical chemistry is the analysis of fossils, and the discovery of their constituent principles. *Geognosy* treats of the general structure of the earth. It makes us acquainted with the common and particular beds of fossils, with their probable origin, relative formation and arrangement in the earth: with the rocks which compose mountains, and which constitute, if not the solid mass, at least the great shell of the globe. The geognosy of this system is therefore, as we have already had occasion to observe, the geology of natural philosophers in general. (See the article GEOLOGY.) The province of *mineralogical geography* is to describe geographically the scite of fossils in different countries: and that of *economical mineralogy* the various economical purposes to which fossils may be applied.

It is to the first, second, and fourth of these branches of the general science as here laid down, that we confine our view of mineralogy upon the present occasion: the third having been already treated of under the article GEOLOGY, and the fifth entering into the detailed consideration of the individual articles as they occur in the course of the work.

The peculiar excellency of the Wernerian system is the accuracy and determinate power of the language which it has introduced: and in this respect the illustrious author has laudably as well as most successfully followed up the first efforts of Waller upon the same subject. In his classical work, Vonder Renzeichen der Fossilier, he has admirably collected all the old and admitted characters, described others traced by himself on comparing minerals with minerals; defined the characters in common use, given to each an appropriate and fixed determination, and arranged the whole into a systematic order. The system of Werner is now therefore embraced with no small degree of enthusiasm over most parts of Europe, perhaps of the globe: Mr. Kirwan was one of the first who gave it publicity in our own country; M. Brochant, who has very considerably improved upon it, in France; and De la Rio in Spain: and now that it has enlisted into its service the very splendid and important discoveries of Roma de Lisle, and the Abbé Haüy, in the department of crystallography, it bids fair to triumph eventually over all the rest, and perhaps to continue as long as the science shall continue itself.

The following constitute its general principles and arrangement: the classes being four, viz. earths, salts, inflammables, and metals.

1. The earths, earthy fossils, or minerals compose the greater part of the crust of the earth, and generally form a covering to the rest. They are not remarkable for being brittle, heavy, or light-coloured: are little disposed to crystallize; are uninflammable in a low temperature; insipid; and without much smell.

2. The saline minerals are commonly heavyish, soft, and possess some degree of transparency.

3. The inflammables are light, brittle, mostly opake, of a yellow brown, or black colour, seldom crystallize, and never feel cold.

4. The metallic fossils are heavy, generally opake, tough, malleable, cold, not easily inflamed, and exhibit a great variety of colours of a peculiar lustre.

Under each of these classes are various genera, species, sub-species, and varieties, which we shall instance as we proceed. Sometimes, as in the vegetable kingdom, we find a strict affinity between different species of minerals; in which case they constitute or are said to belong to the same family. But in mineralogy one class does not always blend with another in a chemical point of view, nor furnish that beautiful gradation and almost imperceptible union which is to be traced in the other kingdoms of nature.

Antecedently, however, to a full developement of the classification in its different ramfiications, it is necessary to give a brief explanation of the external characters by which minerals are distinguished under this system: for without this neither the individuals nor even the subdivisions themselves would be understood.

External Characters.

These are either generic or specific. The generic characters consist in certain chemical properties of minerals, without any reference to such more palpable differences as colour, lustre, weight, &c.; while these palpable differences form the specific characters.

Generic characters may be general or particular. In the first division are comprehended those that occur in all minerals; in the last those that are found only in particular classes of minerals.

The particular generic external characters are thus advantageously arranged.

1. Colour.
2. Cohesion of particles; distinguished into solid, friable, and fluid.

In solid minerals are to be regarded the external shape, lustre, and surface. When broken, the lustre of the fracture, the fracture itself, and the shape of the fragments are to be noticed. In distinct concretions regard must be paid to the shape of the concretions, their surface, their lustre, transparency, streak and soiling. All these may be ascertained by the eye. By the touch we may discover the hardness of minerals, their tenacity, frangibility, flexibility, their unctuosity, coldness, weight, and adhesion to the tongue. By the ear we distinguish their sound, and by the smell and taste the qualities which these two senses indicate.

In friable minerals, external shape, lustre, aspect of particles, soiling, and degree of friability, are to be attended to.

In fluid minerals the lustre, transparency, and fluidity, are principal objects to be regarded.

The specific external characters of minerals are founded on the distinctions and varieties of the two great generic divisions. And first, of colours, the names of which are derived from certain bodies in which they most generally occur, either in a natural or artificial state, or from different mixtures and compositions of both.

I. Colour.

1. White. This may be snow-white, reddish-white, yellowish-white, silver-white, greyish-white, greenish-white, milk-white, or tin-white.

2. Grey. Lead-grey, blueish-grey, pearl-grey, reddish-grey, smoke-grey, greenish-grey, yellowish-grey, steel-grey, and ash-grey.

3. Black. Greyish-black, brownish-black, dark-black, iron-black, greenish-black, and blueish-black.

4. Blue. Indigo-blue, Prussian-blue, lavender-blue, smalt-blue, sky-blue.

5. Green. Verdegris-green, celaden-green, mountain-green, emerald-green, leek-green, apple-green, grass-green, pistachio-green, asparagus-green, olive-green, blackish-green, canary-green.

6. Yellow. Sulphur-yellow, lemon-yellow, gold-yellow, bell-metal yellow, straw-yellow, wine-yellow, Isabella-yellow, ochre-yellow, orange-yellow, honey-yellow, wax-yellow, brass-yellow.

7. Red. Morning-red, hyacinth-red, brick-red, scarlet-red, copper-red, blood-red, carmine-red, cochineal-red, crimson-red, columbine-red, flesh-red, rose-red, peach-blossom-red, cherry-red, brownish-red.

8. Brown. Reddish-brown, clove-brown, hair-brown, yellowish-brown, tombac-brown, wood-brown, liver-brown, blackish-brown.

Besides these distinctions, colours may be clear, dark, light, or pale; they may have a tarnished appearance, a play, a changeability, an iridescence, an opalescence, a permanent alteration, and a delineation of figure or pattern, such as dotted, spotted, clouded, flamed, striped, veined, dendritic, or ruiniform.

II. Cohesion of Particles.

Minerals are divided into, 1. Solid, or such as have their parts coherent, and not easily moveable; 2. Friable, or that state of aggregation in which the particles may be overcome by simple pressure of the finger; and 3. Fluid, or such as consist of particles which alter their place in regard to each other by their own weight.

1. *Solid Minerals.*

External aspect has three things to be regarded, 1. The shape; 2. The surface; and 3. The lustre. The external shape again may be common, particular, regular, or extraneous; and hence arise the specific differences.

1. The common external shape may be massive; disseminated coarsely, minutely, or finely; in angular pieces, sharp-cornered or blunt-cornered; in grains, large, coarse, small, fine, angular, flat, round; in plates, thick or thin; in membranes or flakes, thick, thin, or very thin.

The particular external shape may be longish, as dentiform, filiform, capillary, reticulatic, dendritic, coralliform, stalactitic, cylindrical, tubiform, claviform, or fruticose; roundish, as globular, spherical, ovoidal, spheroidal, amygdaloidal, botryoidal, reniform, tuberose, or fused-like; flat, as specular, or in leaves; cavernous, as cellular in various forms, with impressions, perforated, corroded, amorphous, or vesicular; entangled, as ramose, &c.

In the regular external shape or crystallization are to be regarded its genuineness, according to which it may be either true or supposititious; its shape, made up of planes, edges, angles, in which are to be observed the fundamental figure and its parts, the kind of fundamental figure, the varieties of each kind of fundamental figure, with their accidents and distinctions, and the alterations which the fundamental figure undergoes by truncation, by bevelment, by acumination, or by a division of the planes. There are a variety of figures under each of these subdivisions.

It must be remarked also, that the external shape may be extraneous, or derived from the animal and vegetable kingdoms, as in fossils and petrifications.

2. The external surface contains several varieties of distinctions. It may be uneven, granulated, rough, smooth, or streaked in various ways and directions.

3. The external lustre is the third generic external character, and is of much importance to be attended to. In this we have to consider the intensity of the lustre, whether it is splendent, shining, glistening, glimmering, or dull; next the sort of lustre, whether metallic or common. The latter is distinguished into semimetallic, adamantine, pearly, resinous, and vitreous.

Aspect of the Fracture of solid Minerals.

After the external aspect, the fracture forms no inconsiderable character in minerals. Its lustre may be determined as in the external lustre; but the fracture itself admits of great varieties. It may be compact, splintery, coarsely splintery, finely splintery, even, conchoidal, uneven, earthy, hackly. If the fracture is fibrous, we are to consider the thickness of the fibres, if coarse or delicate; the direction of the fibres, if straight or

curved; and the position of the fibres, if parallel or diverging.

In the radiated fracture we are to regard the breadth of the rays, their direction, their position, their passage or cleavage. In the foliated fracture, the size of the folia, their degree of perfection, their direction, position, aspect of their surface, passage or cleavage, and the number of cleavages, are to be noted.

The shape of the fragments may also be very various-regular, as cubic, rhomboidal, trapezoidal, &c. or irregular, as cuneiform, splintery, tabular, indeterminately angular.

Aspect of the distinct Concretions.

The shape of the distinct concretions forms very prominent external characters. They may be granular, different in shape, or in magnitude; they may be lamellar, distinct, concretious, differing in the direction of the lamellæ, in the thickness, with regard to shape, and in the position.

The surface of the distinct concretions may be smooth, rough, streaked, or uneven; as for their lustre, it may be determined in the same manner as the external lustre.

General Aspect as to Transparency.

Minerals, as is well known, have different degrees of transparency, which may be considered among their external characters. They may be transparent, semitransparent, translucent, translucent at the edges, or opaque.

The Streak.

The colour of this external character may be either similar or different. It is presented to us when a mineral is scraped with the point of a knife; and is similar when the powder that is formed is of the same colour with the mineral, as in chalk: or dissimilar or different, as in cinnabar, orpiment, &c.

The Soiling or Colouring

Is ascertained by taking any mineral substance between the fingers, or drawing it across some other body. It may soil strongly, as in chalk, slightly, as in molybdena, or not at all, which is a quality belonging to most of the solid minerals. All the preceding external characters are recognized by the eye.

External Characters from the Touch.

These are eight in number, and are not destitute of utility to the mineralogical student. 1. Hardness; 2. Tenacy; 3. Frangibility; 4. Flexibility; 5. Adhesion to the tongue; 6. Unctuosity; 7. Coldness; 8. Weight.

Hardness may be tried by a capacity to resist the file, yielding a little to it, by being semi-hard, soft, or very soft. Tenacity has different degrees, in substances being brittle, sectile or mild, or ductile. The frangibility consists in minerals being very difficultly frangible, difficultly frangible, easily frangible, or very easily frangible. The flexibility is proved by being simply flexible, elasticly flexible, commonly flexible, or inflexible. The adhesion to the tongue may be strongly adhesive, pretty strongly, weakly, very weakly, or not at all. Unctuosity may be meager, rather greasy, greasy, or very greasy. Coldness is subdivided into cold, pretty cold, rather cold. Weight may be distinguished into swimming or supernatant, light, rather light, heavy, very heavy. The three last divisions from the touch are in the Wernerian system regarded as anomalous; but they seem properly to be classed under this head.

External Characters from the Sound or Hearing.

The different kinds of sound which occur in the mineral kingdom are, 1. A ringing sound, as in native arsenic and thin splinters of horn-stone; 2. A grating sound, as in fresh-burnt clay; 3. A creaking sound, as that of natural amalgam.

2. *Friable Minerals.*

The external characters drawn from minerals of this class are derived, first, from the external shape, which may be massive, disseminated, thinly coating, spumous, or dendritic: secondly, from the lustre, regarded under its intensity, whether glimmering or dull, and its sort, whether common glimmering or metallic glimmering: thirdly, from the aspect of the particles, as being dusty or scaly: fourthly, from soiling or colouring, as strongly or lightly: and lastly, from the friability, which may be loose or cohering.

3. *Fluid Minerals.*

Of external characters drawn from fluid minerals there are only two kinds, which include three varieties; 1. The lustre, which is either metallic, as in mercury, or resinous, as in rock oil. 2. The transparency, which is transparent, as in naphtha; turbid, as in mineral oil; or opaque, as in mercury. 3. The fluidity, which may be fluid, as in mercury, or viscid, as in mountain tar.

External Characters from the Smell.

These may be spontaneously emitted and described, as bituminous, faintly sulphureous, or faintly bitter; or they may be produced by breathing on, and yield a clay-like smell; or they may be excited by friction, and smell urinous, sulphureous, garlick-like, or empyreumatic.

External Character from the Taste.

This character prevails chiefly in the saline class, and it contains the following varieties: a sweetish taste, sweetish astringent, styptic, saltly bitter, saltly cooling, alkaline, or urinous.

Having now given a synoptical view of the external characters of minerals, we shall proceed to their classification, and in this we shall chiefly follow the names and arrangement of professor Jameson.

CLASS I.

EARTHY FOSSILS.

First Genus. DIAMOND.

Diamond.

This precious stone has great variety of shades, exhibiting a beautiful play of colours. It occurs in indeterminately angular and completely spherical grains, which present planes of crystallization, or are actually crystallized. Its fundamental crystal is the octaedron, which passes into various forms. It is hard in the highest degree, brittle, not very difficultly frangible, and has a specific gravity of 3.600.

The diamond has, by modern experiments, been proved to be nearly pure carbon, and begins to burn at 14° or 15° of Wedgewood. See Plate 107. Mineralogy, figs. 1. and 2.

Second Genus. ZIRCON.

First Species. *Zircon.*

The prevailing colour is grey, but it occurs likewise green, blue, red, yellow, and brown, with various intermediate tints.

It is found most commonly in roundish angular pieces, with rounded angles and edges. When crystallized, the figure is generally a rectangular four-sided prism; somewhat flatly acuminated by four planes, set on lateral planes; but of this figure there are several varieties. The crystals are almost always very small, have a smooth surface, bordering on strongly splendent. Internally, the lustre is strongly splendent, passing into adamantine. Fig. 3.

Zircon is hard in a very high degree, brittle, frangible without great difficulty. Specific gravity 4.700. It forms a colourless transparent mass with borax, but is infusible by the blowpipe without addition.

Found in the island of Ceylon, where it was first discovered, and lately in Norway, imbedded in a rock composed of hornblend and felspar.

Frequently cut as a precious stone, and used as an inferior kind of diamond, of which it was once considered as a variety. Its play of colours very considerable.

Second Species. Hyacinth.

The chief colour is red, passing to reddish-brown, and to orange-yellow. The figure a rectangular four-sided prism, flatly acuminated by four planes, which are set in the lateral edges. Of this figure, however, several varieties occur.

The crystals are generally small, and always imbedded. The lateral planes smooth, and externally shining. Internally it is splendent and glassy, inclining somewhat to resinous.

The hyacinth is transparent, very hard, frangible without particular difficulty, feels a little greasy when cut, and has a specific gravity of about 4.000.

Is fusible with borax. Exposed to the blowpipe it loses its colour, but not its transparency.

Occurs in rocks of the newest floetz trap formation, and sometimes in sand. Is a native of Ceylon, the country of gems; of Spain, of Portugal, France, Italy, Saxony, and probably Scotland.

It takes a fine polish, and when the colours are good, it is highly valued. A third species, called cinnamon stone, has lately been discovered at Columbo, in Ceylon.

Third Genus. FLINT.

First Species. Chrysoberyl.

The prevailing or general colour is asparagus-green, passing into a variety of allied shades. It exhibits a milk-white light; occurs in roundish and angular grains, which sometimes approach in shape to the cube. It is seldom crystallized; but when in this state it commonly presents a longish six-sided table, having truncated lateral edges, and longitudinally streaked lateral planes. The crystals are small, externally shining, and internally splendent. Fig. 4.

It is hard, brittle, not very easily frangible, with a specific gravity of 3.600. Without addition it is infusible.

The chrysoberyl is found in Brazil, and in the sand of Ceylon. It is sometimes set in rings with a yellow foil, but is rarely in the possession of our jewellers.

Second Species. Chrysolite.

The chief colour is pistachio-green, of all degrees of intensity. It occurs in original angular sharp-edged pieces, with a rough, scaly, splintery surface, and when crystallized exhibits a broad rectangular four-sided prism, with its lateral edges sometimes truncated, sometimes bevilled, and acuminated by six planes. Fig. 5.

The external surface of the crystals is splendent, internally splendent, and vitreous.

Third Species. Olivine.

The colour is generally asparagus-green, of various degrees of intensity. It is found imbedded also in roundish pieces and grains; and when crystallized, which is rare, in rectangular four-sided prisms.

Internally, it is shining, varying between glistening and splendent. It is semitransparent, very easy frangible; in a low degree hard, and not particularly heavy. It is nearly infusible without addition. Occurs imbedded in basalt; is frequently found in Bohemia, and also in Hungary, Austria, France, England, Ireland, Scotland, Sweden, Iceland, and Norway. Pieces as large as a man's head have been found in some parts of Germany.

Fourth Species. Augite.

The general colour is blackish-green. It occurs chiefly in indeterminate angular pieces and roundish grains. Occasionally it is crystallized, and presents broad rectangular six-sided prisms. The crystals are mostly small. Internally the lustre is shining, approaching sometimes to splendent.

The augite is only translucent, and but faintly transparent. It is hard, not very easily frangible, and not particularly heavy.

It is found in basalt, either singly or accompanied with olivine, in Bohemia, Hungary; at Arthur's-seat, near Edinburgh; in some of the Hebrides, and in Norway. From olivine it is distinguished by its darker colours, the form of its crystallization, and its greater hardness.

Fifth Species. Vesuviane.

Its principal colour is dark olive-green, passing into other allied shades. It occurs massive, and often crystallized in rectangular four-sided prisms. The crystals are mostly short, and placed on one another. Externally their surface alternates between glistening and splendent. Internally they are glistening, with a lustre between vitreous and resinous.

The vesuviane is translucent, hard in a moderate degree, and approaching to heavy. Before the blow-pipe it melts without addition.

It is found among the exuviæ of Vesuvius, from whence it derives its name, in Siberia and Kamtschatka. At Naples, it is cut into ring-stones, and sold under various names.

Sixth Species. Leuzite.

The colours are yellowish and greyish-white. It occurs mostly in original round and angular grains. When crystallized, it exhibits acute double eight-sided pyramids. Internally it is shining, and approaching to glistening, with a vitreous lustre, inclining somewhat to resinous.

The leuzite is translucent and semitransparent. It is hard in a low degree, brittle, easily frangible, and not very heavy. It is infusible without addition. With borax, it forms a brownish transparent glass.

It is found in rocks of the newest floetz trap formation, particularly in basalt, near Naples, and in the vicinity of Rome. Bergman gave it the name of white garnet; but Werner has ascertained it to be a distinct species of itself.

Seventh Species. Melanite.

The general colour is velvet-black. It occurs crystallized in a six-sided prism. The crystals are middle-sized or small. Externally they are smooth and shining, approaching to splendent; internally shining, inclining to glistening.

The melanite is opaque, hard, pretty easily frangible, and not very heavy. It occurs imbedded in rocks of the newest floetz trap formation, and hitherto has been found only at Frescati and St. Albano, near Rome.

Eighth Species. Garnet.

This is divided into two sub-species, the precious garnet and the common garnet. See GARNET, and fig. 6.

Ninth Species. Pyrope.

The colour is dark blood-red. It occurs in small and middle-sized roundish and angular grains; but never crystallized. Its lustre is splendent and vitreous. It is completely transparent, hard so as to scratch quartz, and not particularly heavy.

The pyrope is found imbedded in serpentine in Saxony and Bohemia. In Fifeshire, Scotland, it is found in the sand on the sea shore. It is employed in various kinds of jewellery, and is generally set in a good foil.

Tenth Species. Grenatite.

The colour is a dark reddish-brown. It is always crystallized in broad six-sided prisms. The crystals are small and middle-sided, internally glistening, with a lustre between vitreous and resinous.

The grenatite varies from opaque to translucent, is hard, brittle, easily frangible, and not particularly heavy.

It is found imbedded in mica slate, in St. Gothard, Switzerland; and is also met with in Britanny and in Spain.

Eleventh Species. Spinelle.

The predominant colour is red, which passes on into blue, green, yellow, and brown. It occurs in grains, and likewise crystallized in octaedrons with several variations. The crystals are very rarely middle-sized. Externally and internally the lustre is splendent and vitreous.

The spinelle alternates from transparent to vitreous: it is hard in a pretty high degree, and approaches to heavy. It is fusible with borax: occurs in rocks belonging to the newest floetz trap formation; and is found in Pegu and Ceylon. It is used as a precious stone, and considerably valued, though possessing neither the hardness nor the fire of the oriental ruby.

Twelfth Species. Sapphire.

The principal colour Berlin blue; but it is found also red, with all the intermediate shades between these two colours. It occurs in small rolled pieces, and crystallized in double three-side pyramids, of which there are several varieties in figure.

The crystals are small and middle-sized. Internally the lustre is splendent and vitreous. It is more or less transparent in different specimens. Some varieties, when cut, exhibit a star of six rays. Fig. 7.

The sapphire is hard in the highest degree, but yields to the diamond; it is easily frangible, and rather heavy, having a specific gravity of about 4.000.

It is infusible without addition: occurs in rocks of the newest floetz trap formation, and is supposed to be an inmate of granite, syenite, and other primitive rocks.

This precious stone is found in the utmost beauty in Pegu and Ceylon. It is also a native of Portugal, of France, and of Bohemia. Next to the diamond, it is the most valuable of gems, and is used in the finest kind of jewellery.

It should be observed, that the violet-coloured sapphire is the oriental amethyst; that the yellow is the oriental chrysolite and topaz; and that the green is the oriental emerald.

Thirteenth Species. Corundum.

The principal colour is a greenish-white, of various degrees of intensity. It occurs massive, disseminated, in rolled pieces, and crystallized. The crystallizations resemble those of the sapphire, and the crystals are middle-sided and imbedded.

The corundum is duplicating translucent, hard in a high degree, pretty easily frangible, and approaches to heavy. It is supposed to occur imbedded in granite, syenite, or green-stone, and is found in the Carnatic and on the coast of Malabar. See CORUNDUM.

Fourteenth Species. Diamond Spar.

The colour is a dark hair-brown. It occurs massive, disseminated, in rolled pieces, and crystallized in six-sided prisms, or very acute six-sided pyramids. Internally, its lustre is splendent, approaching in a slight degree to adamantine. It may be cut so as to present an opalescent star of six rays, of a peculiar pearly light.

It is translucent on the edges, hard in a high degree, easily frangible, and not particularly heavy.

The diamond spar probably occurs in granite. It has hitherto been found only in China. Both this stone and corundum are employed in cutting and polishing hard minerals, and they seem to be nearly allied to each other.

Fifteenth Species. Emery.

Emery is hard in the highest degree, not very easily frangible, and is heavy. It occurs in beds of talc and steatite, and is frequently accompanied with calcspar and blende. It is found in Saxony, in the islands of the Archipelago, in Spain, Normandy, and is said also to be a native of the isles of Guernsey and Jersey.

It is of great use in cutting and polishing hard bodies.

Sixteenth Species. Topaz.

The chief colour is a wine-yellow, of all degrees of intensity. It is found massive, disseminated, and sometimes rolled, but most commonly crystallized in oblique eight-sided or four-sided prisms, which exhibit several varieties. The crystals are small and middle-sized, externally splendent; internally splendent, and shining: lustre vitreous.

The topaz alternates from translucent to transparent, and is duplicating transparent. It is hard in a high degree, easily frangible, and is not particularly heavy. It is fusible with borax; and some kinds in a gentle heat turn white, and are sometimes sold for diamonds.

It is commonly found in veins that traverse primitive rocks in Brazil, Siberia, in Pegu, and Ceylon; in Bohemia, Saxony, and in Cornwall. Exhibiting various forms and tints, it has often been confounded with other precious stones. It is much used in seals and rings.

Seventeenth Species. Emerald.

The green called emerald is the characteristic colour of this species, but it has all degrees of intensity from deep to pale. It is said to occur massive and in rolled pieces, but most commonly crystallized in low equiangular six-sided prisms. The crystals are middle-sized and small. Internally the lustre is intermediate between shining and splendent, and is vitreous. It alternates from transparent to translucent, and is duplicating transparent.

The emerald is hard, not particularly heavy, melts easily with borax, but is scarcely fusible before the blow-pipe. It occurs in veins that traverse clay-slate, and at present is only found in South America, particularly in Peru, though the Romans are said to have procured it from Egypt and Ethiopia.

From the beauty and vivacity of its colour, the charming emblem of the vegetable kingdom, this precious stone is much admired, and employed in the most expensive kinds of jewellery. See EMERALD.

Eighteenth Species. Beryl.

This is divided into two sub-species, the precious and the schorlous beryl. See BERYL, and fig. 8.

Nineteenth Species. Schorl.

This is divided into two sub-species, common schorl and tourmaline.

Twentieth Species. Thumerstone.

The colour is commonly clove-brown, of various degrees of intensity. It is occasionally found massive, more frequently disseminated; but generally crystallized in very flat and oblique rhombs. Externally, its lustre is generally splendent; internally, it alternates from glistening to shining, and is vitreous.

This species alternates from perfectly transparent to weakly translucent. It is pretty hard, very easily frangible, and not particularly heavy. It appears to be peculiar to the primitive mountains, and is found imbedded in limestone in Saxony, Dauphiny, Norway, Siberia, and Cornwall.

Twenty-first Species. Iron-Flint.

The colour a yellowish-brown, bordering on liver-brown. It occurs commonly massive, but also crystallized in small equiangular six-sided prisms. Externally, its lustre is splendent; internally, shining, and is intermediate between vitreous and resinous.

Iron-flint is opaque, and slightly translucent on the edges. It is pretty hard, somewhat difficultly frangible, and approaching to heavy. It occurs in iron-stone veins, and is found in Saxony, and, according to Karsten, at Bristol. It renders the iron ore, along with which it is dug, very difficult of fusion.

Twenty-second Species. Quartz.

Werner divides this into five sub-species, amethyst, rock crystal (fig. 9.), milk-quartz, common quartz, and prase. The first sub-species is again subdivided into common amethyst and thick fibrous amethyst. See QUARTZ, AMETHYST, &c.

Twenty-third Species. Horn-Stone.

Horn-stone is divided into three sub-species, splintery horn-stone, conchoidal horn-stone, and wood-stone.

First Sub-species. Splintery Horn-Stone.

The common colour grey, but often red, with various shades of each. It is usually found massive, or in large balls. Internally its lustre is dull; but glimmering when it approaches to the nature of quartz. It is more or less translucent on the edges, hard, brittle, very difficultly frangible, and not particularly heavy.

The substance is infusible without addition; and is found in the shape of balls in lime-stone, and sometimes forming the basis of porphyry. It is a native of Bavaria, Sweden, and the Shetland islands; and appears to differ from quartz in containing a larger proportion of alumina.

Second Sub-species. Conchoidal Horn-Stone.

The colour runs from greyish-white to yellowish and greenish-white. It occurs massive. Internally, it is a little glistening, strongly translucent on the edges, hard, easily frangible, and not particularly heavy.

Conchoidal horn-stone is found in beds or in veins, accompanied with agate, at Goldberg, in Saxony.

Third Sub-species. Wood-Stone.

The prevailing colour is ash-grey, but with many different shades. Its shape is exactly conformable to its former woody form, whether trunk, branches, or roots. Internally, it is sometimes dull, and sometimes glimmering and glistening; slightly translucent on the edges, pretty hard, easily frangible, and not particularly heavy.

It is found insulated in sandy loam in Saxony, Bohemia, Russia, Hungary, and at Loch Neagh in Ireland. It receives a good polish, and is applied to the same purposes as agate.

Twenty-fourth Species. Flint.

The general colour is grey, but with many varieties. It occurs massive, in regular plates, in angular grains and species, in globular and elliptical rolled pieces, in the form of sand, and tuberose and perforated. Sometimes it is crystallized, when it exhibits double six-sided prisms, or flat double three-sided pyramids. Internally, the lustre is glimmering, translucent on the edges, hard, easily frangible, and not particularly heavy.

Twenty-fifth Species. Chalcedony.

This is divided into two sub-species, chalcedony and cornelian.

First Sub-species. Common Chalcedony.

The most common colour is grey. The external shape is various, being massive, in blunt-edged grains and rolled pieces, in original round balls, &c. &c. Internally, the chalcedony is almost always dull, commonly semitransparent, hard, brittle, rather difficultly frangible, and not particularly heavy. It occurs in ampydaloid, and in porphyry; and is found in Transylvania, in Iceland, Siberia, Cornwall, Scotland, and the Hebrides. Being susceptible of a fine polish, it is employed as an article of jewellery. See CHALCEDONIUM.

Second Sub-species. Cornelian.

The principal colour is a blood-red, of all degrees of intensity. It commonly occurs in roundish pieces, and also in layers: the lustre is glistening, bordering on glimmering, and is semitransparent. See CORNELIAN, and CHALCEDONIUM.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. Werner therefore has placed them as a supplement to the species chalcedony, which forms a principal constituent part of them, and disposes them according to their colour-delineations, thus: 1. Fortification agate; 2. Landscape agate; 3. Ribbon agate; 4. Moss agate; 5. Tube agate; 9. Clouded agate; 7. Land agate; 8. Star agate; 9. Fragment agate; 10. Punctuated agate; 11. Petrifaction agate; 12. Coal agate; 13. Jasper agate. They are all compounded of chalcedona, cornelian, jasper, horn-stone, quartz, heliotrope, amethyst, indurated lithomarge, and opal, in different quantities and proportions, and are found in great abundance in Germany, France, England, Scotland, Ireland, and the East Indies.

The uses of agate are various. It is cut into vases, mortars, snuff-boxes, seals, handles to knives, and for many other useful purposes. See Agate and Chalcedonium.

Twenty-sixth Species. Heliotrope.

The principal colour is intermediate between leek and dark celadon green, or mountain-green. It occurs massive, and in angular as well as rolled pieces. Internally the lustre is glistening, and is always resinous. It is commonly translucent in the edges; is easily frangible, hard, and not particularly heavy.

Heliotrope is found in rocks belonging to the floetz trap formation, in Asia, Persia, Siberia, Saxony, and Iceland.

On account of its beautiful colour and its hardness, it is employed for nearly the same purposes as agate. See Heliotrope.

Twenty-seventh Species. Plasma.

The usual colour is intermediate between grass and leek-green, and of different degrees of intensity. It occurs in indeterminably angular pieces, which have a rough earthy crust. Internally its lustre is glistening. It is intermediate between semitransparent and strongly translucent, hard, brittle, frangible without great difficulty, and not particularly heavy.

Hitherto it has only been found among the ruins of Rome, and constituted a part of the ornamental dress of the ancient Romans.

Twenty-eighth Species. Chrysopras.

Its characteristic colour is apple-green, of all degrees of intensity. It is found massive in angular pieces, and in thick plates. Internally it is dull; the lustre intermediate between translucent and semitransparent. It is hard, not very difficultly frangible, nor particularly heavy; and is found along with quartz, opal, chalcedony, &c. at Kosemutez, in Lower Silesia.

Chrysopras is principally used for ring-stones, and some varieties are highly esteemed; but it is difficult to cut and polish.

Twenty-ninth Species. Flinty Slate.

This has been divided into two sub-species, common flinty slate, and Lydian stone.

First Sub-species. Common Flinty Slate.

The principal colour is grey, but there are many varieties of shades. It occurs massive in whole beds, and frequently in blunt-angled pieces, with a smooth and glimmering surface. Internally it is faintly glimmering; more or less translucent on the edges; hard, brittle, difficultly frangible, and not particularly heavy.

It occurs in beds in transitive mountains in Saxony, at the lead-hills in Scotland, and other places.

Second Sub-species. Lydian Stone.

The colour is greyish-black, passing into velvet-black. It occurs massive, and is frequently found in trapezoidal-shaped rolled pieces. Internally it is glimmering; opaque, hard, pretty easily frangible, and not particularly heavy. It is found in similar formations with the preceding, near Prague and Carlsbad in Bohemia, in Saxony, and in the Moorfoot and Pentland hills, near Edinburgh.

When polished, it is used as a test-stone for determining the purity of gold and silver; but is less suited for this purpose than basalt, and some kind of clay slate.

Thirtieth Species. Cat's Eye.

The principal colour is grey, of which it presents many varieties. It occurs in blunt-edged pieces, in rolled pieces, and likewise massive. Internally it is shining; usually translucent, and sometimes also semi-transparent. It is hard, easily frangible, and not particularly heavy.

Its geognostic situation is unknown. It is imported from Ceylon and the coast of Malabar; and is usually cut for ring-stones. Some of the varieties are highly valued.

Thirty-first Species. Prehnite.

The colours are various shades of green, white, and yellow. It is sometimes massive, and sometimes crystallized in oblique four-sided tables. Externally, the crystals are smooth and shining; internally, inclining to glistening and pearly.

Prehnite is translucent, sometimes passing into semi-transparent and transparent: it is hard, easily frangible, and not very heavy. It occurs in Dauphiny in viens of the oldest formation; in Scotland in rocks belonging to the newest floetz trap formation; and was first discovered in Africa by colonel Prehn, from whom it receives its appellation.

Thirty-second Species. Zeolite.

This species is divided by Werner into five sub-species, 1. Mealy zeolite. 2. Fibrous zeolite. 3. Radiated zeolite. 4. Foliated zeolite. 5. Cubec zeolite. As they are principally distinguished from each other by fracture, hardness, and lustre, we shall only observe, that the chief colours of all are yellowish, whitish, and reddish, with a variety of intermediate shades; that zeolite occurs massive, in angular pieces, in balls, and sometimes chrystalized in short and oblique four-sided prisms, and in perfect smooth planed cubes; that it is according to the sub-species opaque, translucent, or even transparent; and that it is semi-hard, easily frangible, and not particularly heavy.

Zeolite occurs in rocks belonging to the newest formation, but is sometimes, though rarely, found in primitive green stone, either disseminated, in contemporaneous balls, or lining or filling up air cavities or veins. All the different sub-species are natives of Scotland. The mealy zeolite is found in the Isle of Sky; the fibrous and radiated in the isles of Canary and Sky; the foliated in Staffa, and the cubic in the same isle, and likewise in Sky. They are likewise met with in Iceland, in Sweden, in Germany, and the East Indies.

Thirty-third Species. Cross-stone.

The colour is a greyish-white. It occurs crystalized, either in broad rectangular four-sided prisms, or in twin crystals. The crystals are mostly small, and aggregated on one another. Both the internal and the external lustre is shining, inclining to splendent or glistening.

The cross-stone is translucent passing to transparent, semi-hard, easily frangible, and not particularly heavy. It has hitherto been found only in mineral veins, and in agate-balls at Strontian, in Argyleshire, and at Andreasberg, in Hartz, as well as some other places.

Thirty-fourth Species. Agate-stone.

The colour is a perfect azure blue, of different shades. It is found massive, disseminated, and in rolled pieces. The lustre is glistening and glimmering. It is translucent on the edges, pretty hard, brittle, easily frangible, and not particularly heavy.

The geognostic situation is not correctly ascertained. It is said to have been found near the lake of Baikal, in Siberia, in a vein accompanied with garnet, felspar, and pyrites. It occurs in Persia, China, Tartary, and Siberia; in South America; but in Europe has only been found among the ruins of Rome.

Its beautiful colour renders it an object of attraction, and being capable of receiving a high polish, it is applied to various useful purposes, and enters into the composition of many different ornaments. It is the lapis lazuli of painters. Werner is constantly making additions to his species under every genus.

Of those belonging to the flint genus, which are less known, and have been described with less precision than the preceding, are coccolite, found in Sweden and Norway; pistazite, found in Norway, Bavaria, and France; ceylanite, in Ceylon; enclase, in Peru; hyalite, near Frankfort; menilite, near Paris; lomonite, in Lower Britanny; natrolite, in Suabia; azurite, in Stiria, &c.; andalusite, or hardspar, in Saxony, France, and Spain; chiastolite, or hollow spar, in France and Spain, and probably in Cumberland; scapolite, in Norway; arctizite, or wernerite, in Sweden, Norway, Switzerland; and lazulite.

FOURTH GENUS.

CLAY *Genus.*

First Species. Jasper.

This is divided into six sub-species; Egyptian jasper, striped jasper, porcelain jasper, common jasper, agate jasper, and opal jasper.

Second Species. Opal.

Werner divides this into four sub-species, precious opal, common opal, semi-opal, and wool opal.

Third Species. Pitch-stone.

The colours are black, green, brown, red, and occasionally grey. It occurs always massive in great beds and rocks. Internally, its lustre is shining. It is commonly translucent in a small degree, brittle, and pretty easily frangible.

Pitch-stone is fusible without addition: occurs in beds of the newest porphyry and floetz trap formation; and is found in Saxony, Hungary, in several of the Hebrides, and in Dumfriesshire. Some of its varieties bear a striking resemblance to pitch, from whence it receives its appellation.

Fourth Species. Obsidian.

The principal colour is velvet-black. It always occurs in angularly roundish-pieces. Internally it is splendent. Some of the varieties are translucent, others semi-transparent. It is hard, easily frangible, and not very heavy.

Obsidian occurs insular in the newer porphyry formation, and is found in Hungary, Iceland, in Peru, and various other countries. When cut and polished, it is sometimes used for ornamental purposes, and mirrors for telescopes have been formed of it. It probably owes its origin to fire.

Fifth Species. Pearl-stone.

Its colour is generally grey, sometimes black and red. It occurs vesicular, and the vesicles are long and roundish, with a shining pearly lustre. It is translucent on the edges, not very brittle, very easily frangible, and rather light.

Pearl-stone is found in beds of porphyry, near Tokay, in Hungary, in the north of Ireland, and the Hebrides.

Sixth Species. Pumice-stone.

Its usual colour is a light yellowish-grey, passing into different neighbouring shades. It is small, and lengthened vesicular: its internal lustre glistening, generally translucent in the edges, soft, and seldom semi-hard, very brittle, easily frangible, and swims in fluids.

It occurs in various situations, generally accompanied by rocks that belong to the floetz trap formation; and though usually classed among volcanic productions, in some situations it evidently is of aquatic origin. It is found in the Lipari islands, in Hungary, Iceland, and on the banks of the Rhine; and is used for polishing stones, metals, glass, and ivory; and also for preparing parchment.

Seventh Species. Felspar

Is divided into four sub-species; compact felspar, common felspar, adularia, and Labradore stone.

Eighth Species. Pure Clay.

Is snow white, with occasionally a yellowish tinge, and occurs in kidney-shaped pieces, which have no lustre. It is opaque, soils very little, adheres slightly to the tongue, is light, and intermediate between soft and friable.

Pure clay is found immediately under the soil, accompanied with foliated gypsum and selenite, at Halle, in Saxony, only.

Ninth Species. Porcelain Earth.

The colour is generally a reddish-white, of various degrees of intensity. It occurs massive and disseminated; its particles are fine and dusty, slightly cohering, and feeling fine and light.

It is found in beds in gneiss, accompanied with quartz and other substances, in Saxony, at Passau, Limoges, and in Cornwall. In China and Japan, where it is called kaolin, it is very abundant. It forms the basis of china ware.

Tenth Species. Common Clay.

This is divided into six sub-species, as follow:

1. Loam, of a yellowish-grey colour, frequently spotted with yellow and brown, and occurring massive. It is dull and weakly glimmering, colours a little, adheres pretty strongly to the tongue, and feels slightly greasy. It is often mixed with sand, gravel, and iron ochre.

2. Potter's clay is of two kinds, earthy and slaty. The earthy is of a yellowish and greyish-white colour in general; occurs massive; is opaque, colours a little, feels somewhat greasy, and adheres strongly to the tongue. Slaty potter's clay is generally of a dark ash-grey colour, and feels more greasy than the preceding. It occurs in great rock masses, and in alluvial land. Both kinds are universally distributed, and are of great importance in the arts and in domestic economy.

3. Pipe clay is greyish-white, passing into yellowish-white, occurring massive, of a glimmering lustre, and having its particles pretty coherent. It feels rather greasy, is easily frangible, and adheres pretty strongly to the tongue.

4. Variegated clay is commonly white, red, and yellow, striped, veined, and spotted. It occurs massive, is soft, passing into friable, feels a little greasy, and adheres somewhat to the tongue. It is found in Upper Lusatia.

5. Clay-stone is commonly grey or red, with various intermediate tints. It occurs massive, is dull, opaque, soft, pretty easily frangible, feels rather meagre, and does not adhere to the tongue. It forms vast rock masses, occurs in beds and veins, and is found in Saxony, in Scotland, and in Shetland.

6. Slate clay is of a grey colour, presenting several varieties. It is massive, internally dull, opaque, pretty soft, mild, easily frangible, adheres a little to the tongue, and feels meagre. It is generally found wherever the oval, floetz trap, and alluvial formations occur.

Eleventh species. Polier, or polishing-stone,

Is of a yellowish-grey colour, striped, and the colours alternate in layers. It occurs massive, is dull, very soft, adheres to the tongue, feels fine but meagre, and is nearly swimming. It is found in the vicinity of pseudo-volcanoes, though hitherto it has only been discovered in Bohemia.

Twelfth species. Tripoli

Is of a yellowish-grey colour, passing into ash-grey; occurs massive, is internally dull, very soft, feels meagre and rough, does not adhere to the tongue, and is rather light. It is found in veins and beds in floetz rocks in Saxony, in Derbyshire, and many other countries besides Tripoli, from whence it was first brought. Its use in polishing metals and minerals is well known.

Thirteenth species. Alum-stone

Is of a greyish-white colour, occurs massive, shews a tendency to crystallization, is soft, passing to friable, and light. It is found at Tolfa, near Rome, from whence the famous Roman alum is manufactured.

Fourteenth species. Alum-earth.

The colour is a blackish-brown, and brownish-black; it is massive, dull, feels a little meagre, and somewhat greasy; is intermediate between soft and friable, and light. It is found in beds of great magnitude in alluvial land, and in floetz trap formation in several parts of Germany, in Naples, and in France. It is lixiviated to obtain the alum it contains.

Fifteenth species. Alum-slate

Is divided into two sub-species, as follow:

1. Common alum-slate is between a greyish and blueish-black colour, occurs massive, and in balls, is soft, not very brittle, easily frangible, and not very heavy.

2. Glossy alum-slate is of an intermediate colour, between blueish and iron-black; occurs massive, with a shining semi-metallic lustre, and in other respects resembles the former. It is found in beds and strata in Saxony, France, Scotland, and Hungary; and affords considerable quantities of alum.

Sixteenth species. Bituminous shale

Is of a brownish-black colour, and occurs massive. Internally, its lustre is glimmering; it is very soft, rather mild, feels rather greasy, is easily frangible, and not particularly heavy.

It is found with clay-slate in the coal formation, in Bohemia, England, Scotland, and other coal countries.

Seventeenth species. Drawing slate, or black chalk.

Its colour is a greyish-black, with a tinge of blue; it occurs massive, is opaque, colours and writes, is soft, mild, easily frangible, feels meagre but fine, and is rather light.

It is found in primitive mountains in France, Germany, Iceland, Scotland, and the Hebrides. When of a middling degree of hardness, it is used for drawing.

Eighteenth species. Whet-slate.

The common colour is greenish-grey; it is massive; internally, weakly glimmering, semi-hard, feels rather greasy, and is not particularly brittle or heavy. It occurs in primitive mountains in Saxony, Bohemia, and the Levant. When cut and polished, it is used for sharpening knives and tools.

Nineteenth species. Clay-slate.

Its principal colour is grey, of which there are many varieties. It occurs massive; internally its colour is glistening, the substance opaque, soft, pretty easily frangible. It is found in vast strata in primitive and transition mountains in many different countries, but particularly in Scotland. When split into thin and firm tables, it is used for roofing houses, and other purposes.

Twentieth species. Lepidolite.

Its colour is a kind of peach-blossom, red, verging on lilac-blue, and occurs massive. Its internal lustre is glistening; it is translucent, soft, easily frangible, and easily melts before the blowpipe. Hitherto it has only been found in Moravia, where it lies in gneiss.

Twenty-first species. Mica, or Glimmer.

Its common colour is grey, of great variety of shades. It occurs massive, disseminated in thin tables and layers in other stones, and crystallized either in equilateral six-sided tables, or in six-sided prisms. The surface of the crystals is splendent; internally, shining and splendent. In thin plates, it is transparent; but in larger masses only translucent on the edges. It is semi-hard, feels smooth but not greasy, elastically flexible, and more or less easily frangible.

It forms one of the constituent parts of granite, gneiss, and mica slate, and is almost peculiar to the primitive mountains. It was formerly used instead of glass, for windows and lanterns.

Twenty-second species. Pot-stone.

Its colour is a greenish-grey, of different degrees of intensity; is massive; lustre, internally, glistening and pearly, translucent on the edges; soft, feels greasy, and is very difficultly frangible.

It occurs in beds, or is indular; and is found in the country of the Grisons, in Saxony, and probably in Hudson's-bay, and is nearly allied to indurated talc.

Twenty-third species. Chlorite,

Which see.

Twenty-fourth species. Hornblende,

Which see.

Twenty-fifth species. Basalt.

The usual colour is greyish-black, of various degrees of intensity. It occurs massive in blunt and rolled pieces, and sometimes vesicular. Internally, it is commonly dull. It is usually found in distinct concretions, which are generally columnar, and sometimes upwards of 100 feet in length. Commonly opaque, semi-hard, brittle, very difficultly frangible, melts without addition, and is almost exclusively confined to the floetz trap formation. It occurs in strata, beds, and veins, in almost every quarter of the globe, and is very abundant in Scotland, Ireland, and in other parts of the British European dominions. It is useful for building, as a touch-stone, as a flux, and in glass manufactures.

Twenty-sixth species. Wacke.

The colour is a greenish-grey, of various degrees of intensity. It occurs massive and vesicular, is dull, somewhat glimmering, opaque, usually soft, more or less easily frangible, and not particularly heavy.

It is said to belong exclusively to the floetz trap formation, where it occurs in beds and above clay, and also in veins. It is found in Saxony, Bohemia, and Sweden.

Twenty-seventh species. Clink-stone

Is commonly of a dark greenish-grey colour, always massive, and occurring in irregular columns, and tabular distinct concretions. It is usually translucent on the edges, brittle, easily frangible, and when struck with a hammer sounds like a piece of metal.

It is said to belong to the floetz trap formation, and generally rests on basalt. It is found in Lusatia, Bohemia, South America, and in the isle of Lambash, in the frith of Clyde.

Twenty-eighth species. Lava

Is divided into two sub-species:

1. Slag lava is of a greyish-black colour, passing into other shades. Externally it is spotted, occurs vesicular and knotty, is generally opaque, semi-hard, brittle, easily frangible, and not particularly heavy.

2. Foam lava is of a dark greenish-grey colour, occurs small and fine, vesicular; externally, glimmering, slightly translucent on the edges, brittle, easily frangible, and light. It has often been confounded with pumice-stone, from which, however, it differs very much. On account of its lightness, it is used with advantage in arching vaults and other kinds of building.

Twenty-ninth species. Green Earth.

Its colour is a celaden green, of various degrees of intensity. It occurs massive, in angular and globular pieces, and also disseminated. Internally, it is dull, streak glistening, very soft, easily frangible, and light.

It is principally found in amygdaloid, in Saxony, Bohemia, Scotland, and other places, and is used by painters.

Thirtieth species. Lithomarge

Is divided into two sub-species.

1. Friable lithomarge, or rockmarrow, is snow-white, or yellowish-white, occurs massive, as a crust, and disseminated; is generally coherent, feels greasy, and adheres to the tongue. Is found in tin veins, in Saxony.

2. Indurated lithomarge is most commonly white, of which it presents several varieties; is massive; internally dull; streak shining, very soft, easily frangible, feels greasy, and adheres strongly to the tongue. It occurs in veins of porphyry, &c. in Saxony, Bohemia, Bavaria, &c.

Thirty-first species. Rock Soap

Is of a brownish or pitch-black colour, massive and disseminated, dull, opaque, does not soil, writes like drawing-slate, is easily frangible, and adheres strongly to the tongue.

It is found imbedded in rocks of the floetz trap formation, in Poland, and in the isle of Sky, but is very rare, and found only in small quantities.

Thirty-second species. Yellow Earth.

The colour is ochre-yellow, of different degrees of intensity; it is massive, streak somewhat shining, soils, writes, is very soft, adheres pretty strongly to the tongue, and feels somewhat greasy. It occurs in beds with iron-stone, in Upper Saxony, and is employed as a pigment.

To the clay genus, likewise, belong adhesive slate, float-stone, pinite, and umber, which may be considered as recent discoveries.

FIFTH GENUS.

TALC *Genus.*

First Species. Bole.

Its colour is cream-yellow, passing into various other shades; is commonly massive, very soft, easily frangible, feels greasy, gives a shining streak, adheres to the tongue, and is light. It occurs in rocks belonging to the newest floetz trap formation, and is found in beds of wacke or basalt, in Silesia, Italy, &c. It was formerly employed in medicine, but is now used only as a pigment.

Second species. Native Talc Earth.

The colour is yellowish-grey, passing into cream-yellow. It occurs massive, tuberose, and of other shapes; is internally dull, almost opaque, soft, frangible without much difficulty, and adheres a little to the tongue.

It is found in beds of serpentine, but only hitherto in Moravia.

Third species. Meerschaum.

The usual colour is yellowish-white. It occurs massive, is internally dull, opaque, streak shining, is soft, adheres strongly to the tongue, feels a little greasy, and is nearly swimming. It is principally found in Natolia, in Samos, Hungary, Moravia, Spain, and America. It is much used in the manufacture of heads of tobacco-pipes. It is said that the Turks eat it as a medicine.

Fourth species. Fuller's Earth.

The colours are greenish-white, grey, olive, and oil-green. It is massive; internally dull, usually opaque, gives a shining streak, is very soft, feels greasy, and is not particularly heavy.

It is found in different situations in England, Saxony, Alsace, and Sweden; and is of essential use in cleansing woollen cloth, from which property it receives its name.

Fifth species. Neaphrite,

Which see.

Sixth species. Steatite.

The principal colour is white, of which it presents many varieties. It occurs massive, disseminated, in crusts, and crystallized in six-sided prisms. Internally it is dull, streak shining, very soft, rather difficultly frangible, and feels greasy.

It is found in beds and veins in serpentine in Norway, Sweden, Saxony, England, Scotland, and China. It is used in the manufacture of porcelain, and for other purposes.

Seventh species. Serpentine,

Which see.

Eighth species. Schiller-stone.

Its colour is olive-green, usually disseminated and massive; lustre shining, is soft, slightly brittle, and easily frangible. It occurs imbedded in serpentine, and is found in the Harz, in Saxony, Cornwall, and Ayrshire. It is often confounded with Labradore hornblende.

Ninth species. Talc.

This is divided into three sub-species.

1. Earthy talc is of an intermediate colour between greenish-white and light greenish-grey; friable, strongly glimmering, soils a little, feels rather greasy, and occurs in tin veins near Freyberg in Saxony.

2. Common or Venetian talc is principally of an apple-green colour, massive and disseminated, and in delicate and small tabular crystals. It is almost always splendent and shining, translucent, in thin leaves transparent, flexible, but not elastic; soft, easily frangible, feels very greasy, and approaches to light.

It is almost wholly confined to the primitive mountains, where it is found imbedded in serpentine, and also in veins. It is found in the Tyrolese Alps, in Switzerland, and in Saxony.

3. Indurated talc is of a greenish-grey colour, of various degrees of intensity, occurs massive, is shining, passing to glistening, strongly translucent on the edges, soft, feels rather greasy, and is frangible without particular difficulty. It is found in primitive mountains in Tyrol, Austria, Scotland, and the Shetland isles.

Tenth species. Asbest.

See Asbestos.

Eleventh species. Cyanite,

Which see.

Twelfth species. Actynolite

Is divided into the following sub-species:

1. Asbestous actynolite is of a greenish-grey colour, occurs massive, disseminated, and in capillary crystals; is internally glistening, translucent on the edges, soft, brittle, not easily frangible, nor particularly heavy. It is found in mineral beds in Saxony, and other parts of Germany.

2. Common actynolite is generally of a green leak-colour, passing into other shades of the same; it occurs massive, and likewise crystallized in very oblique six-sided prisms, is splendent externally, semi-hard, rather brittle, and not easily frangible. It is found in beds in primitive mountains, in Saxony, Switzerland, Norway, and Scotland.

3. Glassy actynolite is principally of a mountain-green colour, of various degrees of intensity; occurs massive, or in thin six-sided acicular crystals, is shining and vitreous, strongly translucent, brittle, easily frangible, semi-hard, and is found in similar situations with the preceding.

Thirteenth species. Tremolite.

This is divided into the following sub-species:

1. Asbestous tremolite is of a whitish colour with a tinge of yellow, grey, red, or green: it occurs massive, and in capillary and acicular crystals; internally glistening, very soft, easily frangible, and translucent on the edges.

2. Common tremolite is nearly of the same colour as the preceding, occurs massive, and in long and very oblique four-sided prisms: internally, is shining and glistening, translucent and semi-transparent, semi-hard, and pretty easily frangible.

3. Glassy tremolite is yellowish, reddish, greyish, and greenish-white; occurs massive, and crystallized. Internally, is shining and pearly; is composed of very thin prismatic concretions, which are again collected into very thick prismatic concretions. It is translucent, brittle, and pretty easily frangible, and is said to emit a phosphoric light when rubbed in the dark.

Tremolite is principally found imbedded in primitive mountains, particularly the mountains of Tremola, in Switzerland. It is also found in different parts of Germany, and in Scotland.

Sahlite, lately discovered in Sweden, likewise belongs to the talc genus.

SIXTH GENUS.

Calc *Genus.*

First species. Rock Milk.

Its colour is yellowish white; it is composed of dully, dusty particles generally weakly cohering, feels meagre yet fine, soils very much, and is very light. It is found in fissures and holes of mountains composed of floetz lime-stone, in Switzerland.

Second species. Chalk.

Its colour is principally all yellowish-white: it occurs massive, disseminated, and as crust over flint. Internally, is dull, opaque, soils, writes, soft, sometimes very soft, very easily frangible, feels meagre, and rather rough; effervesces strongly with acids, and is found principally on the sea-coast, though the Chiltern range in England is wholly composed of it. It is used for polishing and cleansing metals, glass, &c. and in some places as a manure, and cement in building.

Third species. Lime-stone

Is divided into several sub-species:

1. Compact lime-stone is of two varieties, common compact lime-stone, and roe-stone. The former is generally of a grey colour, but is frequently veined, zoned, striped, or clouded; occurs massive, and in rolled pieces; is translucent on the edges, semi-hard, brittle, pretty easily frangible; is almost entirely confined, like lime in general, to the floetz mountains; occurs in sand, stone, and coal formations, in England, Scotland, and many other countries; and is frequently used for building or making roads, or when burnt, for manure and cement.

The latter, or roe-stone, is of a chesnut-brown colour, is massive; internally dull, composed of small and fine-grained globular distinct concretions; semi-hard, brittle, not very easily frangible; occurs in beds in considerable quantities in Saxony, and is solely used for manure, for which its admixture with marle admirably fits it.

2. Foliated lime-stone is likewise of two kinds, granular lime-stone, and calc spar. The former is commonly whitish, but presents many varieties of that colour; is massive, occurs almost always in granular distinct concretions, is more or less translucent, semi-hard, brittle, easily frangible, is peculiar to the primitive and transitive mountains, and is chiefly found in Italy, whence it is distributed over Europe, for the purpose of statuary. The white marble of Paros, or granular lime-stone, has long been celebrated. Scotland furnishes some beautiful varieties of marbles, whose uses are well known.

The latter, or calc spar, is principally white, but has many shades. It occurs massive, disseminated, and crystallized, either in six-sided prisms or three-sided prisms. The lustre alternates from splendent to shining and glistening, and is most commonly vitreous. The massive varieties are translucent, and sometimes even transparent. It is found venigenous in almost every rock from granite to the newest floetz trap, occurs in a great variety of mineral veins, and is very universally disseminated, but is found particularly beautiful in Derbyshire, in Ireland, Saxony, France, and Spain.

3. Fibrous lime-stone, is of two varieties, common fibrous lime-stone, and fibrous lime-stone, or calc sinter. The former is commonly greyish, reddish, or yellowish-white; massive, lustre glistening, fragments splintery, more or less translucent, semi-hard, and occurs only in small veins.

The latter, or calc sinter, is principally white, of which it exhibits several beautiful varieties; occurs massive, and also in many particular external forms; internally is glimmering and pearly. It is commonly found in curved lamellar distinct concretions, is more or less translucent, semi-hard, brittle, and easily frangible; it is discovered in almost every lime-stone country. The grotto of Antiparos, and similar situations, afford striking instances of calc sinter. It is the alabaster of the ancients, and is still used in statuary.

4. Pea-stone is commonly yellowish-white, massive, internally dull, opaque or translucent on the edges; soft, very easily frangible; and is found in great masses in the vicinity of the hot springs at Carlsbad in Bohemia. It is composed of spherically round distinct concretions. All the varieties of lime-stone effervesce with acids.

Fourth species. Schâum, or foaming earth,

Is principally of a light yellowish colour; occurs massive and disseminated; is intermediate between shining and glistening; presents large, coarse, small, and fine-grained distinct concretions; is generally opaque, soft, completely friable; feels fine, but not greasy, and cracks a little. It is found in cavities of the oldest floetz lime-stone in Thuringia, and in the north of Ireland.

Fifth species. Slate spar.

Its colour milky, and greenish or reddish-white; occurs massive; lustre intermediate between shining and glistening, and completely pearly; fragments slaty, translucent, soft, and pretty easily frangible. It is found in lime-stone beds in primitive mountains, and is produced in Norway, Saxony, and Cornwall.

Sixth species. Brown spar.

This is divided into the following sub-species:

1. Foliated brown spar, is principally white and red, with several varieties of each. It occurs massive, globular, with tabular impressions, and frequently crystallized, externally shining, internally alternating from shining to splendent. It is found in granular distinct concretions of all magnitudes; is more or less translucent, semi-hard; a little difficultly frangible, and occurs in veins generally accompanied with calc spar, &c. in the mines of Norway, France, Germany, England, and other countries.

2. Fibrous brown spar is of a flesh-red, passing into rose-red; occurs massive, lustre glistening, fragments splintery, in other respects resembling the preceding. Hitherto it has been found only in Hungary and Transylvania.

Seventh species. Rhomb spar.

Its colours are yellowish and greyish-white, occurs only in regular middle-sized rhombs; lustre splendent, generally intermediate between translucent and semi-transparent; is semi-hard, brittle, easily frangible, and is found imbedded in rocks belonging to the talc genus in Switzerland, Sweden, and on the banks of the Loch-lomond in Scotland.

Eighth species. Schaal-stone.

The most common colour is greyish-white; it occurs massive, is shining and nearly pearly, translucent, pretty hard, brittle, easily frangible, and has been hitherto found only in the Bannat of Tameswar, accompanied by copper ore.

Ninth species. Stink-stone.

Its colour is wood-brown, passing into various other shades. It occurs massive, and sometimes disseminated through gyps, is dull or glimmering internally, translucent on the edges, rather soft, easily frangible, and when rubbed, emits an urinous smell. It is found in considerable quantities in the district of Mansfield in Thuringia.

Tenth species. Marle,

Which see.

Eleventh species. Bituminous marle slate.

Its colour is intermediate between greyish and brownish-black; it is massive, from glimmering to shining, fragments slaty, usually soft, not very brittle, easily frangible, and streak shining. It is found in beds along with the oldest floetz lime-stone, and contains much copper intermixed with it, on account of which it is usually smelted in Thuringia.

Twelfth species. Calc tuff.

The colour is yellowish-grey; it is generally perforated or marked with the impressions of other substances, also amorphous, ramose, and corroded. Internally dull, substance opaque, soft, easily frangible, and approaching to swimming. It occurs in alluvial land, and is found in Thuringia, at Gotha, and other places in Germany.

Thirteenth species. Arragone.

The principal colours are greenish-grey, and iron-grey. It occurs crystallized in perfect equiangular six-sided prisms; the lustre is glistening, passing into shining, and is vitreous; it is semi-hard, brittle, not particularly heavy, and plurplur esces a little. It was first discovered in the province of Arragon, whence its name, imbedded in gyps, but has since been found in some other countries of the continent.

Fourteenth species. Appatite.

The usual colours are white, green, blue, and red; it generally occurs crystallized, the radical form of which is the equiangular six-sided prism. Externally it is splendent, internally shining and resinous. It is commonly transparent, semi-hard, brittle, easily frangible, and occurs in tin veins in Saxony, Bohemia, and in Cornwall. It has been confounded with schorl, &c.

Fifteenth species. Asparagus or spargel stone.

The principal colour is asparagus-green; it occurs only crystallized in equiangular six-sided prisms, is internally shining, most frequently translucent, semi-hard, easily frangible, and brittle. Hitherto it has been found only in Murcia in Spain, though supposed to be produced in Norway. It is nearly allied to appatite.

Sixteenth species. Boracite.

Its colours are yellowish, smoke and greyish-white, passing to asparagus-green; it occurs in crystallized cubes, with the edges and angles truncated, internally shining, commonly semi-transparent, semi-hard, brittle, and easily frangible. Hitherto it has been discovered only at Luneburg in Hanover.

Seventeenth species. Fluor,

Which see.

Eighteenth species. Gyps.

This is divided into the following sub-species:

1. Gyps earth is of a yellowish-white colour, passing into some allied shades, is intermediate between fine scaly and dusky, dull and feebly glimmering, soils a little, feels meagre but soft and fine, and is light. It is found, though rarely, in gyps countries, and is formed in the same manner as rock milk. It is used as a manure.

2. Compact gyps, is commonly ash-grey, passing into smoke and yellowish grey, is massive, internally dull, feebly translucent on the edges, very soft, frangible without great difficulty, and is employed in architecture, and sculpture, under the name of alabaster.

3. Foliated gyps is commonly white, grey, or red, presenting spotted, striped, and veined colour delineations. It occurs massive, and in blunt-edged pieces, but seldom in crystals. Internally it alternates from shining and glistening to glimmering, is translucent and duplicating, very soft, and not particularly difficultly frangible. It has been confounded with granular lime-stone.

4. Fibrous gyps is principally white, grey, and red, with various shades of each. It occurs massive and dentiform, the internal lustre is usually glistening and pearly, commonly semi-transparent and translucent, very soft, and easily frangible.

Fossils belonging to the gyps formation occupy different situations. They are found in Switzerland, Thuringia, Derbyshire, Cornwall, Moffat in Scotland, and other places.

Gyps, when burnt, forms an excellent cement, and is used for many ornamental purposes.

Nineteenth species. Selenite.

Its principal colour is snow-white, passing into other neighbouring shades: is generally massive, but not unfrequently crystallized in pretty oblique six-sided prisms, the crystals seldom large, but internally shining and splendent. Fig. 12.

Selenite is completely transparent, soft, somewhat flexible, not very frangible, and is found in the oldest gyps formation, in single crystals in clay beds in the newest formation, and in other situations. It is common in Thuringia, at Montmartre near Paris, Shotover near Oxford, and in the isle of Sheppy. It is employed in taking the most delicate impressions, for crayons and other purposes.

Twentieth species. Cube spar.

The colour is milk-white with various allied shades. It is massive, occurring in large, coarse, and small ground distinct concretions. The lustre is shining, passing into splendent, translucent, softish, very easily frangible, and not particularly heavy. It is found in salt rocks in Salzbourg.

To the calc genus are also referred phosphorite, which forms a great bed in Estremadura in Spain; and the anhydrite, found in the duchy of Wirtemberg.

SEVENTH GENUS.

BARYTE *Genus.*

First species. Witherite.

Is commonly of a light yellowish-grey colour generally massive, but sometimes crystallized in six-sided prisms, or double six-sided pyramids. The lustre of the principal fracture is shining; the fragments generally wedge-shaped. It is translucent, somewhat semi-hard, brittle, easily frangible, and pretty heavy. Fig. 13.

It melts, without addition, before the blowpipe, into a white enamel, and occurs in veins along with heavy spar, lead-glance, &c. at Anglesark in Lancashire. Combined with muriatic acid it may be used in medicine, though a very active poison of itself.

Second species. Heavy spar or baryte.

See BARYTES.

EIGHTH GENUS.

STRONTIAN *Genus.*

First species: Strontian.

The usual colour is intermediate between asparagus and apple-green; it occurs most commonly massive, but sometimes crystallized in a circular six-sided prism. The crystals are scopiformly and manipularly aggregated. The lustre of the principal fracture is shining, of the cross fracture glistening. It is translucent in a greater or less degree, soft, and semi-hard, brittle, easily frangible, dissolves in acids with effervescence, and occurs along with lead-glance, heavy spar, &c. at Strontian in Argyleshire, the only place where it has yet been found.

Second species. Celestine

Is divided into two sub-species:

1. Fibrous celestine, is of an intermediate colour, between indigo-blue and blueish-grey; it occurs massive and in plates, and also crystallized, showing a tendency to prismatic distinct concretions; is translucent, soft or semi-hard, easily frangible, and pretty heavy. It is found in Pennsylvania and in France.

2. Foliated celestine, is of a milky-white colour, falling into blue; it occurs massive, and also crystallized in six-sided tables intersecting each other. It has a glistening lustre, is strongly translucent, softish, not particularly brittle, easily frangible, and hard. It occurs sometimes in sulphur beds, and is

found very finely crystallized in Sicily, and likewise near Bristol.

CLASS II.

FOSSIL SALTS.

The substances included in this class are confined to those which are found in a natural state only; and the greater part of them appear to be formed by the agency of water, air, &c.

The distinguishing characters of fossil salts are, their taste and easy solution. They resemble each other so closely, that the term saline consistence is used to express whatever relates to hardness, tenacity, and frangibility.

First species. Natron, or natural soda.

It may be divided into the two following sub-species:

1. Common natron, is of a yellowish or greyish-white colour, occurs in fine flakes or in dusty particles, has a sharp alkaline taste, effervesces with nitric acid, is easily soluble in water, and strikes blue vegetable tinctures green. It occurs as an efflorescence in the surface of soil, or on the sides and bottoms of lakes that occasionally become dry. It is found in very large quantities in Hungary, Bohemia, and Egypt, and in many other countries of the Old World.

2. Radiated natron, or natural soda, is of a greyish or yellowish-white colour, occurs in crusts or crystallized in capillary or acicular crystals, is glistening and translucent, and is found in large quantities in the province of Sukana in Barbary, and in Southern Africa.

Natron is principally employed in the manufacture of glass, soap, and for washing. It is also used as a flux after being purified.

Second species. Natural nitre.

The colour is greyish or yellowish-white, approaching to snow-white; it is flaky, sometimes verges to solid and massive, is of a saline consistence, and tastes saltly cooling. Placed on hot iron, it hisses and detonates; is usually found in thin crusts on the surface of the soil at particular seasons of the year, particularly in hot climates. It is also met with in various countries of Europe, and is much used in making gunpowder, in medicine, and the arts. The greatest part, however, employed for those purposes, is an artificial preparation from the refuse of animal and vegetable bodies undergoing putrefaction, and mixed with calcareous and other earth.

Third species. Natural Rock-salt

Is divided into two sub-species:

1. Rock or stone-salt, which is of two kinds, foliated and fibrous. The former is commonly of a white or grey colour, occurs massive and disseminated, and also crystallized in cubes; in general is strongly translucent, rather hard, easily frangible, and feels somewhat greasy. The latter is greyish, yellowish, and snow-white; occurs massive, is strongly translucent, verging to semi-transparent, decrepitates when laid on burning coals, and is found in beds lying over the first or oldest floetz trap formation. It forms whole hills at Cordova in Spain, is found also in Germany, and almost every country in the world. At Nantwich in Cheshire it has long been dug. Its use is as general as its dissemination. It is employed as a daily seasoning for our food, as a manure, in various manufactures, and for purposes too numerous to mention.

2. Lake-salt occurs either in thin plates, which are formed on the surface of salt-lakes, or in grains at their bottom. It is translucent, and of a saline consistence. It is found in Cyprus, near the Caspian Sea, and in various parts of Africa.

Fourth species. Natural sal ammoniac.

The colour is commonly greyish or yellowish-white. It is of a saline consistence, and is flaky, with an urinous taste. It is sometimes found massive, stalactitic, tuberose, botryoidal, and crystallized. It is the product of volcanoes and pseudo-volcanoes, and is found in Italy, Sicily, in the vicinity of inflamed beds of coal both in England and Scotland, and in several countries of Asia.

Fifth species. Natural Epsom salt.

Colour a greyish-white. It occurs in capillary efflorescences, and is mealy or flaky, of a saline consistence, and taste saltly bitter. It is found as an efflorescence, on clayey stones or gyps rocks, at Sena, at Solsatara, in Hungary and Bohemia. It is also contained in many mineral springs, particularly those of Epsom, whence it derives its name. Epsom salts are much used as an easy purgative. Considerable quantities of magnesia may be obtained from them.

Sixth species. Natural Glauber salt.

The colour is usually greyish and yellowish-white. It occurs in the form of mealy efflorescences, in crusts, and sometimes crystallized in acicular and in six-sided prismatic crystals. Internally it is shining, with a vitreous lustre, is soft, brittle, easily frangible, and has a cooling but a saltly bitter taste.

It is found on the borders of salt-lakes, on moorish ground, on old and new-built walls in different countries of Europe, Asia, and Africa, and is used as a purgative medicine, and in some places as a substitute for soda in the manufacture of white glass.

Seventh species. Natural alum

Is of a yellowish or greyish-white colour; occurs as a mealy efflorescence, or in delicate capillary crystals; has a sweetish astringent taste, and is produced in various situations in Scotland, Germany, Italy, Spain, Sweden, and in Egypt.

Alum is employed as a mordant in dyeing, in the manufacture of leather, as a medicine, for preventing wood from catching fire, and for preserving animal substances from putrefaction.

Eighth species. Hair salt.

The principal colours are snow, yellowish, and greyish-white. It occurs in delicate capillary crystals; has a saline consistence, and a sweetish astringent taste.

Hair salt is found in different mine countries on the continent, at Whitehaven in England, and near Paisley in Scotland, and bears a striking resemblance to fibrous gyps.

Ninth species. Rock butter.

The colour is light-yellow or greyish-white. It occurs massive and tuberose, is translucent, has a saline consistence, or sweetish-sour astringent taste, and feels a little greasy. It oozes out of fissures of rocks of alum slate, and is found in Lusatia, Thuringia, Denmark, Siberia, and near Paisley in Scotland.

Tenth species. Natural vitriol

Is divided into the three following sub-species:

1. Iron vitriol, is commonly of an emerald and

verdigris green. It occurs massive, tuberose, stalactitic, and crystallized in different figures; is splendent and vitreous, has a saline consistence, and a sourish astringent taste. It is found usually along with iron pyrites, by the decomposition of which it is formed, in different countries of continental Europe, in many of the English mines, and in America. It is employed to dye linen yellow, and wool and silk black, in the preparation of ink, as a paint, &c.

2. Copper vitriol, is usually of a dark sky-blue colour. It occurs massive, disseminated, stalactitic, dentiform, and crystallized; is translucent, soft, very brittle, and has a styptic taste. It is found in various mining countries, in Wicklow, and in Anglesea. It is used in cotton and linen printing, and when prepared is employed by painters.

3. Zinc vitriol, is of a greyish, yellowish, reddish, and greenish-white colour. It occurs tuberose, stalactitic, and coralloidal, is translucent, of a saline consistence, and a styptic taste. It is produced most abundantly where much blende occurs, and is found in Austria, Hungary, and Sweden.

Here it must be remarked, that borax, though so well known by name, is without a place in the Wernerian system, as it is uncertain whether or no it occurs in a solid state. It is most probable that it occurs only in solution in certain lakes. See BORAX.

The new genus stallite, of which only one species, cryolite, has been found in Greenland, seems properly to come under this head.

CLASS III.

INFLAMMABLE FOSSILS.

Fossils belonging to this class are light, brittle, mostly opaque, yellow, brown, or black, seldom crystallized, and never feel cold. They are more nearly allied to the metallic than to the earthy or saline classes.

FIRST GENUS.

SULPHUR *Genus.*

First species. Natural sulphur.

It contains the two following sub-species:

1. Common natural sulphur, is of the colour the name expresses, but of different degrees of intensity. It occurs massive, disseminated, and crystallized in octahedrons or double six-sided pyramids, is internally between shining and glistening, translucent, in crystals frequently transparent, very soft, easily frangible, and light.

It is found in masses in gyps, in veins that traverse primitive rocks, in nests of limestone, and in other situations, and is produced in every quarter of the world, though in the British dominions it seems to be confined to Ireland.

2. Volcanic natural sulphur is of the colour the name imports, but with a considerable tinge of green. It occurs corroded, vesicular, perforated, amorphous, and sometimes as a sublimate in flowers, is glistening and resinous, and translucent in a slight degree. It is found only in volcanic countries, and among lava, but is produced in great abundance; and is employed in medicine, in the composition of gunpowder, and as a vapour in whitening wool and silk.

SECOND GENUS.

BITUMINOUS *Genus.* See BITUMEN.

First species. Brown coal. See COAL.

FOURTH GENUS.

GRAPHITE *Genus.*

First species. Glance coal.

This is divided into two sub-species:

1. Conchoidal glance coal, is of an iron-black colour, of different degrees of intensity, occurs massive and vesicular, internally shining, bordering sometimes on semihard, brittle, easily frangible, and light. It burns without flame or smell, and has hitherto been found only in the newest floetz mass formation, accompanied with other kinds of coal, at Meissner in Hessia. The fracture is conchoidal.

2. Slaty glance coal, is of a dark iron black colour, occurs massive, is shining and glistening, soft, very easily frangible, light, and intermediate between sectile and brittle. It is found imbedded in masses, beds, and veins, in primitive, transitive, and floetz rocks, and is produced in Spain, Savoy, Saxony, Bohemia, and in the isle of Arran in Scotland. Its principal fracture is more or less slaty.

Second species. Graphite.

This contains two sub-species:

1. Scaly graphite, is commonly of a dark steel-grey colour. It occurs massive and disseminated, is usually glistening, fracture scaly-foliated, is very soft, perfectly sectile, writes and soils, feels very greasy, and is rather difficultly frangible.

2. Compact graphite, is rather blacker than the preceding, is internally glimmering with a metallic lustre, fracture fine-grained, in other respects agreeing with the preceding. It usually occurs in beds, and is found near Keswick in England, in Ayrshire in Scotland, and in various other parts of Europe, Asia, and Africa. The finer kinds are first boiled in oil, and then cut into pencils. The coarser parts and sawings are melted with sulphur, and then cast into coarse pencils for the use of artificers. It is likewise applied to various other purposes, under the vulgar name of black lead.

Third species. Mineral charcoal.

The colour is a greyish-black. It occurs in small angular and somewhat cubical-shaped pieces, is glimmering, with a silky lustre, soils strongly, is soft, and light. It is found in thin layers in different kinds of coal, and is widely disseminated.

FIFTH GENUS.

RESIN *Genus.* See RESINS.

First species. Amber.

This is divided into the two following sub-species:

1. White amber, is of a straw-yellowish colour. It occurs massive, and sometimes associated with the following sub-species, is glistening with a resinous lustre, fracture conchoidal, and simply translucent.

2. Yellow amber, is of a wax-yellow colour, passing into several neighbouring shades. It occurs always in indeterminately angular blunt-edged pieces, is externally dull, internally splendent, with a vitreous and resinous lustre. It is transparent, soft, rather brittle, pretty easily frangible, light, and swimming. It burns with a yellow-coloured flame, emitting an agreeable odour; when rubbed, it acquires a strong negative electrical virtue; is found in layers of bituminous wood, and in moor coal, on sandy sea-

shores, and frequently floating on the sea. It is chiefly produced on the coasts of Prussia, in Sweden, Norway, &c. and according to some has been found in the alluvial land near London. It admits of a fine polish, and is cut into necklaces, bracelets, snuff-boxes, and various other articles. The oil and acid obtained from it are used in medicine.

Second species. Honey-stone.

See Mellites.

CLASS IV.

METALLIC FOSSILS.

First genus. *Platina.*

First species. Native platina.

The colour is very light steel-grey, approaching to silver-white. It occurs in flat, smooth, and smallish grains, externally shining, lustre metallic, intermediate between semihard and soft, completely malleable, pretty flexible, and very heavy, its specific gravity being about 15.6.

Platina is the least fusible of metals, and does not amalgamate with mercury. It has hitherto been found only in sand accompanied with other metals, and is produced in South America, and probably also in St. Domingo and Barbadoes. From the peculiar qualities it possesses of resisting the action of many salts, of remaining unaltered in the air, and of receiving a fine polish, it has been rendered subservient to several purposes in chemistry and the arts. See Platinum.

SECOND GENUS. *Gold.*

First species. Native Gold.

This is divided into three sub-species:

1. Gold-yellow native gold, is of a perfect colour, corresponding to its name. It seldom occurs massive, often disseminated in membranes, in roundish and flattish pieces, in grains, and also crystallized in cubes, octahedrons, simple three-sided pyramids, garnet dodecahedrons, and acute double eight-sided pyramids. External lustre of the crystals is splendent; internally it is glimmering, passing into glistening. It is soft, completely malleable, flexible, and uncommonly heavy. It is found in veins, beds, disseminated in rocks, and in grains, in almost every country of the world, but commonly in too small quantities to be collected for use. America and Africa supply the largest quantities.

2. Brass-yellow native gold, is principally of the colour of brass, occurs disseminated, capillary, moss-like, reticulated, and in leaves, also crystallized in thin six-sided cubes, and is rather lighter than the preceding. It is found in different situations in Bohemia, Transylvania, and Norway.

3. Greyish-yellow native gold, is of a brass-yellow colour falling into steel-grey, occurs in very small flattish grains like platina, and is found with that metal. See Aurum.

THIRD GENUS. *Mercury.* See Hydrargyrum.

First species. Native mercury, or quicksilver.

The colour is tin-white: it occurs perfectly fluid in globules, is splendent, and has a metallic lustre, does not wet, feels very cold, and is uncommonly heavy. Before the blowpipe it is volatilized, without any smell. It is usually found in cinnabar at Idria. It occurs in a compact limestone, and here it is very abundant. It is likewise produced in different parts of Germany, France, Spain, and in very large quantities in Peru.

The uses of quicksilver are multifarious, and cannot be enumerated in this place.

Second species. Natural amalgam.

Fluid, or semi-fluid amalgam, is of an intermediate colour between tin and silver-white. It occurs in small massive pieces, and in balls, also disseminated and crystallized in different forms. Externally it is shining and splendent, is soft and somewhat fluid; when cut or pressed, it emits a creaking sound like natural amalgam, and is uncommonly heavy.

Third species. Mercurial horn-ore, or corneous mercury,

Is of an ash-grey colour of various degrees of intensity; occurs very rarely massive, but commonly in small vesicles, internally crystallized and splendent. It is soft, sectile, easily frangible, and heavy. It is usually found with the other species of mercury, and is produced in the same countries. It was first discovered in the mines of the Palatinate.

Fourth species. Mercurial liver-ore, or mercurial hepatic-ore.

Compact mercurial liver-ore, is of an intermediate colour between dark-red and lead-grey, occurs massive, is glistening and glimmering internally, opaque, soft, sectile, easily frangible, and uncommonly heavy. It is the most common ore of mercury at Friaul in Idria.

Fifth species. Cinnabar.

Dark-red cinnabar, is principally of a perfect cochineal red, occurs massive, disseminated, in blunt-cornered pieces, in membranes, amorphous, dendritic, fruticose, and crystallized. The crystals are small, splendent externally, and shining internally. The massive cinnabar is opaque or translucent on the edges, very soft, sectile, easily frangible, and uncommonly heavy.

Bright-red cinnabar is of a lively scarlet-red colour. It occurs massive and disseminated, is internally glimmering, substance opaque, streak shining, soils, is very soft, sectile, very easily frangible, and very heavy. Both belong to the same countries with quicksilver. In Idria, Spain, and Peru, this genus is most abundant. It does not occur in Norway, Sweden, Great Britain, or Ireland. From the ore of cinnabar the greatest part of the mercury used in commerce is obtained.

FOURTH GENUS. *Silver.*

First species. Native silver.

Common native silver is of the colour the name expresses. It occurs massive, disseminated, in pieces, plates, and membranes, as well as in other forms, besides being crystallized in cubes, octahedrons, four-sided rectangular prisms, double six-sided pyramids, double three-sided pyramids, and hollow four-sided pyramids. It is soft, perfectly malleable, common flexible, and very heavy when pure. It appears to belong to the newer primitive rocks, where it occurs in veins, and is usually accompanied with heavy spar and quartz.

Second species. Antimonial silver.

The colour is intermediate between tin-white and silver-white. It occurs massive, disseminated, and crystallized, is externally glistening, internally shining and splendent, with a metallic lustre. It is found in coarse, small, and fine granular distinct concretions, is sectile, not very difficultly frangible, soft, and uncommonly heavy. It contains upwards of 80 parts of silver. It occurs in veins composed of calx, spar, &c. in Spain, Germany, and other countries.

Third species. Arsenical silver.

The colour is tin-white, passing into silver-white. It occurs massive, disseminated, globular, and crystallized; is softish, sectile, and very heavy. It contains about 12 parts of silver, much arsenic and iron, and is usually found with native arsenic and other minerals in Germany and Spain, but is a rare mineral.

Fourth species. Corneous silver-ore, or horn-ore.

The colour is most frequently a pearl-grey, of all degrees of intensity. It occurs massive, disseminated, in membranes, balls, and also crystallized in cubes and in acicular and capillary crystals. It is more or less translucent, soft, perfectly malleable, and heavy. It contains upwards of 60 parts of silver, and is found always in veins. It is widely distributed over the globe, but it is most abundant in South America. It is sometimes found in Cornwall, and receives its name from cutting like horn.

Fifth species. Silver-black.

The colour is a blueish-black, whence its name. It occurs massive, disseminated, and in various other forms, of all degrees of consistence, from friable to solid. It gives a shining metallic streak, soils very little, is easily frangible, sectile, and heavy. It is found with silver-glance and hornore in Hungary, Bohemia, Norway, and Siberia.

Sixth species. Silver-glance

Is of a dark-blackish lead-grey colour, occurs usually massive, disseminated, in membranes, &c. and also crystallized in cubes, octahedrons, garnet dodecahedrons, and double eight-sided pyramids. Externally it is shining and glistening; internally it alternates from shining to glistening, and has a metallic lustre. It is soft, completely malleable, pretty flexible, and uncommonly heavy, containing upwards of 80 parts of pure silver; and is found in veins, along with native silver and other minerals, in Hungary, Austria, and other countries of Europe, but more particularly in Mexico and Peru.

Seventh species. Brittle silver-glance.

The colour is intermediate between iron-black and dark lead-grey. It occurs massive, disseminated, in membranes, and frequently crystallized in equiangular six-sided prisms, and rectangular four-sided tables. Externally it is highly splendent, internally shining and glistening. It is soft, brittle, easily frangible, and uncommonly heavy, containing upwards of 60 parts of silver. It is found always in veins, accompanied with other minerals, and principally in Hungary and Saxony.

Eighth species. Red silver-ore.

Dark-red silver-ore is intermediate between cochineal red and lead-grey. It occurs massive, disseminated, dendritic, in membranes, and crystallized in equiangular six-sided prisms. It is externally splendent; internally it alternates from shining to glimmering. The massive varieties are opaque; the crystallized passing from semi to transparent. It is soft, sectile, easily frangible, and heavy.

This species occurs always in veins, accompanied with other minerals, and is found in Bohemia, Hungary, Norway, and other countries.

Ninth species. White silver-ore.

The colour is a very light lead-grey. It occurs massive and disseminated, has a metallic lustre, a shining streak, is soft, slightly flexible, easily frangible, and heavy. It contains large quantities of lead, sulphur, and antimony, and scarcely 10 parts of silver. It is always found in veins, and chiefly near Freyberg.

Tenth species. Black silver-ore.

The principal colour is iron-black, inclining to steel-grey. It occurs massive, disseminated, and crytallized in three-sided pyramids. Internally it is shining with a metallic lustre. It is semihard, sectile, easily frangible, and heavy. See ARGENTUM.

FIFTH GENUS, *Copper.* See CUPRUM.

First species. Native copper.

The colour is copper-red, but frequently tarnished. It occurs massive, disseminated, and in various other forms, besides being crystallized in cubes, dodecahedrons, &c. It is intermediate between semihard and soft, completely malleable, common flexible, difficultly frangible, and very heavy. It is usually found in veins and sometimes in beds, and is produced in Cornwall, Anglesea, the Shetland islands, and many other countries of Europe, Asia, and America. Copper may be applied to a vast number of useful purposes, and is next to iron the most necessary of metals.

Second species. Copper-glance.

Compact copper-glance is usually of a dark lead-colour, passing into blackish-grey. It occurs massive, disseminated, in membranes, and occasionally crystallized; externally shining, internally between shining and glistening. It is soft, perfectly sectile, easily frangible, and heavy.

Third species. Variegated copper ore.

Its colour, when dug, is intermediate between copper-red and pinchbeck-brown, but it soon becomes tarnished. It occurs massive, disseminated in plates, membranes, and crystallized in octahedrons. It is soft, slightly sectile, easily frangible, and heavy; and is found in beds, veins, and rocks of different formations, in Cornwall, and various parts of continental Europe. It yields about 70 parts of pure copper.

Fourth species. Copper pyrites.

When fresh, its colour is brass-yellow, of different shades according to its richness. It occurs massive, disseminated in membranes, &c. and also crystallized in various figures. Externally it is intermediate between glistening and shining, internally soft; is between semihard and soft, brittle, easily frangible, and heavy.

Fifth species. White copper ore

Is of an intermediate colour between silver-white and bronze-yellow: occurs massive and disseminated; is internally glistening, with a metallic lustre; rather soft, brittle, easily frangible, and heavy. It is found in veins and mineral beds in primitive mountains, and is produced in Cornwall, in different parts of Germany, in Siberia, and in South America; but it is one of the rarest species of copper ore.

Sixth species. Grey copper ore, or Fahl ore.

The most common colour is steel-grey: it occurs massive, disseminated, and also crystallized in tetrahedrons, octahedrons, and garnet dodecahedrons. It is more or less semihard, brittle, easily frangible, and heavy; and is found in the newer primitive rocks, and likewise in transitive and floetz rocks, in several mines of Cornwall, in Germany, Italy, Sweden, Norway, Siberia, and Chili. It is usually smelted on account of the copper it contains.

Seventh species. Copper black.

The colour is usually intermediate between blueish and brownish-black: it occurs massive, or disseminated, and as a coating, to other ores of copper; is always more or less cohering, and heavy, containing from 40 to 50 parts of copper. It is usually found with copper pyrites, &c. and is produced in Silesia, Germany, France, Sweden, Norway and Siberia. Sometimes it is very beautiful.

Eighth species. Red copper ore.

Compact red copper is usually of a dark cochineal-red colour: occurs massive, in membranes, crowded, amorphous, and also disseminated. Internally it is glimmering, inclining to glistening, with a semimetallic lustre: it is opaque, semihard, brittle, easy frangible, and heavy.

Ninth species. Tile ore.

Earthy tile ore is usually of a red hyacinth colour; massive, disseminated, and incrusting copper pyrites; is intermediate between friable and solid, soils slightly, is almost always coherent, and is heavy. It is found in veins, commonly accompanied with native copper ore and malachite.

Tenth species. Copper azure.

Earthy copper azure is of a smalt-blue colour; usually friable, and disseminated; is composed of dusty particles, does not soil, is chiefly cohering, and approaches to heavy. It is found in small quantities, usually accompanied with malachite and copper green, in different parts of Germany, in Norway, and Siberia.

Eleventh species. Malachite, which see.

Twelfth species. Copper green.

The principal colour is verdigris-green, of different degrees of intensity: it usually occurs massive, disseminated, and coating malachite: is internally shining; more or less translucent, soft, not very brittle, easily frangible, and intermediate between heavy and not particularly heavy. It is found in the same geognostic situation with malachite, in Cornwall and other countries, but is rare.

Thirteenth species. Iron-shot copper green.

Earthy iron-shot copper green is usually of an olive-green colour: occurs massive, and disseminated; is dull, soils a little, soft, passing into friable, not very brittle, easily frangible, and not particularly heavy.

Fourteenth species. Copper emerald.

The colour is an emerald-green. It occurs in crystallized six-sided prisms, which are externally and internally shining, with a vitreous lustre, and translucent. It is semihard, brittle, and not particularly heavy; and is found in the remoter parts of the Russian dominions, and on the Chinese frontiers.

Fifteenth species. Copper mica

Is usually of an emerald-green colour: it occurs massive, disseminated, and occasionally crystallized in very thin six-sided tables. Externally it is smooth and splendent, internally splendent, with a pearly lustre. The massive varieties are translucent; the crystallized transparent. It is soft, sectile, not very brittle, nor particularly heavy; and has hitherto been found only in veins in Cornwall, where it passes under the unscientific name of foliatic arseniat of copper.

Sixteenth species. Lenticular ore.

The colour is sky-blue, sometimes passing into verdigris green. It occurs crystallized in small, flat, double, four-sided pyramids; is externally shining; translucent, soft, rather brittle, and very easily frangible. Hitherto it has been found only in Cornwall.

Seventeenth species. Oliven ore.

Foliated oliven ore is of a perfect olive-green: seldom occurs massive, usually in drusy crusts, and in small crystals, presenting acute rhomboids, and oblique four-sided prisms. Internally it is glistening, with an adamantine lustre. It is very soft, sectile, and heavy in a low degree; and has hitherto been found only in Cornwall.

SIXTH GENUS. *Iron.*

First species. Native iron

Is of a light steel-grey colour, inclining to silver white: it has hitherto been found only ramose; internally it is intermediate between glimmering and glistening, with a perfect metallic lustre, and a hackly fracture. It is between soft and semihard, perfectly malleable, common flexible, difficultly frangible, and uncommonly heavy. Hitherto it has been found only in loose masses on the surface of the earth, and is a rare production.

Second species. Iron pyrites.

Common iron pyrites is usually of a perfect bronze-yellow colour: it occurs massive, disseminated in membranes, and also crystallized in cubes, octahedrons, dodecahedrons, icosahedrons, and leuzite crystals. It is hard, brittle, and heavy, and when rubbed or struck with steel, emits a strong sulphureous smell. It occurs in almost every kind of mineral repository, but most commonly in granite; its geographic distribution is equally extensive, but it is principally valued on account of the sulphur which may be extracted from it by sublimation.

Third species. Magnetic pyrites

Is of an intermediate colour between bronze-yellow and copper-red: it occurs massive and disseminated; is internally shining, with a metallic lustre, passes from hard to semi-hard, is brittle, easily frangible, and heavy. It is attracted by the magnet; is found only in primitive mountains, in Caernarvonshire, in several parts of Germany, in Norway and Siberia; and is used for the same purposes as common pyrites.

Fourth species. Magnetic iron-stone.

Common magnetic iron-stone is of an iron-black colour: is massive, disseminated, and also crystallized in cubes, octahedrons, and garnet dodecahedrons, and rectangular four-sided prisms. It is externally shining; internally between splendent and glistening, with a metallic lustre: is intermediate between hard and semihard, brittle, and heavy. It occurs most frequently in primitive mountains, and is found in the Shetlands, many parts of Germany, and other countries, particularly Sweden. When pure, it affords excellent bar iron.

Fifth species. Iron glance.

Common iron glance is usually of a dark steel-grey colour, with several different shades. It commonly occurs massive and disseminated, and also crystallized in flat, double, three-sided pyramids, and in double three-sided pyramids. Externally it alternates from splendent to glistening; internally it is most commonly glistening. It is hard, brittle, heavy, and rather difficultly frangible. It occurs in beds and veins in primitive and transitive mountains, and is found in considerable quantities in Sweden and other countries, and affords, when smelted, an excellent malleable iron.

Sixth species. Red iron-stone.

Red iron froth. The colour is intermediate between cherry-red and brownish-red. It occurs commonly friable, massive, sometimes coating and disseminated, and is composed of scaly particles, which are glimmering, and have a semi-metallic lustre. It soils strongly, feels greasy, and is pretty heavy. It is found usually in veins, and chiefly in primitive mountains in Lancashire, Cornwall, Norway, Germany, and Chili, and produces good iron.

Seventh species. Brown iron-stone.

Brown iron froth is of an intermediate colour between steel-grey and clove-brown, and is between friable and solid. It occurs massive, coating, spumous, &c. and is composed of scaly particles, shining and glistening, with a metallic lustre. It soils strongly, feels greasy, and is very light. It is commonly found lining drusy cavities, in brown hematite, in the Shetland isles, in various parts of Germany, and in Chili.

Eighth species. Sparry iron-stone.

The principal colour is a light yellowish-grey, which, on exposure to the air or heat, changes into brown or black. It occurs massive, disseminated, with pyramidal impressions, in plates, and crystallized. It is found in granular distinct concretions, commonly translucent on the edges, semihard, not very brittle, easily frangible, and heavy. It is chiefly confined to the primitive and floetz mountains, and is produced in small quantities in England, Scotland, and Ireland; but on the continent it is in some places very abundant, and affords an iron which is excellently adapted for steel-making.

Ninth species. Black iron-stone.

Compact black iron-stone, is of an intermediate colour between blueish-black, and dark steel-grey: it occurs massive, tuberose, reniform, &c. It is semihard, brittle, easily frangible, and heavy.

Tenth species. Clay iron-stone.

Reddle is of a light brownish-red, passing into cherry-red: it occurs only massive; soils strongly, and writes, is sectile, easily frangible, and rather heavy. It is chiefly found in the newer clay-slate, and is produced pretty abundantly in Germany and Siberia. The coarser varieties are used by the carpenter, the finer by the painter, under the name of red-chalk.

Eleventh species. Bog iron-ore.

Morass ore is of a yellow-brown colour, sometimes friable, sometimes coherent, and occurs massive, corroded, in grains, and tuberose. It soils pretty strongly, feels meagre but fine, and is lightish.

Twelfth species. Blue iron-earth.

When fresh it is whitish, but soon becomes of an indigo-blue colour, of different degrees of intensity; it occurs massive, disseminated, and thinly coating; the particles are dull and dusty; it soils slightly, feels fine, and is lightish. It is found in nests in clay-beds, and other situations, in the Shetland isles, Iceland, Sweden, and Siberia.

Thirteenth species. Green iron-earth.

Friable green iron-earth is of a siskin-green colour, occurs massive and disseminated, is more or less cohering, soft, fine, easily frangible, and intermediate between particularly heavy and heavy.

Fourteenth species. Cube ore.

The colour is olive-green, of different degrees of intensity; it occurs massive, and crystallized in small cubes, is translucent, soft, brittle, and not particularly heavy. It is found in veins, but hitherto only in Cornwall. See FERRUM.

SEVENTH GENUS. *Lead.*

First species. Lead glance.

Common lead glance is of a fresh lead-grey colour, of different degrees of intensity; it occurs massive, disseminated, in membranes, &c. and also crystallized in cubes, octahedrons, four-sided prisms, six-sided prisms, and three-sided tables. It is soft, sectile, externally easily frangible, and uncommonly heavy; and is found in veins and beds in primitive, transitive, and floetz mountains, at lead-hills in Lanarkshire, Derbyshire, and several other counties of England, Scotland, and Wales; besides being widely diffused over other parts of the globe. It is most frequently worked as an ore of lead, but sometimes as an ore of silver.

Second species. Blue-lead ore.

Is of an intermediate colour between dark indigo-blue and lead-grey; it occurs massive, and crystallized in perfect six-sided prisms, is soft, sectile, easily frangible, and heavy, and is found in veins with other minerals of the same class, but is altogether a rare fossil, nor has it hitherto been discovered in Britain.

Third species. Brown-lead ore.

Is of a hair-brown colour of different degrees of intensity; it occurs massive, and crystallized in six-sided prisms, is feebly translucent, soft, not very brittle, easily frangible, and intermediate between heavy and uncommonly heavy. It is found in veins, accompanied with other minerals, in Bohemia, Hungary, Brittany, and Saxony.

Fourth species. Black-lead ore.

The colour is greyish-black, of different degrees of intensity; it occurs massive, disseminated, and crystallized in six-sided prisms; externally is usually splendent, internally shining with an adamantine lustre, is rather brittle, easily frangible, and heavy.

It is found in veins, and almost always accompanied with other kinds of lead-ore, at lead-hills in Scotland, Bohemia, Saxony, and other mineral countries.

Fifth species. White-lead ore.

The colour is white, but has various shades; it occurs massive, disseminated, in membranes, but most commonly crystallized in prisms and pyramids, of different figures. Externally, it is specular splendent, internally between splendent and glistening, with an adamantine lustre. It is soft, brittle, very easily frangible, and heavy, and is found in most places where the other species occur, in England, Wales, Scotland, Ireland, &c. Next to lead glance it is the most common of the lead ores, but is seldom in sufficient abundance to become an object to the metallurgist.

Sixth species. Green-lead ore.

Its colour is grass-green, of various shades; it generally occurs crystallized, in six-sided prisms, is always translucent, soft, rather brittle, very easily frangible, and heavy. It is produced in Scotland and other countries, and is sometimes confounded with the preceding species.

Seventh species. Red-lead ore.

Its general colour is a hyacinth-red; it occurs massive but rarely, sometimes in membranes, but most commonly crystallized in broad oblique four-sided prisms, is both externally and internally splendent, very soft, between brittle and sectile, easily frangible, and heavy. It is found in veins in gneiss and mica slate, accompanied with other fossils of the same kind, in Austria, Savoy, and Siberia, and on account of its beautiful colour is chiefly used as a pigment.

Eighth species. Yellow-red ore.

Its principal colour is wax-yellow; it is generally crystallized in rectangular four-sided tables, cubes, octahedrons, equiangular eight-sided tables, and double eight-sided pyramids. Externally, it is shining and smooth, internally glistening, with a resinous lustre; it is translucent, soft, between brittle and sectile, easily frangible, and heavy. It is found in compact lime-stone in Carinthia, and some other countries of the continent.

Ninth species. Lead vitriol, or vitriol of lead.

The colour is yellowish-grey and greyish white; it occurs only crystallized in octahedrons of different figures. Externally it is shining, internally splendent, with an adamantine lustre. It is often semi-transparent, rather brittle, and heavy, and is found in Scotland, Anglesea, and Spain.

Tenth species. Lead earth.

Coherent lead earth is usually of a yellowish-grey colour; it occurs massive, is internally glimmering, usually opaque, soft, inclining to sectile, easily frangible, and heavy. It is found in primitive lime-stone in Derbyshire, Scotland, and many other countries. See PLUMBUM.

EIGHTH GENUS. *Tin.*

First species. Tin pyrites.

The colour is intermediate between steel-grey and brass-yellow; it occurs massive and disseminated. Internally is glistening, and has a metallic lustre, is semihard, brittle, easily frangible, and heavy. It melts easily, and has hitherto been found only in Cornwall.

Second species. Tin stone.

The most common colour is blackish-brown; it occurs massive, disseminated, in rolled pieces, in grains, like sand, but most frequently crystallized in prisms and pyramids of different figures. Internally it is shining and glistening, it yields a greyish-white streak, is hard, easily frangible, brittle, and very heavy. It is found only in primitive rocks, and is confined to a few situations, like all the tin genus.

Third species. Cornish tin ore, or wood tin.

The most usual colour is hair-brown, of different degrees of intensity; it occurs usually in rolled pieces, sometimes reniform with impressions. It is found usually in large and coarse granular distinct concretions, is opaque, hard, brittle, easily frangible, and uncommonly heavy. It is infusible, and hitherto has only been found in Cornwall in alluvial land, accompanied with tin stone. See STANNUM.

NINTH GENUS. *Bismuth.*

First species. Native Bismuth.

Its colour is silver-white, with an inclination to red; it occurs massive, disseminated in leaves, reticulated, and crystallized in small four-sided tables, and in small and indistinct cubes, and three-sided pyramids. It is soft, sectile, rather difficultly frangible, and uncommonly heavy; and is found in veins in primitive mountains in Saxony, and other parts of the continent; but it is doubtful if produced in Britain.

Second species. Bismuth glance.

The colour is a light lead-grey; it occurs massive, disseminated, and in acicular and capillary crystals; it soils, inclines to sectile, is easily frangible, and heavy. It is found always in veins, and is usually accompanied with native bismuth, chiefly in Saxony, Bohemia, and Hungary.

Third species. Bismuth-ochre.

The colour is a straw-yellow, passing into other neighbouring shades; it is massive and disseminated, opaque, soft, not very brittle, easily frangible, and heavy. This mineral is rare, and seems to be confined to a few places in Saxony and Bohemia. See BISMUTUM.

TENTH GENUS. *Zinc.*

First species. Blende.

Yellow blende is of a dark wax and sulphur yellow colour; it usually occurs massive and disseminated, but is sometimes crystallized in rectangular four-sided prisms; it is shining and splendent both externally and internally, with an adamantine lustre; is found in large and coarse granular distinct concretions, is usually translucent, semihard, brittle, easily frangible, and heavy. It phosphoresces when rubbed in the dark; occurs most frequently in transitive mountains in Bohemia, and other parts of Germany.

Second species. Calamine.

The general colour is yellowish-grey, which passes into other neighbouring shades: it occurs massive, disseminated, cellular, corroded, &c. and crystallized in tables, cubes, pyramids, and prisms. Externally the crystals are splendent and shining; internally, between shining and glimmering. It is usually found in small and fine granular distinct concretions, is semihard, not very brittle, rather difficultly frangible, and heavy; and is produced in beds in a floetz limestone formation, accompanied with iron-ochre, lead-glance, &c. It is met with in all the mine counties of England and Scotland, in Germany, and other parts of the continent; and when purified and roasted, is used for the fabrication of brass, which is a compound of zinc and copper. See ZINCUM.

ELEVENTH GENUS. *Antimony.*

First species. Native antimony.

The colour is perfect tin-white: it occurs massive, disseminated, reniform, and probably crystallized; in the fresh fracture it is splendent, and has a metallic lustre. It is found usually in coarse, small, and fine granular distinct concretions, is soft, sectile, easily frangible, and heavy in a low degree. It is produced in veins in Dauphiny and in the Harz, and disseminated in calx-par in Westermanriland, in Sweden; but is a rare mineral.

Second species. Grey antimony ore.

Compact grey antimony-ore is usually of a light lead-grey colour, occurs massive, disseminated, and occasionally in membranes; internally is shining and glistening with a metalliclu stre, is soft, not very heavy, easily frangible, soils, and becomes more shining in the streak. It is found in Sweden and some other countries, but is the rarest sub-species.

Third species. Black antimony ore

Is of an iron-black colour, occurs only crystallized in rectangular four-sided tables, is internally shining with a metallic lustre; is soft, rather sectile, and heavy. In Cornwall it is found of peculiar beauty.

Fourth species. Red antimony ore.

Its colour is cherry-red; it occurs massive, often in membranes, but most frequently in delicate capillary crystals; both externally and internally it is shining, and has an adamantine lustre. It is found in coarse, small, and longish granular distinct concretions, is opaque, not very brittle, and easily frangible; but is a very rare species.

Fifth species. White antimony ore.

It passes in colour from snow-white to several neighbouring shades; occurs massive and in membranes occasionally, but most commonly crystallized in rectangular four-sided tables, cubes, and acicular and capillary crystals. It is found in coarse and small granular distinct concretions, is translucent, soft, rather sectile and heavy. Before the blowpipe, it becomes wholly volatilized. It is found in veins in Bohemia, Hungary, and Saxony.

Sixth species. Antimony-ochre.

The colour is a straw-yellow, of various degrees of intensity; it seldom occurs massive and disseminated, but usually as a coating on crystals of grey antimony ore. It is dull, soft, not very brittle, nor particularly heavy. It is found always in veins, in different parts of Germany, and is evidently found by the decomposition of grey antimony ore. See STIBIUM.

TWELFTH GENUS. *Cobalt.*

First species. White cobalt ore.

When fresh fractured the colour is usually tin-white; it occurs massive, disseminated, &c. and also crystallized in cubes and double four-sided pyramids. It is found in coarse, small, and fine granular distinct concretions; is semihard, brittle, not very difficultly frangible, and heavy. It easily melts before the blowpipe, emits a strong arsenical smell, and yields a white metallic globule. It usually occurs in beds in primitive mountains, and is found in Sweden, Norway, and Silesia.

Second species. Grey cobalt ore.

On the fresh fracture its colour is light steel-grey inclining to white, but it becomes tarnished by exposure; it occurs only massive, disseminated, tubiform and specular; internally it is glimmering or glistening with a metallic lustre, is found in thick and curved lamellar distinct concretions, and is produced in Cornwall, Norway, and various other countries.

Third species. Cobalt glance.

The colour is a silver-white, slightly inclining to reddish: it is commonly massive and disseminated, sometimes crystallized in different forms; is externally splendent, internally between shining and glistening, and has a metallic lustre. It is semihard, brittle, and not very easily frangible; and when struck with steel, emits an arsenical smell. It is found in veins in various formations, in the different mine countries of the continent of Europe; and from it the greatest part of the cobalt in commerce is obtained, which is highly useful in the manufacture of glass, and as a paint.

Fourth species. Black cobalt ore.

Earthy black cobalt ore is of an intermediate colour between brownish and blueish-black, is composed of dull, dusky particles, which soil a little, usually cohering, streak shining, and very light.

Fifth species. Brown cobalt ochre

Is of a liver-brown colour, passing sometimes into other neighbouring shades; it occurs massive and disseminated, is internally dull, soft, sectile, easily frangible, and light; and appears to be peculiar to the floetz mountains in some parts of Germany and Spain.

Sixth species. Yellow cobalt ochre

Is usually of a dirty straw-yellow, occurs massive, frequently much bursted and corroded; it is internally dull, streak shining, soft, and rather friable, sectile, easily frangible, and light. It is the rarest species of cobalt ore, but most valued on account of its purity.

Seventh species. Red cobalt ochre.

Cobalt crust is of a peach blossom-red colour, of different degrees of intensity, occurs most frequently in velvety drusy coatings, and disseminated, is feebly glimmering, bordering on dull, scarcely soils, has a shining streak, and is very soft and light. See COBALTUM.

THIRTEENTH GENUS. *Nickel.*

First species. Copper nickel

Is of a red copper-colour of different degrees of intensity; it occurs usually massive and disseminated, is internally glistening, and has a metallic lustre. It is usually unseparated; sometimes, however, it is found in coarse and small granular distinct concretions, is semihard, in a high degree brittle, not very easily frangible, and heavy. Before the blowpipe it emits an arsenical smell and odour, and afterwards melts, though with difficulty. It is found in Cornwall, Norway, and many other countries, and is nearly allied to cobalt.

Second species. Nickel ochre

Is of an apple-green colour, occurs always as a coating or efflorescence, is composed of dull dusty particles, loose, or little cohering, feels meagre, and is light. It is found in the same situations with the preceding species. It is not certain that native nickel has yet been discovered, though it is mentioned by some mineralogists. See NICCOLUM.

FOURTEENTH GENUS. *Manganese.*

First species. Grey manganese ore.

Radiated grey manganese ore is of a dark steel-grey colour, occurs massive, disseminated, and crystallized in prisms of different varieties. It is found in coarse, large, and small granular distinct concretions; soils strongly when rubbed, is soft, brittle, rather difficultly frangible, and not particularly heavy. It is produced in several counties of England and Scotland, and in different parts of Germany.

Second species. Black manganese ore

Is of an intermediate colour between brownish-black and dark-greyish black, occurs massive, disseminated, and in octahedral crystals. It is found in small and fine granular concretions; is opaque, semihard, brittle, and heavy; but is a rare mineral, and hitherto found only in a few places of Germany and Spain.

Third species. Red manganese ore

Is of a light rose-red colour, occurs massive and disseminated, is internally dull, translucent in a slight degree, hard, brittle, easily frangible, and heavy. It is found in veins in Norway, France, and some other countries. See MAGNESIUM.

FIFTEENTH GENUS. *Molybdena.*

First species. Molybdena.

Its colour is a fresh burning lead-grey; it occurs usually massive and disseminated, but also crystallized in six-sided tables, and short six-sided prisms; internally it is splendent, the fracture perfectly foliated, and is found in large and coarse granular distinct concretions. It soils a little, is very soft, easily frangible, its thin leaves common flexible, sectile, feels greasy, and is heavy. It is one of the oldest of metals, and occurs only in primitive mountains, disseminated, or in veins; and is produced in Norway, Sweden, Bohemia, and other countries. See MOLYBDÆNUM.

SIXTEENTH GENUS. *Arsenic.*

First species. Native arsenic.

When fresh broken it is of a light whitish lead-grey colour, but it speedily tarnishes; it occurs massive, disseminated, reniform, and in plates, with various impressions. It is found in thin, curved, lamellar, distinct concretions; in the streak it becomes shining and metallic, semihard in a high degree, very easily frangible, and between sectile and malleable. It occurs only in primitive mountains, and in veins of a newer formation, and is found in various parts of Germany, in France, and in Chili.

Second species. Arsenic pyrites.

Common arsenic pyrites is, when fresh, of a silver-white colour, but soon acquires a yellowish tarnish; it occurs massive, disseminated, and also in crystals of various figures. Internally, it is shining, with a metallic lustre; and is found usually unseparated, is hard, brittle, not easily frangible, and heavy. It occurs only in primitive mountains and in beds, and is produced in Norway, Germany, and Siberia. From this ore the white oxide of arsenic is principally obtained.

Third species. Orpiment.

Red orpiment is of an aurora-colour, of different degrees of intensity: it occurs massive, disseminated in membranes, and also crystallized in oblique four-sided and six-sided prisms. It is translucent, but the crystals are transparent, is very soft, yields a lemon or orange-coloured streak, and is easily frangible. It is found both in primitive and floetz mountains, and is produced in Germany, France, Italy, and the West Indies. It is used as a pigment.

Yellow orpiment is of a perfect lemon-yellow colour, occurs massive, and in very minute crystals, is found in large, coarse, and small angular granulated distinct concretions, is translucent, very soft, sectile, and common flexible. It occurs principally in floetz mountains, in several parts of Germany and the East.

Fourth species. Arsenic bloom.

The colour is a reddish-white and snow-white; it occurs as a coating, in small balls, &c. and in very delicate capillary shining crystals, is translucent on the edges, very soft, easily frangible, and soils. It is produced in rents of a granite rock, and hitherto has only been discovered in Swabia. See ARSENICUM.

SEVENTEENTH GENUS. *Scheele.* *

First species. Tungsten.

The colour is usually yellowish and greyish-white, which pass into several other neighbouring shades; it occurs massive, disseminated, and frequently crystallized. Internally it is shining, with a vitreous lustre; is more or less translucent, soft, not very brittle, and uncommonly heavy. It is found in primitive mountains, and belongs to the oldest metalliferous formations, and is produced in Cornwall, Sweden, Saxony, and Bohemia. See TUNGSTENUM.

Second species. Wolfram.

Is of an intermediate colour between dark greyish-black, and brownish black; it occurs massive, and also crystallized in broad six-sided prisms, and rectangular four-sided tables; and is found in fortification-wise curved lamellar distinct concretions. It is opaque, yields a reddish-brown streak, is soft, brittle, and uncommonly heavy. It is produced in the primitive mountains, almost always accompanied with tin, in Cornwall, and some other countries. See TUNGSTENUM.

---

* So called in honour of the illustrious Scheele.

EIGHTEENTH GENUS. *Menachine.*

First species. Menachanite

Is of a greyish black colour, inclining to iron-black, occurs only in small flattish angular grains. Internally is glistening, with an adamantine lustre, is perfectly opaque, soft, brittle, retains its colour in the streak, is easily frangible, and moderately heavy. It is attractable by the magnet, and is found in Cornwall, accompanied by fine quartz-sand, in the isle of Providence in America, and at Botany Bay.

Second species. Octrahedrite.

Its colour passes from indigo-blue to many other shades; it occurs only crystallized, and that in very acute octahedrons. It is chiefly translucent, and semitransparent, semihard, brittle, and borders on heavy. It is found in Dauphiny, and appears from accurate experiments to be an oxide of menachine mixed with silica.

Third species. Rutile

Is of a dark blood-red colour, of various degrees of intensity; it occurs always crystallized in four-sided and six-sided prisms, and also in compressed acicular and capillary crystals. Externally it is shining, internally splendent, translucent in a slight degree, hardish, easily frangible, and not very heavy. It is found imbedded in drusy cavities of granite, &c. in different parts of Germany, France, Spain, Siberia, and South Carolina.

Fourth species. Nigrine

Is of a dark brownish-black colour, passing to velvet-black; it occurs in larger and smaller angular grains, and in rolled pieces. Externally moderately glittering, internally the same, with an adamantine lustre, is opaque, semihard, brittle, and yields a yellowish-brown streak. It is found in alluvial hills in several parts of Germany, and also in Ceylon.

Fifth species. Iserine

Is of an iron-black colour, somewhat inclining to brownish-black; it occurs usually in small obtuse angular grains, and in rolled pieces, internally glistening, with a semimetallic lustre, is completely opaque, hard, brittle, and retains its colour in the streak. Hitherto it has been found only in the stream called Iser in Germany, from which it receives its appellation. It bears a great resemblance to iron-sand. See TITANIUM.

NINETEENTH GENUS. *Uran.*

First species. Pitch ore

Is usually of a velvet-black colour; it occurs almost always massive and disseminated. Internally is shining, soft, brittle, uncommonly heavy, and completely infusible without addition. It is found in veins of primitive mountains along with lead and silver ores, and is produced in Saxony and Norway.

Second species. Uran mica.

The principal colour is a grass-green, passing into various allied shades; it occurs sometimes in membranes, but commonly crystallized in rectangular four-sided tables. The fracture is foliated, the fragments and distinct concretions are too minute to be determined. It is more or less translucent, soft, sectile, easily frangible, and is found in iron-stone veins in Cornwall, Saxony, and France.

Third species. Uran ochre.

Friable uran ochre is usually of a straw-yellow colour: it generally occurs as a coating or efflorescence on pitch ore; is friable, and composed of dull dusty particles, which feel meagre, and are not particularly heavy.

Indurated uran ore is of the same colour as the preceding: occurs massive and disseminated, is generally dull, internally opaque, soft, brittle, and soils a little, and is found along with the other ores of uran. See URANIUM.

TWENTIETH GENUS. *Sylvan.*

First species. Native sylvan

Is of an intermediate colour between white and silver-white: occurs massive and disseminated, and also crystallized in four and six-sided prisms, in small three-sided pyramids, in cubes, and in short acicular crystals. It is soft, not very brittle, easily frangible, and heavy; and before the blowpipe melts as easily as lead, burning with a light green colour, and emitting a sharp, disagreeable odour. Hitherto it has only been found at Facebay, in Transylvania.

Second species. Graphic ore.

Its colour is a light steel-grey: it occurs massive and crystallized; externally is splendent, internally glistening. When massive, it shews a tendency to fine granular distinct concretions: it is soft, brittle, sectile, and heavy, and is worked as an ore of gold in Transylvania, where alone it has yet been found.

Third species. Yellow sylvan ore

Is of a silver-white colour, inclining to brass-yellow: it occurs disseminated and crystallized in very small and rather broad four-sided prisms; is soft, rather sectile, and uncommonly heavy. It is found along with the other species of the genus, and contains a considerable portion both of gold and silver.

Fourth species. Black sylvan ore

Is of an intermediate colour between iron-black and blackish lead-grey: it occurs massive, and in small, thin, and longish six-sided tables, which are usually imbedded. Externally it is splendent; internally shining, soils a little, is very soft, sectile, splits easily, and in thin leaves is common flexible. It melts easily before the blowpipe; occurs in veins along with other minerals, but is only found in Transylvania, where it is worked for the gold and silver it contains. See TELLURIUM.

TWENTY-FIRST GENUS. *Chrome.*

First species. Acicular, or needle ore.

Its colour is dark steel-grey: occurs in imbedded acicular crystals: internally shines with a metallic lustre, is soft, not very brittle, heavy, and is always accompanied with chrome ochre, and sometimes with native gold. It is found in Siberia.

Second species. Chrome ochre

Is of a verdigris green, passing through several neighbouring shades: it occurs massive, disseminated, and in membranes; is dull, soft, not very heavy, and is found with the preceding species. See CHROMIUM.

Having already extended this article to a greater length than was intended, in order that we might be able to give a satisfactory view of the beautiful system of Werner, we shall only subjoin the names of some other minerals, which either have not been regularly classed, or are but recently discovered, and therefore have not been accurately investigated: these are

Earthy fossils, foliated prehnite, schmelzstein, spodumene, meionite, somnite, glassy felspar, spinthere, metallic fossils, pitchy iron ore, gadolinite, copper-sand or muriat of copper, phosphat of copper, corneous lead ore, reniform lead ore, bournonite, columbite, tantalite, yttertantalite. Of these however several will be found noticed in their alphabetical arrangement.

To which may be added loisite, needle or acicular-stone, fish eye-stone, iron-clay, figure-stone, granular actynolite, dolomite, foliated celestine and its varieties, silver black with its sub-species.

For the various figures assumed by mineral substances on crystallizing, see the article CRYSTALLOGRAPHY, and Plate 107, subjoined to that article.

MINERVA, the goddess of wisdom, war, and all the liberal arts, was produced from Jupiter's brains without a mother. The god married Metis, whose superior prudence made him apprehend that the children of such an union would be more intelligent than their father. To prevent this, Jupiter devoured Metis in her pregnancy, and, some time after, to relieve the pains which he suffered in his head, he ordered Vulcan to cleave it open. Minerva came all armed and grown up from her father's brain, and immediately was admitted into the assembly of the gods. The power of Minerva was great in heaven, and she was the only one of all the divinities whose authority and consequence were equal to those of Jupiter. The actions of Minerva are numerous. Her quarrel with Neptune concerning the right of giving a name to the capital of Cecropia deserves attention. The assembly of the gods settled the dispute by promising the preference to whomsoever of the two gave the most useful present to the inhabitants of the earth. Neptune, upon this, struck the ground with his trident, and immediately a horse issued from the earth. Minerva produced the olive, and obtained the victory by the unanimous voice of the gods, who observed, that the olive, which is the emblem of peace, is far preferable to the horse, which is the symbol of war. The victorious deity called the capital Athenæ, and became the tutelar goddess of the place. Minerva was always very jealous of her power, and the manner in which she punished the presumption of Arachne is well known. (Vide ARACHNE.) The attempts of Vulcan to offer her violence are strong marks of her virtue. (Vide ERICHTHONIUS.) She was known among the ancients by many names. She was called Athena, Pallas, (vide PALLAS.) Parthenos, from her remaining in perpetual celibacy. The worship of Minerva was universally established; she had magnificent temples in Egypt, Phœnicia, all parts of Greece, Italy, Gaul, and Sicily. The festivals celebrated in her honour were solemn and magnificent. (Vide PANATHENÆA.) She was invoked by every artist, and particularly such as worked in wool, embroidery, painting, and sculpture. Minerva was represented in different ways, according to the different characters in which she appeared. She usually was represented with a helmet on her head, with a large plume nodding in the air. In one hand she held a spear, and in the other a shield, with the dying head of Medusa upon it. Sometimes this Gorgon's head was on her breast-plate, with living serpents writhing round it, as well as her shield and helmet. When she appeared as the goddess of the liberal arts, she was arrayed in a variegated veil, which the ancients called peplum. She was partial to the olive tree; the owl and the cock were her favourite birds, and the dragon among reptiles was sacred to her.

Cicero, L. 3. de Nat. Deor. speaks of five Minervas: the first, which he says was the mother of Apollo: the second brought forth by the Nile, which the Egyptian Saites worshipped. Plutarch in his treatise of Osiris, says that the image of Minerva or Pallas was in the city of Sai, with this inscription: Εγω ειμι παν το γεγονος, και ον, και εσομενὸν, καὶ τον εμον πεπλον εδεις πω θνητος απεκαλυψεν, "I am all that was, is, and is to come; and my veil no mortal hath hitherto uncovered:" the third is she that came out armed from Jupiter's brain: the fourth was the daughter of Jupiter and Corypha, the daughter of Oceanus, who invented chariots with four wheels: the fifth was the daughter of Pallantis, whom she killed because he would have ravished her: this last they made to have wings to her feet, in the same manner as Mercury. Arnobius pursues the same distinction. We may with certainty conclude, that the second of these Minervas is the most ancient of any of them. Plato in his Timæus, speaking of the city of Sai, says, that Minerva was worshipped there, and called by the name of Neith. Syncellus intimates that the name of queen Nitotris, which includes that of Neith, signified as much as victorious Minerva. Plutarch speaks also of the Minerva of Sai, and says that some made no distinction between her and Isis.

The Phœnicians, according to the relation given us by Sanchniatho, had their Minerva also, and they made her to be the daughter of Saturn, and attributed the invention of arts and arms unto her: this is what Eusebius says of her: "Saturnus liberos procreavit, Proserpinam et Minervam; ac prior quidem Virgo diem obiit; Minerva autem Mercurioque auctoribus falcem ex ferro hastamque conflavit." It was from the Egyptians or Phœnicians that the Greeks borrowed their Minerva, and Cecrops was the first who taught the Athenians to worship Minerva and Jupiter, as Eusebius says. The conveniency of neighbourhood made Minerva pass from Egypt into Lybia before Cecrops went over into Greece. Herodotus assures us the Lybians made her to be the daughter of Neptune, and the lake Triton, though afterwards upon the account of some misunderstanding between her and her father, she went to Jupiter, who adopted her for his daughter. Pausanias assures us the Athenians were much devoted to the worship of the Gods, and that they were the first who gave Minerva the name of εργανη, *operaria, machinatrix.* He says elsewhere, they built a temple to Minerva, Μαχανιτις, *machinatrix,* as being the goddess that had introduced arts and inventions into the world: he speaks moreover of a statue of Minerva that fell from heaven. He says Minerva aided Perseus in his conflict against Gorgon, near the lake Triton, for which reason that country was consecrated to her. Lastly, the said author declares, the Bœotians affected to give the name of Triton to a brook that run near Minerva's temple, from which she had been named Tritonia. As for Minerva, says St. Augustine, L. 18. C. 9. de Civ. Dei, "She is much more ancient than Mars or Hercules, and they said she lived in the days of Ogyges, near unto the lake Triton, from whence she was named Tritonia: she was the inventress of many rare and useful things; and men were so much the more inclined to believe she was a goddess because her original was not known; for as to the story of her coming full armed from the head of Jupiter, that is manifestly a fable of the poets."

MINERVALIA, festivals at Rome in honour of Minerva, celebrated in the months of March and June. During the solemnity scholars obtained some relaxation from their studious pursuits, and the present, which it was usual for them to offer to their masters, was called Minerval, in honour of the goddess Minerva, who patronized literature.

MINFELD, a town of Germany, in the duchy of Deux Ponts, eight miles S. of Landau.

To MI'NGLE. *v. a.* 1. To mix; to join; to compound; to unite with something so as to make one mass (*Rogers*). 2. To contaminate; to make of dissimilar parts (*Rogers*). 3. To confuse (*Milton*).

To MI'NGLE. *v. n.* To be mixed; to be united with (*Rowe*).

MI'NGLE. *s.* (from the verb.) Mixture; medley; confused mass (*Dryden*).

MI'NGLER. *s.* He who mingles.

MINGRELIA, a province of Asia, which makes parts of Georgia; bounded on the W. by the Black Sea, on the E. by Imeritia, on the S. by a part of Georgia, and on the N. by Circassia. It is governed by a prince, who is tributary to the sovereign of Imeritia. The face of this country, its products, and the customs and manners of the inhabitants, are similar to those of Georgia.

MINIATO, ST. an episcopal town of Tuscany, seated on the Arno, 20 miles SW. of Florence. Lon. 10. 45 E. Lat. 43. 40 N.

MINIATURE, or MIGNATURE, a delicate kind of painting, consisting of little points or dots, instead of lines; usually done on vellum, ivory, or paper, with very thin, simple water-colours.

The word comes from the Latin *minium*, red lead; that being a colour much used in this kind of painting. The French frequently call it *mignature*, from *mignon*, fine, pretty, on account of its smallness and delicacy: and it may be ultimately derived from μικρος, small.

Miniature is distinguished from other kinds of painting by the smallness and delicacy of its figures, the weakness of their colours, and faintness of the colouring; and on this account it requires to be viewed very near.

Those colours that have the least body are the best and most commodious for painting in miniature; such are carmine, ultramarine, fine lakes, and green made of the juices of several kinds of herbs and flowers.

The colours commonly used in miniature painting are for red, carmine, lake, rose-pink, vermilion, red lead, scarlet-oker, common Indian red, red oker, Venetian red, and Spanish brown; for blue, ultramarine, ultramarine ashes, Prussian blue, verditer, indigo, smalt, blue bice, and litmus: for yellow, gamboge, Naples yellow, Dutch pink, English pink, gall-stone, masticot, French berry wash, turmeric wash, zedoary wash, and tincture of saffron: for green, sap-green, verdigrise, distilled verdigrise, and terra verte: for purple, true Indian red, archal, and logwood wash: for brown, bistre, umbre, brown oker, Cologn earth, and terra japonica: for white, flake white, white lead, calcined hartshorn, pearl white, Troy white, lake white, and egg-shell white: and for black, Indian ink, lamp black, ivory black, and blue black.

Painting in miniature is the nicest and most tedious of all others; being performed wholly with the point of the pencil.

There are some painters who never use any white colour in miniature, but make the ground of the vellum serve to raise their figures; in which case, the lights appear bright in proportion to the depth and strength of the colours of the figures. Others before they go to work, give the vellum a light wash with white lead, well prepared and purified.

When paper of any proper kind is used, it is sufficient to prime it with isinglass size, thickened properly with pearl white, and any pigment which will give the ground the desired colour. But common paper may be rendered stronger and fitter for receiving the colours, by laying on the back of it a coat of starch, boiled with water to a moderate consistence, and rendered more tenacious by the addition of a little isinglass. This should be laid on very smoothly with a brush, and the paper, when nearly dry, must be put betwixt two leaves of a book, or betwixt two sheets of paper and two boards, and compressed by a weight laid upon them. Two sheets of paper cemented together by the starch and isinglass, and treated in the same manner, make a very commodious substance for painting in miniature. Vellum requires only to be strained on a pasteboard, and primed in the same manner; and if it should be greasy, rubbed over with the gall of any beast.

When the colours are laid on flat without dotting, though the figures be small, and the ground either vellum or paper, it is not called miniature, but washing.

The colours for miniature may be mixed up with a solution of gum arabic, or gum tragacanth, in water, or with isinglass size.

MI'NIKIN. *a.* Small; diminutive (*Shaks.*).

M'inikin. *s.* A small sort of pins.

MI'NIM. *s.* (from *minimus*, Latin.) A small being; a dwarf (*Milton*).

Minim, in music, a note, or character of time; equal to two crotchets, or half a semibreve.

The invention of the minim is ascribed to a certain priest in Navarre, but the first who used it was Philip de Vitriaco, in whose time it was the smallest note in practice. See Time, Characters, and Music.

MINIMA NATURÆ, or Minima naturalia, among philosophers, the primary articles, whereof bodies consist; the same with what are otherwise called corpuscles, and atoms.

Minima, in the higher geometry, the smallest quantities attainable in any given case. See Maximum.

MI'NIMUS. *s.* (Latin.) A being of the least size (*Shakspeare*).

MI'NION. *s.* (*mignon*, French.) A favourite; a darling; a low dependant (*Swift*).

MI'NIOUS. *a.* (from *minium*, Latin.) Of the colour of red lead or vermilion (*Brown*).

To MI'NISH. *v. a.* (from *diminish*; *minus*, Lat.) To lessen; to lop; to impair (*Psalms*).

MI'NISTER. *s.* (*minister*, Latin.) 1. An agent; one who is employed to any end; one who acts under another (*Sidney*). 2. One who is employed in the administration of government (*Bacon*). 3. One who serves at the altar; one who performs sacerdotal functions (*Addison*). 4. A delegate; an official (*Shaks.*). 5. An agent from a foreign power.

Minister of state, a person to whom the prince intrusts the administration of government. See Council.

Minister (Foreign), is a person sent into a foreign country, to manage the affairs of his province, or of the state to which he belongs. Of these there are two kinds: those of the first rank are embassadors and envoys extraordinary, who represent the persons of their sovereigns; the ministers of the second rank are the ordinary residents.

To Mi'nister. *v. a.* (*ministro*, Latin.) To give; to supply; to afford (*Otway*).

To Mi'nister. *v. n.* 1. To attend; to serve in any office (*Milton*). 2. To give medicines (*Shakspeare*). 3. To give supplies of things needful; to give assistance; to contribute; to afford (*Smalr.*). 4. To attend on the service of God (*Romans*)

MINISTE'RIAL. *a.* (from *minister.*) 1. Attendant; acting at command (*Brown*). 2. Acting under superior authority (*Rogers*). 3. Sacerdotal; belonging to the ecclesiastics or their office (*Hooker*). 4. Pertaining to ministers of state.

MINISTE'RIALLY. *ad.* In a ministerial manner (*Waterland*).

MI'NISTERY. *s.* (*ministerium*, Latin.) Office; service: commonly *ministry* (*Digby*).

MI'NISTRAL. *a.* (from *minister.*) Pertaining to a minister.

MI'NISTRANT. *a.* (from *minister.*) Attendant; acting at command (*Milton*).

MI'NISTRA'TION. *s.* (from *ministro*, Lat.). 1. Agency; intervention; office of an agent delegated or commissioned by another (*Taylor*). 2. Service; office; ecclesiastical function.

MI'NISTRY. *s.* (contracted from *ministery.*) 1. Office; service (*Sprat*). 2. Office of one set apart to preach; ecclesiastical function (*Locke*). 3. Agency; interposition (*Bentley*). 4. Business (*Dryden*). 5. Persons employed in public affairs of state (*Swift*).

MINIUM, in the arts, red lead, and oxide of lead. See Lead.

MINNIN, a stringed instrument of music among the ancient Hebrews, having three or four chords to it; though there is reason to question the antiquity of this instrument; both because it requires a hair-bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol. Kircher took the figures of this, the machul, chinnor, and psaltry, from an old book in the Vatican library.

MINO, a river of Spain, which rises in Galicia, near Castro del Rey, and passing by Lugo, Ortense, and Tey, it then divides Galicia from Portugal, and falls into the Atlantic Ocean at Caminha.

MI'NOR. *a.* (Latin.) 1. Petty; inconsiderable (*Brown*). 2. Less; smaller (*Clarendon*).

Minor, a Latin term, literally denoting less; used in opposition to major, greater.

Minor, in law, denotes a person under age; or who, by the laws of the country, is not yet arrived at the power of administering his own affairs, or the possession of his estate. Among us, a person is a minor till the age of twenty-one: before which time his acts are invalid. (See Age and Infant.) It is a maxim in the common law, that in the king there is no minority, and therefore he hath no legal guardian; and his royal grants and assents to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one. It is also provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age. This is likewise expressly declared by stat. 7 and 8 Will. III. cap. 25. with regard to the house of commons.

Minor, in logic, is the second proposition of a formal or regular syllogism, called also the assumption.

Minor, in music, is applied to certain concords, which differ from or are lower than others of the same denomination by a lesser semitone or four commas. Thus we say, a third minor, or lesser third, or a sixth major and minor. Concords that admit of major and minor, i. e. greater and less, are said to be imperfect concords.

To MI′NORATE. *v. a.* (from *minor*, Lat.) To lessen; to diminish (*Glanville*).

MINORA′TION. *s.* (from *minorate.*) The act of lessening; diminution; decrease (*Brown*).

MINORBINO, a town of Naples, in Terra di Bari, with a bishop's see, twenty-six miles N. of Cirenza. Lon. 16. 19 S. Lat. 41. 8 N.

MINORCA, an island of the Mediterranean, lying fifty miles to the N.E. of Majorca. It is thirty miles long and twelve broad; and is a mountainous country, with some fruitful valleys, where there are excellent mules. Cittadella is the capital; but the town of Mahon claims greater consequence, on account of its excellent harbour, called Port Mahon, which is defended by Fort St. Philip, one of the strongest fortresses in Europe, and on the fate of which the whole island depends. Minorca was taken by the English in 1708, and confirmed to them by the treaty of Utrecht. The French took it in 1756; but it was restored in 1763. It was retaken by the Spaniards in 1782, and confirmed to them by the peace of 1783. It was again taken by the English, without the loss of a man, in 1798. Port Mahon lies in Lon. 3. 48 E. Lat. 39. 50 N.

MINORI, a town of Naples, in Principato Citeriore, with a bishop's see. It is seated on the gulf of Salerno, between the town of that name and Amalfi.

MINO′RITY. *s.* (from *minor*, Latin.) 1. The state of being under age (*Shakspeare.*) 2. The state of being less (*Brown*). 3. The smaller number.

MINOS, a king of Crete, son of Jupiter and Europa, who gave laws to his subjects, B.C. 1406, which still remained in full force in the age of the philosopher Plato. His justice and moderation procured him the appellation of the favourite of the gods, and the wise legislator, and, according to the poets, he was rewarded for his equity, after death, with the office of supreme judge in the infernal regions. In this capacity he is represented sitting in the middle of the shades, and holding a sceptre in his hand. The dead plead their different causes before him, and the impartial judge shakes the fatal urn, which is filled with the destinies of mankind. The second was a son of Lycastes, the son of Minos I. and king of Crete. He married Pasiphae, the daughter of Sol and Perseis, and by her he had many children. He showed himself cruel in the war which he carried on against the Athenians, who had put to death his son Androgeus. (See Androgeus.) He took Megara by the treachery of Scylla, (vide Scylla); and not satisfied with a victory, he obliged the vanquished to bring him yearly to Crete seven chosen boys, and the same number of virgins, to be devoured by the Minotaur. (Vide Minotaurus.) This bloody tribute was at last abolished when Theseus had destroyed the monster. (Vide Theseus.) He was at last put to death by Cocalus king of Sicily, who had given an asylum to Dædalus, (vide Dædalus) whom he pursued from Crete for ministering to the unnatural desires of Pasiphae.

MINOTAURUS, a celebrated monster, half a man and half a bull, according to Ovid. It was the fruit of Pasiphae's amour with a bull. Minos refused to sacrifice a white bull to Neptune, an animal which he had received from the god for that purpose. This offended Neptune, and he made Pasiphae, the wife of Minos, enamoured of this bull. Dædalus prostituted his talents in being subservient to the queen's unnatural desires, and, by his means, Pasiphae's horrible passions were gratified, and the Minotaur came into the world. Minos confined in the labyrinth a monster which shewed his wife's indecency. The Minotaur was at length killed by Theseus, who was one of the tributary Athenian youths to be devoured by it. Theseus received, it is said, a clue from Ariadne, which served to extricate him from the mazes of the labyrinth, and to effect his escape after he slew the Minotaur. The tradition of the Minotaur, and of the commerce of Pasiphae with a bull, is explained by making her enamoured of one of her husband's courtiers, called Taurus, whom she met at the house of Dædalus, and also by supposing her to bring forth twins, one resembling Minos, the other Taurus.

MINOW, in ichthyology. See Cyprinus.

MINSFELDEN, or Mensfelden, a town of Germany, in the archbishopric of Treves, 25 miles E. of Coblentz. Lon. 7. 57 E. Lat. 50. 26 N.

MINSINGEN, a town of Suabia, in the duchy of Wirtemberg, with a castle. Lon. 9. 35 E. Lat. 48. 32 N.

MINSKI, a town of Lithuania, capital of a palatinate of the same name, with two citadels. The country is pretty fertile, and has forests containing vast numbers of bees, whose honey makes part of its riches. Minski is 65 miles N. of Sluczk, and 100 S.E. of Wilna. Lon. 26. 48 E. Lat. 54. 11 N.

MI′NSTER. *s.* (mınꞅꞇéꞃe, Saxon.) A monastery; an ecclesiastical fraternity; a cathedral church.

MINSTREL, in ancient customs, certain persons who combined the character of poet and musician, and whose profession it was to wander about the countries they inhabited, singing panegyrical songs and verses on their occasional benefactors, accompanying them with some musical instrument.

Borel derives the word from *manus* and *histrio*, one who diverts with the hand; or from *minor histrio*, little buffoon: Du Cange from *ministellus*, a diminutive of minister, because the minstrels were anciently ranked among the lower officers, ministers, or servants.

According to Dr. Percy in his Essay on the Ancient English Minstrels, the word is derived from the French *menestrier*; and was not in use here before the Norman conquest: and it is remarkable, that our old monkish historians do not use the word *citharoedus, cantator*, or the like, to express a minstrel in Latin; but either *mimus, histrio, joculator*, or some other word that implies gesture. Hence it should seem that the minstrels set off their singing by mimickry or action; or, according to Dr. Brown's hypothesis, united the powers of melody, poem, and dance. These minstrels were probably the genuine successors of the ancient bards, who joined the arts of poetry and music, and sung verses to the harp of their own composing. After the conversion of the Saxons to Christianity, the poets and minstrels became two separate professions: and the latter continued to be a distinct order of men, and got their livelihood by singing verses to the harp at the houses of the great: where they were hospitably and respectfully received, retaining many of the honours shewn to their predecessors the bards and scalds. And though some of them only recited the compositions of others, many of them still composed songs themselves, and all of them could probably invent a few stanzas on occasion. There are two remarkable facts in history, which prove that the profession of a minstrel was held in great reverence among the Saxon tribes, as well as among their Danish brethren. In the year 878, when king Alfred wished to learn the true situation of the Danish army, which had invaded his realm, he assumed the dress and character of a minstrel, *fingens se joculatorem, assumpta cithara*, &c. and under this character, though he could not be known to be a Saxon, obtained an honourable reception. About sixty years after a Danish king made use of the same disguise to explore the camp of our king Athelstan. The minstrel was, therefore, a privileged character with both these people: and so late as the reign of Edward II. the minstrels were easily admitted into the royal presence; an instance of which is mentioned by Stow, Survey of London, 1703, p. 469. In the fourth year of Richard II. John of Gaunt erected at Tutbury, in Staffordshire, a court of minstrels, with full power to receive suit and service from the men of this profession within five neighbouring counties, to enact laws and determine their controversies, &c. for which they had a charter. (See Plott's Hist. Staff. p. 435, &c.) The minstrels continued down to the reign of Elizabeth; in whose time, however, they had lost much of their dignity, and were sinking into contempt and neglect; yet still they sustained a character far superior to any thing we can conceive at present of old ballads. Towards the end of the sixteenth century this class of men lost all credit, and were sunk so low in the public opinion, that in the thirty-ninth year of Elizabeth a statute was passed, by which minstrels, wandering abroad, were included among rogues, vagabonds, and sturdy beggars, and were adjudged to be punished as such. This act seems to have put an end to the profession, for after this time they are no longer mentioned. Judge Blackstone observes, that in some manors the copyholders were bound to perform many servile offices for the lord, who found them meat and drink, and sometimes, (as is still the use in the highlands of Scotland) a minstrel or piper for their diversion. Comm. b. ii. p. 96.

MI'NSTRELSY. *s.* (from *minstrel.*) 1. Music; instrumental harmony. (*Davies*). 2. A number of musicians (*Milton*).

MINT. *s.* (minꞇe, Saxon.) in botany. See MENTHA.

MINT (Cat). See NEPETA.

MINT (Pepper). See MENTHA.

MINT, the place in which the king's money is coined. (See COINAGE.) There were anciently mints in almost every county in England; but the only mint at present in the British dominions is that in the Tower of London. The officers of the mint are, 1. The warden of the mint, who is the chief; he oversees the other officers and receives the bullion. 2. The master-worker, who receives bullion from the warden, causes it to be melted, delivers it to the moneyers, and, when it is coined, receives it again. 3. The comptroller, who is the overseer of all the inferior officers, and sees that all the money is made to the just assize. 4. The assay-master, who weighs the gold and silver, and sees that it is according to the standard. 5. The two auditors, who take the accounts. 6. The surveyor of the melting; who, after the assay-master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver; who engraves the stamps and dyes for the coinage of the money. 8. The clerk of the irons; who sees that the irons are clean and fit to work with. 9. The melter; who melts the bullion before it be coined. 10. The provost of the mint; who provides for and oversees all the moneyers. 11. The blanchers, who anneal and cleanse the money. 12. The moneyers; some of whom forge the money, some share it, some round and mill it, and some stamp and coin it. 13. The porters, who keep the gate of the mint.

Mint was also a pretended place of privilege, in Southwark, near the King's Bench, put down by statute. If any persons, within the limits of the mint, shall obstruct any officer in the serving of any writ or process, &c. or assault any person therein, so as he receive any bodily hurt, the offender shall be guilty of felony, and be transported to the plantations, &c. Stat. 9. Geo. I.

MINT, is also used figuratively for any place of invention.

To MINT. *v. a.* (from the noun.) 1. To coin; to stamp money (*Bacon*). 2. To invent; to forge (*Bacon*).

MI'NTAGE. *s.* (from *mint*). 1. That which is coined or stamped (*Milton*). 2. The duty paid for coining (*Ainsworth.*)

MI'NTER. *s.* (from *mint*) Coiner (*Cam.*).

MINTHE, a daughter of Cocytus, loved by Pluto. Proserpine discovered her husband's amour, and changed his mistress into an herb, called by the same name, *mint*.

MI'NTMAN. *s.* (*mint* and *man.*) One skilled in coinage (*Bacon*).

MI'NTMASTER. *s.* (*mint* and *master.*) 1.

One who presides in coinage (*Boyle*). 2. One who invents (*Locke*).

MINTURNÆ, a town of Campania, between Sinuessa and Formiæ. It was in the marshes of its neighbourhood that Marius concealed himself in the mud, to avoid the partizans of Sylla. (See MARIUS.)

MINUET, (from the French *menu*, little, and signifying a small pace.) A movement of three crotchets or three quavers in a bar; of a slow and graceful motion, and always beginning with the beating note. This is the dancing minuet, and is said to have been invented at Poitou: but there are other minuets of a time somewhat quicker, and which were formerly much used as concluding movements of overtures, sonatas, &c.

MI'NUM. *s.* 1. (With printers.) A small sort of printing letter. 2. (With musicians.) A note of slow time. See MINIM.

MINU'TE. *a.* (*minutus*, Lat.) Small; little; slender; small in bulk (*South*).

MI'NUTE. *s.* (*minutum*, Latin.) 1. The sixtieth part of an hour (*Shakspeare*). 2. Any small space of time (*South*). 3. The first draught of any agreement in writing.

To MINU'TE. *v. a.* (*minuter*, French.) To set down in short hints (*Spectator*).

MINUTE is the 60th part of a degree, or of an hour. The minutes of a degree are marked with the acute accent, thus ′; the seconds by two, ″; the thirds by three, ‴. The minutes, seconds, thirds, &c. in time, are sometimes marked the same way; but, to avoid confusion, the better way is by the initials of the words; as minutes $^{\mathrm{m}}$, seconds $^{\mathrm{s}}$, thirds $^{\mathrm{t}}$, &c.

MINUTE, in architecture, usually denotes the 60th part of a module, but sometimes only the 30th part.

MI'NUTE-BOOK. *s.* (*minute* and *book*.) Book of short hints.

MI'NUTE-GLASS. *s.* (*minute* and *glass*.) Glass of which the sand measures a minute.

MINU'TELY. *ad.* (from *minúte*.) To a small point; exactly (*Locke*).

MI'NUTELY. *ad.* (from *mínute*, the substantive.) Every minute; with very little time intervening (*Hammond*).

MINU'TENESS. *s.* (from *minúte*.) Smallness; exility; inconsiderableness (*Bentley*).

MI'NUTE-WATCH. *s.* (*minute* and *watch*.) A watch in which minutes are more distinctly marked than in common watches which reckon by the hour (*Boyle*).

MINUTIA, a vestal virgin, accused of debauchery on account of the beauty and elegance of her dress. She was condemned to be buried alive because a female supported the false accusation, A. U. C. 418. (*Liv.*).

MINUTIUS, a name common to some eminent Romans, the most remarkable of whom is Rufus, a master of horse to the dictator Fabius Maximus. His disobedience to the commands of the dictator was productive of an extension of his prerogative, and the master of the horse was declared equal in power to the dictator. Minutius, soon after this, fought with ill success against Annibal, and was saved by the interference of Fabius; which circumstance had such an effect upon him that he laid down his power at the feet of his deliverer, and swore that he would never act but by his directions. He was killed at the battle of Cannæ.

MINUTIUS FELIX, was a famous Roman orator. He was an African; when he lived is very uncertain. The earliest date allowed him is 170; the latest 220. Dr. Lardner after Baronius supposes he lived in 210, towards the close of the reign of Septimius Severus. His defence of the christian religion is allowed to be an excellent one. It is in form of a dialogue between Cæcilius Natalis a heathen, and Octavius Januarius a christian; in which Minutius sits judge. Cæcilius first objects, and then Octavius answers. The issue is, the conviction of Cæcilius, and his conversion to christianity. This work of Minutius is a learned, ingenious, and eloquent performance. The editions most prized are that of Leyden in 1652 and 1672, of Leyden by Gronovius in 1709, the Cambridge edition of Dr. Davies, in 1712, the Glasgow edition of 1750, and the Leipsic edition of 1773.

MINX. *s.* A young, pert, wanton girl (*Shakspeare*).

MINYÆ, a name given to the inhabitants of Orchomenos, in Bœotia, from Minyas, a king of the country. Orchomenos, the son of Minyas, gave his name to the capital of the country, and the inhabitants still retained their original appellation in contradiction to the Orchomenians of Arcadia.

MINYAS, a king of Bœotia, son of Neptune and Tritegenia, the daughter of Æolus. He married Clydodora, by whom he had Presbon, Periclymenus, and Eteoclymenus. He was father of Orchomenos, Diochithondes, and Athamas, by a second marriage, with Phanasora, the daughter of Paon. According to Plutarch and Ovid he had three daughters, called Leuconoe, Alcithoe, and Leucippe. They were changed into bats. See MINEIDES.

MINYCUS, a river of Thessaly, falling into the sea near Arene, called afterwards Orchomenos.

MIOLANS, a fortress of France, in the department of the Lower Alps, seated on a craggy rock, in the valley of Barcelonetta, six miles N.E. of Montmelian. Lon. 6. 20 E. Lat. 45. 35 N.

MIOSS, a lake of Norway, in the province of Hedemarke, 80 miles in circumference. It is divided by a large peninsula, and contains a fertile island 10 miles in circumference.

MIQUELON, a small desert island, S.W. of Cape May in Newfoundland, ceded to the French in 1763, for drying and curing their fish. They were dispossessed of it by the English in 1793. Lon. 56. 10 W. Lat. 46. 42 N.

MIRA, a town of Portugal, in Beira, 16 miles N.W. of Coimbra. Lon. 8. 25 W. lat. 40. 20 N.

MIRABILE, in mineralogy, a genus of the

class salts. Of a bitter taste; not easily soluble in cold water, and the solution not made turbid by a mixture of soda; not effervescing with any acid; exposed to a white heat with powdered charcoal producing an alkaline sulphur. Four species.

1. M. genuinum. Vitriolated natrum; sulphat of soda; Glauber's salt. Of a cooling taste, easily melting in the fire, when dissolved and slowly evaporated crystallizing into very transparent unequally six-sided prisms, which moulder in the air. Found in many mineral waters of Britain and other parts of Europe, sometimes dry, rarely in a crystallized state, sometimes in a state of white efflorescence on moist walls, in vast quantities under the surface of the earth in the neighbourhood of Astracan, and in summer at the bottom of lakes, seldom found pure, but usually mixed with soda, common salt, Epsom salt, or selenite; the sides of the crystals are commonly grooved; and when exposed to a warm atmosphere they soon lose their transparency and water of crystallization, and fall into a white opake powder; when exposed to heat the salt first melts, and after the evaporation of its water becomes a white powder, which melts in a red heat. Its use as a cooling purgative is sufficiently known, for which see NATRUM VITRIOLATUM, and SULPHAT OF SODA.

2. M. potassinum. Sal polychrest; vitriolated kali; vitriolated tartar; sulphat of potass, or potash. Of a bitterish taste, decrepitating when placed on hot coals and melting in a read heat, soluble in sixteen times its weight of cold water; its crystals not mouldering in the air. With an excess of acid this salt is denominated supersulphat of potash.

Found in various parts of Spain, of a greyish white colour, and sometimes luminous in the dark; when its diluted solution is evaporated it affords six-sided prisms, or short hexangular prisms terminated by one or more hexangular pyramids; the supersulphat of potash from its excess of acid turns blue vegetable juices red, and is soluble in twice its weight of water. It was formerly used as a purgative under the name of sal polychrest; which has since been changed successively to vitriolated tartar, vitriolated kali, and now under the Lavoisierian nomenclature to sulphat of potash. For its medicinal properties, see KALI VITRIOLATUM. Specific gracity 2,298. It contains,

Acid - - - - - -	40
Potash - - - - -	52
Water - - - - -	8
	100

3. M. semivolatile. Of an acrid taste, evaporating in fumes when heated, deliquescing in the air, emitting an alkaline odour when rubbed together with quick-lime. Found rarely in the vicinity of volcanic mountains.

4. M. sulphureum. Vitriolic ammoniac; sulphat of ammonia; sulphuric acid united to ammonia. Evaporating in fumes when heated, deliquescing in the air, when rubbed together with quick-lime emitting an alkaline odour, and when sprinkled with nitric acid an odour like burnt sulphur. Found in the neighbourhood of volcanoes, in some lakes in Tuscany, at the bottom of a burning well in Dauphigny, and on the surface of the earth near Turin. It is generally found mixed with sulphur, alumina, alum, or vitriol, and hence its colour is seldom white, but of a grey, yellowish-grey, or lemon: it is found also in a stalactitical form, or investing lavas, or in an earthy state with little or no lustre: its crystals are generally six-sided prisms whose planes are unequal, terminated by six-sided pyramids: soluble in twice its weight of cold water, and slowly attracts moisture when exposed to the air; when heated it first decrepitates, and then melts, and in close vessels, sublimes. Contains,

MIRABILIS. Marble of Peru. In botany, a genus of the class pentandria, order monogynia. Corol funnel-form, superior; calyx inferior; nectary globular, inclosing the germ. Four species: natives of India and South America; the roots of one of which, M. jalapa, was formerly, but erroneously, supposed to be the officinal jalap, for which see CONVOLVULUS JALAP. The roots, however, of all these species are purgative in some degree, and are occasionally used to produce this effect. The M. jalapa is chiefly cultivated for its flowers, which are very showy and in different varieties of almost every colour.

MIRACLE, in a popular sense, is a prodigy, or an extraordinary event, that surprises us by its novelty.

MIRACLE, in a more accurate and philosophical sense, is an effect that does not follow from any of the regular laws of nature; or which is inconsistent with some known law thereof; or contrary to the settled constitution and course of things: accordingly all miracles presuppose an established system of nature, within the limits of which they operate, and with the order of which they disagree.

Spinoza denies, that any power can supersede that of nature; or that any thing can disturb, or interrupt, the order of things: and accordingly defines a miracle to be a rare event, happening in consequence of some laws that are unknown to us.

Divines define a miracle, an extraordinary and wonderful effect, above the power of nature, wrought by God, to manifest his power or providence; or to give credit to some messenger sent from himself. Thus Jesus Christ evinced the truth of his mission, and his doctrine, by miracles; and thus also did Moses. But there are scarce any theological writers that precisely agree in their definition of a miracle. Mr. Locke defines it to be a sensible operation, which, being above the comprehension of the spectator, is, in his opinion, contrary to the course of nature, and taken by him to be divine. Dr. Clarke's definition of a miracle, in the theological sense of the word, is this: that it is a work effected in a manner unusual, or different from the common and regular method of Providence, by the interposition either of God himself or of some intelligent agent superior to man, for the proof or evidence of some particular doctrine, or in attestation to the authority of some particular person. According to Dr. Sykes, a miracle is a designed effect, sensible, unusual in itself, beyond the art and power of man to do. Dr. Chandler says, that a miracle is an action done, or an operation visibly performed by any being, which is really and truly above the reach, natural power, and capacity of that being who does it, of himself, and without the assistance of some superior agent to perform. With this Dr. Hutcheson's definition nearly coincides, viz. that it is a work far exceeding human power, yet performed by the command, or upon the volition of a man. And the same writer farther observes, that, though miracles may prove the superintendency of a voluntary agent, and that the universe is not guided by necessity or fate; yet that mind must be weak and inadvertent, who needs them to confirm the belief of a wise and good Deity; since the deviation from general laws, unless upon very extraordinary occasions, must be a presumption of inconstancy and weakness rather than of a steady wisdom and power; and must weaken the best arguments we have for the sagacity and power of the universal mind.

That the visible world is governed by stated general rules, or that there is an order of causes and effects established in every part of the system of nature which falls under our observation, is a fact which cannot be controverted. If the Supreme Being, as some have supposed, be the only real agent in the universe, we have the evidence of experience, that, in the particular system to which we belong, he acts by stated rules. If he employs inferior agents to conduct the various motions from which the phenomena result, we have the same evidence that he has subjected those agents to certain fixed laws, commonly called the *laws of nature*. On either hypothesis, effects which are produced by the regular operation of these laws, or which are conformable to the established course of events, are properly called *natural*; and every contradiction to this constitution of the natural system, and the correspondent course of events in it, is called a *miracle*.

If this definition of a miracle be just, no event can be deemed miraculous merely because it is strange, or even to us unaccountable; since it may be nothing more than a regular effect of some unknown law of nature. In this country earthquakes are rare; and for monstrous births perhaps no particular and satisfactory account can be given: yet an earthquake is as regular an effect of the established laws of nature as any of those with which we are most intimately acquainted; and under circumstances in which there would always be the same kind of production, the monster is nature's genuine issue. It is therefore necessary, before we can pronounce any effect to be a true miracle, that the circumstances under which it is produced be known, and that the common course of nature be in some degree understood; for in all those cases in which we are totally ignorant of nature, it is impossible to determine what is, or what is not, a deviation from its course. Miracles, therefore, are not, as some have represented them, appeals to our ignorance. They suppose some antecedent knowledge of the course of nature, without which no proper judgment can be formed concerning them; though with it their reality may be so apparent as to prevent all possibility of a dispute.

Thus, were a physician to cure a blind man of a cataract, by anointing his eyes with a chemical preparation which we had never before seen, and to the nature and effects of which we are absolute strangers, the cure would undoubtedly be wonderful; but we could not pronounce it miraculous, because, for any thing known to us, it might be the natural effect of the operation of the unguent on the eye. But were he to recover his patient merely by commanding him to see, or by anointing his eyes with spittle, we should with the utmost confidence pronounce the cure to be a miracle; because we know perfectly that neither the human voice nor human spittle have, by the established constitution of things, any such power over the diseases of the eye. No one is now ignorant, that persons apparently dead are often restored to their families and friends, by being treated in the manner recommended by the Humane Society. To the vulgar, and sometimes even to men of science, these effects appear very wonderful; but as they are known to be produced by physical agency, they can never be considered as miraculous deviations from the laws of nature. On the other hand, no one could doubt of his having witnessed a real miracle who had seen a person that had been four days dead come alive out of his grave at the call of another, or who had even beheld a person exhibiting all the symptoms of death instantly resuscitated merely by being desired to live.

Thus easy is it, in all cases in which the course of nature is understood, to determine whether any particular event be really a miracle; whilst in circumstances where we know nothing of nature and its course, even a true miracle, were it performed, could not be admitted as such, or carry any conviction to the mind of a philosopher.

If miracles be effects contrary to the established constitution of things, we are certain that they will never be performed on trivial occasions. The constitution of things was established by the Creator and Governor of the universe, and is undoubtedly the offspring of infinite wisdom pursuing a plan for the best of purposes. From this plan no deviation can be made but by God himself, or by some powerful being acting with his permission. The plans devised by wisdom are steady in proportion to their perfection, and the plans of infinite wisdom must be absolutely perfect. From this consideration some men have ventured to conclude, that no miracle was ever wrought, or can rationally be expected; but maturer reflection must soon satisfy us that all such conclusions are hasty.

Man is unquestionably the principal creature in this world, and apparently the only one in it who is capable of being made acquainted with the relation in which he stands to his Creator. We cannot, therefore, doubt, but that such of the laws of nature as extend not their operation beyond the limits of this earth were established chiefly, if not solely, for the good of mankind; and if, in any particular circumstances, that good can be more effectually promoted by an occasional deviation from those laws, such a deviation may be reasonably expected. Were man, in the exercise of his mental and corporeal powers, subjected to the laws of physical necessity, the circumstances supposed would indeed never occur, and of course no miracle could be admitted. But such is not the nature of man.

The relation between motives and actions is different from that between cause and effect in physics; and mankind have such command over themselves, as that by their voluntary conduct they can make themselves in a great degree either happy or miserable. We know likewise from history, that, by some means or other, almost all mankind were once sunk into the grossest ignorance of the most important truths; that they knew not the Being by whom they were created and supported; that they paid divine adoration to stocks, stones, and the vilest reptiles; and that they were slaves to the most impious, cruel, and degrading superstitions.

From this depraved state it was surely not unworthy of the common "Father of all" to rescue his helpless creatures, to enlighten their understandings that they might perceive what is right, and to present to them motives of sufficient force to engage them in the practice of it. But the understandings of ignorant barbarians cannot be enlightened by arguments; because of the force of such arguments as regard moral science they are not qualified to judge. The philosophers of Athens and Rome inculcated, indeed, many excellent moral precepts, and they sometimes ventured to expose the absurdities of the reigning superstition: but their lectures had no influence upon the multitude; and they had themselves imbibed such erroneous notions respecting the attributes of the Supreme Being, and the nature of the human soul, and converted those notions into first principles, of which they would not permit an examination, that even among them a thorough reformation was not to be expected from the powers of reasoning. It is likewise to be observed, that there are many truths of the utmost importance to mankind, which unassisted reason could never have discovered. Amongst these we may confidently reckon the immortality of the soul, the terms upon which God will be reconciled to sinners, and the manner in which that all-perfect Being may be acceptably worshipped; about all of which philosophers were in such uncertainty, that, according to Plato, "Whatever is set right, and as it should be, in the present evil state of the world, can be so only by the particular interposition of God."

An immediate revelation from Heaven, therefore, was the only method by which infinite wisdom and perfect goodness could reform a bewildered and vicious race. But this revelation, at whatever time we suppose it given, must have been made directly either to some chosen individuals commissioned to instruct others, or to every man and woman for whose benefit it was ultimately intended. Were every person instructed in the knowledge of his duty by immediate inspiration, and were the motives to practise it brought home to his mind by God himself, human nature would be wholly changed: men would not be masters of their own actions; they would not be moral agents, nor by consequence be capable either of reward or of punishment. It remains, therefore, that if God has been graciously pleased to enlighten and reform mankind, without destroying that moral nature which is essential to virtue, he can have done it only by revealing his truth to certain chosen instruments, who were the immediate instructors of their contemporaries, and through them have been the instructors of succeeding ages.

Let us suppose this to have been actually the case, and consider how those inspired teachers could communicate to others every truth which had been revealed to themselves. They might easily, if it were part of their duty, deliver a sublime system of natural and moral science, and establish it upon the common basis of experiment and demonstration; but what foundation could they lay for those truths which unassisted reason cannot discover, and which, when they are revealed, appear to have no necessary relation to any thing previously known? To a bare affirmation that they had been immediately received from God, no rational being could be expected to assent. The teachers might be men of known veracity, whose simple assertion would be admitted as sufficient evidence for any fact, in conformity with the laws of nature; but as every man has the evidence of his own consciousness and experience that revelations from heaven are deviations from these laws, an assertion so apparently extravagant would be rejected as false, unless supported by some better proof than the mere affirmation of the teacher. In this state of things, we can conceive no evidence sufficient to make such doctrines be received as the truths of God, but the power of working miracles committed to him who taught them. This would, indeed, be fully adequate to the purpose. For, if there were nothing in the doctrines themselves impious, immoral, or contrary to truths already known, the only thing which could render the teacher's assertion incredible, would be its implying such an intimate communion with God as is contrary to the established course of things, by which men are left to acquire all their knowledge by the exercise of their own faculties.—Let us now suppose some of those inspired teachers to tell his countrymen, that he did not desire them, on his *ipse dixit*, to believe that he had any preternatural communion with the Deity, but that for the truth of his assertion he would give them the evidence of their own senses; and after this declaration let us suppose him immediately to raise a person from the dead in their presence, merely by calling upon him to come out of his grave. Would not the only possible objection to the man's veracity be removed by this miracle? and his assertion that he had received such and such doctrines from God be as fully credited as if it related to the most common occurrence? Undoubtedly it would; for, when so much preternatural power was visibly communicated to this person, no one could have reason to question his having received an equal portion of preternatural knowledge. A palpable deviation from the known laws of nature, in one instance, is a sensible proof that such a deviation is possible in another; and in such a case as this it is the witness of God to the truth of a man.

Miracles, then, under which we include prophecy, are the only direct evidence which can be given of divine inspiration. When a religion, or any religious truth, is to be revealed from heaven, they appear to be absolutely necessary to enforce its reception among men; and this is the only case in which we can suppose them necessary, or believe for a moment that they ever have been or will be performed.

The history of almost every religion abounds with relations of prodigies and wonders, and of the intercourse of men with the gods; but we know of no religious system, those of the Jews and Christians excepted, which appealed to miracles as the sole evidence of its truth and divinity. The pretended miracles mentioned by Pagan historians and poets are not said to have been publicly wrought to enforce the truth of a new religion contrary to the reigning idolatry. Many of them may be clearly shown to have been mere natural events. Others are represented as having been performed in secret on the most trivial occasions, and in obscure and fabulous ages long prior to the era of the writers by whom they are recorded. And such of them as at first view appear to be best attested, are evidently tricks contrived for interested purposes; to flatter power, or to promote the prevailing superstitions. For these reasons, as well as on account of the immoral character of the divinities by whom they are said to have been wrought, they are altogether unworthy of examination, and carry in the very nature of them the completest proofs of falsehood and imposture.

But the miracles recorded of Moses and of Christ bear a very different character. None of them is represented as wrought on trivial occasions. The writers who mention them were eyewitnesses of the facts; which they affirm to have been performed publicly, in attestation of the truth of their respective systems. They are indeed so incorporated with these systems, that *the miracles cannot be separated from the doctrines; and if the miracles were not really performed, the doctrines cannot possibly be true.* Besides all this, they were wrought in support of revelations which opposed all the religious systems, superstitions, and prejudices, of the age in which they were given: a circumstance which of itself sets them, in point of authority, infinitely above the Pagan prodigies, as well as the lying wonders of the Romish church.

It is indeed, we believe, universally admitted, that the miracles mentioned in the book of Exodus and in the four Gospels, might, to those who saw them performed, be sufficient evidence of the divine inspiration of Moses and of Christ; but to us it may be thought that they are no evidence whatever, as we must believe in the miracles themselves, if we believe in them at all, upon the bare authority of human testimony. Why, it has been sometimes asked, are not miracles wrought in all ages and countries? If the religion of Christ were to be of perpetual duration, every generation of men ought to have complete evidence of its truth and divinity.

To the performance of miracles in every age and in every country, perhaps the same objections lie as to the immediate inspiration of every individual. Were those miracles universally received as such, men would be so overwhelmed with the nature rather than with the force of their authority, as hardly to remain masters of their own conduct; and in that case the very end of all miracles would be defeated by their frequency. The truth, however, seems to be, that miracles so frequently repeated would not be received as such, and of course would have no authority; because it would be difficult, and in many cases impossible, to distinguish them from natural events. If they recurred regularly at certain intervals, we could not prove them to be deviations from the known laws of nature, because we should have the same experience for the one series of events as for the other; for the regular succession of preternatural effects, as for the established constitution and course of things.

Be this, however, as it may, we shall take the liberty to affirm, that for the reality of the Gospel miracles we have evidence as convincing to the reflecting mind, though not so striking to vulgar apprehension, as those had who were contemporary with Christ and his apostles, and actually saw the mighty works which he performed. To the admirers of Mr. Hume's philosophy this assertion will appear an extravagant paradox; but we hope to demonstrate its truth from principles which, consistently with himself, that author could not have denied. He has indeed endeavoured to prove, that "no testimony is sufficient to establish a miracle;" and the reasoning employed for this purpose is, that "a miracle being a violation of the laws of nature, which a firm and unalterable experience has established, the proof against a miracle, from the very nature of the fact, is as entire as any argument from experience can be; whereas our experience of human veracity, which (according to him) is the sole foundation of the evidence of testimony, is far from being uniform, and can therefore never preponderate against that experience which admits of no exception." This boasted and plausible argument has with equal candour and acuteness been examined by Dr. Campbell; who justly observes, that so far is experience from being the sole foundation of the evidence of testimony, that, on the contrary, testimony is the sole foundation of by far the greater part of what Mr. Hume calls firm and unalterable experience; and that if in certain circumstances we did not give an implicit faith to testimony, our knowledge of events would be confined to those which had fallen under the immediate observation of our own senses. See ABRIDGEMENT.

But though Dr. Campbell has exposed the sophistry of his opponent's reasoning, and overturned the principles from which he reasons, we are persuaded that he might safely have joined issue with him upon those very principles. To us, at least, it appears that the testimony upon which we receive the Gospel miracles is precisely of that kind which Mr. Hume has acknowledged sufficient to establish even a miracle. "No testimony (says he) is sufficient to establish a miracle, unless the testimony be of such a kind that its falsehood would be more miraculous than the fact which it endeavours to establish. When one tells me that he saw a dead man restored to life, I immediately consider with myself whether it be more probable that this person should either deceive or be deceived, or that the fact which he relates should really have happened. I weigh the one miracle against the other; and according to the superiority which I discover I pronounce my decision, and always reject the greater miracle." In this passage every reader may remark, what did not escape the perspicacious eye of Dr. Campbell, a strange confusion of terms: but as all miracles are equally easy to the Almighty; and, as Mr. Hume has elsewhere observed, that "the raising of a feather, when the wind wants ever so little of a force requisite for that purpose, is as real a miracle as the raising of a house or a ship into the air;" candour obliges us to suppose, that by talking of greater and less miracles, and of always rejecting the greater, he meant nothing more, but that of two deviations from the known laws of nature he always rejects that which in itself is least probable.

If then we can shew that the testimony given by the apostles and other first preachers of Christianity to the miracles of their Master would, upon the supposition that those miracles were not really performed, have been as great a deviation from the known laws of nature as the miracles themselves, the balance must be considered as evenly poised by opposite miracles; and whilst it continues so, the judgment must remain in a state of suspense. But if it shall appear, that in this case the false testimony would have been a deviation from the laws of nature less probable in itself than the miracles recorded in the Gospels, the balance will be instantly destroyed; and by Mr. Hume's maxim we shall be obliged to reject the supposition of falsehood in the testimony of the apostles, and admit the miracles of Christ to have been really performed.

In this argument we need not waste time in proving that those miracles, as they are represented in the writings of the New Testament, were of such a nature, and performed before so many witnesses, that no imposition could possibly be practised on the senses of those who affirm that they were present. From every page of the Gospels this is so evident, that the philosophical adversaries of the Christian faith never suppose the apostles to have been themselves deceived, but boldly accuse them of bearing false witness. But if this accusation be well founded, their testimony itself is as great a miracle as any which they record of themselves or of their Master.

Ideas and relations are in the mind of every man so closely associated with the words by which they are expressed in his native tongue, and in every other language of which he is master, that the one cannot be entirely separated from the other; and therefore no man can on any occasion speak falsehood without some effort; by no effort can a man give consistency to an unpremeditated detail of falsehood, if it be of any length, and include a number of particulars; and it is still less possible for several men to agree in such a detail, when at a distance from each other, and cross-questioned by their enemies.

This being the case, it follows, if the testimony of the apostles to their own and their Master's miracles be false, either that they must have concerted a consistent scheme of falsehood, and agreed to publish it at every hazard; or that God, or some powerful agent appointed by him, must have dissolved all the associations formed in their minds between ideas of sense and the words of language, and arbitrarily formed new associations, all in exact conformity to each other, but all in direct contradiction to truth. One or other of these events must have taken place; because, upon the supposition of falsehood, there is no other alternative. But such a dissolution and formation of associations as the latter implies, must, to every man who shall attentively consider it, appear to be as real a miracle, and to require as great an exertion of power, as the resurrection of the dead. Nor is the supposed voluntary agreement of the apostles in a scheme of falsehood an event less miraculous. When they sat down to fabricate their pretended revelation, and to contrive a series of miracles to which they were unanimously to appeal for its truth, it is plain, since they proved successful in their daring enterprise, that they must have clearly foreseen every possible circumstance in which they could be placed, and have prepared consistent answers to every question that could be put to them by their most inveterate and most enlightened enemies; by the statesman, the lawyer, the philosopher, and the priest. That such foreknowledge as this would have been miraculous will not surely be denied; since it forms the very attribute which we find it most difficult to allow even to God himself. It is not, however, the only miracle which this supposition would compel us to swallow. The very resolution of the apostles to propagate the belief of false miracles in support of such a religion as that which is taught in the New Testament, is as great a miracle as human imagination can easily conceive.

When they formed this design, either they must have hoped to succeed, or they must have foreseen that they should fail in their undertaking; and in either case, they chose evil for its own sake. They could not, if they foresaw that they should fail, look for any thing but that contempt, disgrace, and persecution, which were then the inevitable consequences of an unsuccessful endeavour to overthrow the established religion. Nor could their prospects be brighter upon the supposition of their success. As they knew themselves to be false witnesses and impious deceivers, they could have no hopes beyond the grave; and by determining to oppose all the religious systems, superstitions, and prejudices of the age in which they lived, they wilfully exposed themselves to inevitable misery in the present life, to insult and imprisonment, to stripes and death. Nor can it be said that they might look forward to power and affluence when they should, through sufferings, have converted their countrymen; for so desirous were they of obtaining nothing but misery as the end of their mission, that they made their own persecution a test of the truth of their doctrines. They introduced the Master, from whom they pretended to have received these doctrines, as telling them that "they were sent forth as sheep in the midst of wolves; that they should be delivered up to councils, and scourged in synagogues; that they should be hated of all men for his name's sake; that the brother should deliver up the brother to death, and the father the child; and that he who took not up his cross and followed after him was not worthy of him." The very system of religion, therefore, which they invented and resolved to impose upon mankind, was so contrived, that the worldly prosperity of its first preachers, and even their exemption from persecution, was incompatible with its success. Had these clear predictions of the Author of that religion, under whom the apostles acted only as ministers, not been verified, all mankind must have instantly perceived that their pretence to inspiration was false, and that Christianity was a scandalous and impudent imposture. All this the apostles could not but foresee when they formed their plan for deluding the world. Whence it follows, that when they resolved to support their pretended revelation by an appeal to forged miracles, they wilfully and with their eyes open exposed themselves to inevitable misery, whether they should succeed or fail in their enterprise; and that they concerted their measures so as not to admit of a possibility of recompense to themselves, either in this life or in that which is to come. But if there be a law of nature, for the reality of which we have better evidence than we have for others, it is, "that no man can choose misery for its own sake," or make the acquisition of it the ultimate end of his pursuit. The existence of other laws of nature we know by testimony and our own observation of the regularity of their effects. The existence of this law is made known to us not only by these means, but also by the still clearer and more conclusive evidence of our own consciousness.

Thus, then, do miracles force themselves upon our assent in every possible view which we can take of this interesting subject. If the testimony of the first preachers of Christianity was true, the miracles recorded in the Gospel were certainly performed, and the doctrines of our religion are derived from heaven. On the other hand, if that testimony was false, either God must have miraculously effaced from the minds of those by whom it was given all the associations formed between their sensible ideas and the words of language, or he must have endowed those men with the gift of prescience, and have impelled them to fabricate a pretended revelation for the purpose of deceiving the world, and involving themselves in certain and foreseen destruction.

The power necessary to perform the one series of these miracles may, for any thing known to us, be as great as that which would be requisite for the performance of the other; and considered merely as exertions of preternatural power, they may seem to balance each other, and to hold the mind in a state of suspense. But when we take into consideration the different purposes for which these opposite and contending miracles were wrought, the balance is instantly destroyed. The miracles recorded in the Gospels, if real, were wrought in support of a revelation which, in the opinion of all by whom it is received, has brought to light many important truths which could not otherwise have been made known to men; and which, by the confession of its adversaries, contains the purest moral precepts by which the conduct of mankind was ever directed. The opposite series of miracles, if real, was performed to enable, and even to compel, a company of Jews, of the lowest rank and of the narrowest education, to fabricate, with the view of inevitable destruction to themselves, a consistent scheme of falsehood, and by an appeal to forged miracles to impose it upon the world as a revelation from heaven. The object of the former miracles is worthy of a God of infinite wisdom, goodness, and power. The object of the latter is absolutely inconsistent with wisdom and goodness, which are demonstrably attributes of that Being by whom alone miracles can be performed. Whence it follows, that the supposition of the apostles bearing *false* testimony to the miracles of their Master, implies a series of deviations from the laws of nature infinitely less probable in themselves than those miracles: and therefore, by Mr. Hume's maxim, we must necessarily reject the supposition of falsehood in the testimony, and admit the reality of the miracles. So true is it, that for the reality of the Gospel-miracles we have evidence as convincing to the reflecting mind, as those had who were contemporary with Christ and his apostles, and were actual witnesses to their mighty works.

As much of the discussion relative to miracles, according to the channel into which it has been thrown by Mr. Hume and his disciples, is made to turn upon the phrase "laws of nature;" we must not forget to remark that in this enquiry, nothing can consistently be meant by the laws of nature but those laws by which both the *moral* and *physical* worlds are governed; and that since this question respects altogether the *moral* government of God, the *moral* laws of nature ought here to fall principally under consideration. This consideration, however, is totally lost sight of, and the physical laws alone regarded by Mr. Hume in estimating the credibility of miracles; which is just as absurd as it would be to refer solely to the laws of contracts, oaths, and promises, the criteria of virtue and vice, and other moral principles, in order to investigate a correct and unobjectionable theory of *physical astronomy*.

Considered, then, in this point of view, it is evident that the extraordinary nature of the fact is no ground for disbelief, provided such a fact *morally* contemplated, was from the condition of man become necessary; for in that case, the Deity, by dispensing his assistance in proportion to our wants, acted upon the same principle as in his more ordinary occupations. For whatever the *physical* effects may be, if their *moral* tendency be the same, they form a part of the same moral law. Now in the events called miraculous, the Deity *is* influenced by the same moral principle as in his usual dispensations; and being induced by the same motive to accomplish the same end, the laws of God's moral government are not violated, such laws being established by the *motives* and the *ends produced*, and not by the *means employed*. In estimating, therefore, the credibility of a miracle, we look at the *moral* not the *physical* effect; and it is on this account that every unbiassed mind is compelled almost antecedent to any enquiry to reject most of the pretended miracles of the Romish church. But estimating the miracles of the apostolic age by this criterion, there cannot be found the shadow of a reason for rejecting them.

In this enquiry, too, it ought not to be forgotten that many of the first adversaries of our religion, and those the most formidable, never disputed the truth and reality of miracles; on the contrary, they mention them as having been performed. The Jews themselves acknowledged their reality. Julian and Celsus, two avowed enemies of Christianity, amongst all the arts which they used to destroy its credibility, ventured not to deny that our Saviour and his apostles wrought miracles; but ascribed them to magic. Facts confessed by those who had the greatest interest in denying them, ought to be admitted. But such is the hardihood of unbelief, such the impenetrability of the mind, when conviction must lead to an abandonment of practical as well as mental error, that our modern infidels deny what the first unbelievers with all *their superior* means of information found themselves obliged to admit. See farther the articles ABRIDGEMENT, CELSUS, CHRISTIANITY, CREDIBILITY, JULIAN, PORPHYRY, &c.

MIRA'CULOUS. *a.* (*miraculeux*, French.) Done by miracle; produced by miracle; effected by power more than natural (*Herbert*).

MIRA'CULOUSLY. *ad.* By miracle; by power above that of nature (*Dryden*).

MIRA'CULOUSNESS. *s.* (from *miraculous.*) The state of being effected by miracle; superiority to natural power.

MIRADO'R. *s.* (Spanish, from *mirar*, to look.) A balcony (*Dryden*).

MIRANDA DO CORVO, a town of Portugal, in Beira, 15 miles S. E. of Coimbra. Lon. 8. 10 W. Lat. 40. 2 N.

MIRANDA DE EBRO, a town of Old Castile, in Spain, 34 miles S. of Bilboa. Lat. 42. 49 N. Lon. 3. 10 W.

MIRANDE, a town of Gascony, in France. Lat. 43. 30 N. Lon. 0. 26 E.

MIRANDO DE DOURO, the capital of Tra los Montes, in Portugal. It is the see of a bishop, is well fortified, and is 37 miles

N.W. of Salamanca. Lat. 41. 40 N. Lon. 6. 0 W.

MIRANDOLA, the capital of a duchy of the same name in Italy. It was taken by the king of Sardinia in 1742. It is 20 miles N.E. of Modena. Lat. 44. 52 N. Lon. 11. 19 E.

MIRANDULA. See PICUS.

MIRE. *s.* (*moer*, Dutch.) Mud; dirt at the bottom of water (*Roscommon*).

To MIRE. *v. a.* (from the noun.) To whelm in the mud; to soil with mud (*Shakspeare*).

MIRE. *s.* (myꝛa, Sax. *mier*, Dutch.) An ant; a pismire.

MI'RINESS. *s.* (from *miry*.) Dirtiness; fulness of mire.

MI'RKSOME, *a.* Dark; obscure (*Spenser*).

MIRROUR, in catoptrics, any polished body impervious to the rays of light, and which reflects them equally.

Mirrours were anciently made of metal; but, at present, they are generally smooth plates of glass, tinned or quicksilvered on the back part, and called looking-glasses. The doctrine of mirrours depends wholly on that fundamental law, that the angle of reflection is always equal to the angle of incidence. See OPTICS.

Parallel rays falling directly on a plane speculum are reflected back upon themselves; if they fall obliquely, they are reflected in the same angle, and parallel as they fell. Hence there is no such thing, properly speaking, as a focus belonging to a plane speculum, neither real nor virtual. The focus of parallel rays is called the solar focus; because in that the image of the sun is formed, and of all objects very remote. But the focus of any object situated near the mirrour, will have its distance from the vertex more or less than half the radius; the rule in all cases being as follows: "Multiply the distance of the object into the radius of the mirrour, and divide the product by the sum of the radius, and twice the distance of the object; the quotient will be the focal distance of a convex mirrour."

Again, for a concave mirrour, the same product of the radius into the distance of the object, divided by the difference of radius and twice the distance of the object, will give the focal distance. And here we are to observe, that, as twice the distance of the object is lesser or greater than the radius, so the focus will be positive or negative, that is, behind the glass or before it.

The image of the object is formed in the focus proper to its distance, and, since the writers on optics demonstrate that the angles under which the object and its image are seen from the centre or vertex of the mirrour are always equal, it follows, that the image will be always in proportion to the object, as the focal distance to the object's distance. The position of the object will be always erect at a positive focus, or behind the speculum diminished by a convex, and magnified by a concave one. Hence, since a convex has but one, viz. an affirmative focus; so it can never magnify any object, howsoever posited before it.

The position of the image in a negative focus, or that before the glass, will be ever inverted; and, if nearer the vertex than the centre, it will be less; if further from it, it will be greater than the object; but in the centre it will be equal to the object, and seen to touch it.

The image formed by a plane speculum is erect, large as the life, at the same apparent distance behind the glass as the object is before it, and on the same side of the glass with the object. Those properties render this sort of mirrour of most common use, viz. as a looking-glass.

If the rays fall directly, or nearly so, on a plane mirrour, and the object be opaque, there will be but one single image formed, or at least be visible, and that by the second surface of the speculum, and not by the first, through which the rays do most of them pass.

But if the object be luminous, and the rays fall very obliquely on the speculum, there will be more than one image formed to an eye placed in a proper position to view them. The first image being formed by the first surface, will not be so bright as the second, which is formed by the second surface. The third, fourth, &c. images are produced by several reflections of the rays between the two surfaces of the speculum; and, since some light is lost by each reflection, the images from the second will appear still more faint and obscure to the eighth, ninth, or tenth, which can scarcely be discerned at all.

Mirrours may be divided into plane, concave, convex, cylindrical, conical, parabolical, and elliptical.

The properties of cylindrical mirrours are, 1. The dimensions of objects corresponding lengthwise to the mirrour are not much changed; but those corresponding breadthwise have their figures altered, and their dimensions lessened the further from the mirrour; whence arises a very great distortion. 2. If the plane of the reflection cut the cylindric mirrour through the axis, the reflection is performed in the same manner as in a plane mirrour; and if parallel to the base, the reflection is the same as in a spherical mirrour; if it cut it obliquely, the reflection is the same as in an elliptic mirrour. Hence, as the plane of reflection never passes through the axis of the mirrour, except when the eye and objective line are in the same plane; nor parallel to the base, except when the radiant point and the eye are at the same height; the reflection is therefore usually the same as in an elliptic one. 3. If a hollow cylindric mirrour be directly opposed to the sun, instead of a focus of a point, the rays will be reflected into a lucid line parallel to its axis, at a distance somewhat less than a fourth of its diameter. Hence arises a method of drawing anamorphoses, that is, wild deformed figures on a plane, which appear well proportioned when viewed in a cylindric mirrour.

In an elliptic mirrour, if a ray strike on it from one of its focuses, it is reflected into the other. Parabolic mirrours (such, we mean, as are in the form of hollow paraboloids) as all the rays they reflect meet in one point, make the best burning-glasses.

MIRTH. *s.* (myꞃhðe, Saxon.) Merriment; jollity; gayety; laughter (*Pope*).

MI'RTHFUL. *a.* (*mirth* and *full.*) Merry, gay; cheerful (*Ben Jonson*).

MI'RTHLESS. *a.* (from *mirth.*) Joyless; cheerless.

MI'RY. *a.* (from *mire.*) 1. Deep in mud; muddy (*Temple*). 2. Consisting of mire (*Shakspeare*).

MIS, an inseparable particle used in composition to mark an ill sense, or depravation of the meaning: as *chance*, luck; *mischance*, ill luck; from *mes*, French, used in the same sense.

MISACCEPTA'TION. *s.* (*mis* and *acceptation.*) The act of taking in a wrong sense.

MISADVEN'TURE. *s.* (*misadventure*, Fr.) Mischance; misfortune; ill luck (*Clarendon*).

MISADVE'NTURED. *a.* (from *misadventure.*) Unfortunate (*Shakspeare*).

MISADVI'SED. *a.* (*mis* and *advised.*) Ill directed.

MISA'IMED. *a.* (*mis* and *aim.*) Not aimed rightly (*Spenser*).

MI'SANTHROPE. MISA'NTHROPOS. *s.* (*misanthrope*, Fr. μισανθρωπος.) A hater of mankind (*Shakspeare*).

MISA'NTHROPY. *s.* (*misanthropie*, Fr.) Hatred of mankind.

MISAPPLICA'TION. *s.* (*mis* and *application.*) Application to a wrong purpose (*Brown*).

To MISAPPLY'. *v. a.* (*mis* and *apply.*) To apply to wrong purposes (*Howel*).

To MISAPPREHE'ND. *v. a.* (*mis* and *apprehend.*) Not to understand rightly (*Locke*).

MISAPPREHE'NSION. *s.* (*mis* and *apprehension.*) Mistake; not right apprehension.

To MISASCRI'BE. *v. a.* (*mis* and *ascribe.*) To ascribe falsely (*Boyle*).

To MISASSI'GN. *v. a.* (*mis* and *assign.*) To assign erroneously (*Boyle*).

To MISBECO'ME. *v. a.* (*mis* and *become.*) Not to become; to be unseemly; not to suit (*Sidney*).

MISBEGOT. MISBEGO'TTEN. *a.* (*begot* or *begotten* with *mis.*) Unlawfully or irregularly begotten (*Dryden*).

To MISBEHA'VE. *v. n.* (*mis* and *behave.*) To act ill or improperly (*Young*).

MISBEHA'VED. *a.* (*mis* and *behaved.*) Untaught; ill-bred; uncivil (*Shakspeare*).

MISBEHA'VIOUR. *s.* (*mis* and *behaviour.*) Ill conduct; bad practice (*Addison*).

MISBELI'EF. *s.* (*mis* and *belief.*) False religion; a wrong belief.

MISBELI'EVER. *s.* (*mis* and *believer.*) One that holds a false religion, or believes wrongly (*Dryden*).

To MISCA'L. *v. a.* (*mis* and *call.*) To name improperly (*Glanville*)

To MISCA'LCULATE. *v. a.* (*mis* and *calculate.*) To reckon wrong (*Arbuthnot*).

MISCA'RRIAGE. *s.* (*mis* and *carriage.*) 1. Unhappy event of an undertaking; failure, ill conduct (*Rogers*). 2. Abortion; act of bringing forth before the time (*Graunt*).

To MISCA'RRY. *v. n.* (*mis* and *carry.*) 1. To fail; not to have the intended event; not to succeed (*Shakspeare*). 2. To have an abortion (*Pope*).

To MISCA'ST. *v. a.* (*mis* and *cast.*) To take a wrong account of (*Brown*).

MISCELLA'NE. *s.* (*miscellaneus*, Latin.) Mixed corn: as, wheat and rye (*Bacon*).

MISCELLA'NEOUS. *a.* (*miscellaneus*, Lat.) Mingled; composed of various kinds (*Brown*).

MISCELLANEÆ, in botany, the name of the fifty-fourth order in Linnæus's Fragments of a Natural Method, consisting of plants, which not being connected together by numerous relations, in their habit and structure, as the natural families, are assembled into one head, under the general title of miscellaneous plants.

MISCELLA'NEOUSNESS. *s.* (from *miscellaneous.*) Composition of various kinds.

MI'SCELLANY. *a.* (*miscellaneus*, Latin.) Mixed of various kinds (*Bacon*).

M'ISCELLANY. *s.* A mass formed out of various kinds (*Pope*).

MISCHA'NCE. *s.* (*mis* and *chance.*) Ill luck; ill fortune; misfortune; mishap (*South*).

MI'SCHIEF. *s.* (*meschef*, old French.) 1. Harm; hurt; whatever is ill and injuriously done (*Rowe*). 2. Ill consequence; vexatious affair (*Swift*).

To MI'SCHIEF. *v. a.* (from the noun.) To hurt; to harm; to injure (*Sprat*).

MI'SCHIEFMAKER. *s.* (from *mischief* and *make.*) One who causes mischief.

MI'SCHIEVOUS. *a.* (from *mischief.*) 1. Harmful; hurtful; destructive; noxious; pernicious; injurious; wicked (*South*). 2. Spiteful; malicious (*Ainsworth*).

MI'SCHIEVOUSLY. *ad.* Noxiously; hurtfully; wickedly (*Dryden*).

MI'SCHIEVOUSNESS. *s.* Hurtfulness; perniciousness; wickedness (*South*).

MISCHNA, or MISNA, from שנה, *iteravit*, a part of the Jewish Talmud.

The Mischna contains the text; and the Gemara, which is the second part of the Talmud, contains the commentaries; so that the Gemara is, as it were, a glossary on the Mischna.

The Mischna consists of various traditions of the Jews, and of explanations of several passages of scripture: these traditions, serving as an explication of the written law, and supplement to it, are said to have been delivered to Moses during the time of his abode on the mount; which he afterwards communicated to Aaron, Eleazer, and his servant Joshua. By these they were transmitted to the seventy elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wise men of Jerusalem and Babylon received them. According to Prideaux's account, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Just; who delivered them to Antigonus of Socho; and from him they came down in regular succession to Simeon, who took our Saviour in his arms; Gamaliel, at whose feet Paul was educated; and last of all to Rabbi Judah the Holy, who committed them to writing in the Mischna. But Dr. Prideaux rejecting this Jewish fiction, observes, that after the death of Simon the Just, about two hundred and ninety-two years before Christ, the Mischnical doctors arose, who, by their comments and conclusions, added to the number of those traditions which had been received and allowed by Ezra, and the men of the great synagogue; so that towards the middle of the second century, after Christ, under the empire of Antoninus Pius, it was found necessary to commit these traditions to writing; more especially as their country had considerably suffered under Adrian, and many of their schools had been dissolved, and their learned men cut off; and, therefore, the usual method of preserving their traditions had failed. Rabbi Judah, on this occasion, being rector of the school at Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of sixty-three. (Prid. Connect. vol. ii. p. 468, &c. ed. 9.) This learned author computes that the Mischna was composed about the 150th year of our Lord; but Dr. Lightfoot says, that Rabbi Judah compiled the Mischna about the year of Christ 190, in the latter end of the reign of Commodus; or, as some compute, in the year of Christ 220. Dr. Lardner is of opinion that this work could not have been finished before the year 190, or later. (Collect. of Jewish and Heathen Testimonies, &c. vol. i. p. 178.) Thus the book called the Mischna was formed; a book which the Jews have generally received with the greatest veneration. The original has been published, with a Latin translation, by Surenhusius, with notes of his own, and others from the learned Maimonides, &c. in 6 vols. fol. Amsterdam, A. D. 1698—1703. See Talmud.

It is written in a much purer style, and is not near so full of dreams and visions as the Gemara.

MI'SCIBLE. *a.* (from *misceo*, Lat.) Possible to be mingled (*Arbuthnot*).

MISCITA'TION. *s.* (*mis* and *citation.*) Unfair or false quotation (*Collier*).

To MISCI'TE. *v. a.* (*mis* and *cite.*) To quote wrong.

MISCLA'IM. *s.* (*mis* and *claim.*) Mistaken claim (*Bacon*).

MISCOMPUTA'TION. *s.* (*mis* and *computation.*) False reckoning (*Clarendon*).

MISCONCE'IT. Misconce'ption. *s.* (*mis* and *conceit*, and *conception.*) False opinion; wrong notion (*Hooker*).

MISCONCE'IVE. *v. a.* (*mis* and *conceive.*) To misjudge; to have a false notion of (*Shak.*).

MISCO'NDUCT. *s.* (*mis* and *conduct.*) Ill behaviour; ill management (*Rogers*).

To Miscondu'ct. *v. a.* (*mis* and *conduct.*) To manage amiss; to carry on wrong.

MISCONJE'CTURE. *s.* (*mis* and *conjecture.*) A wrong guess (*Brown*).

MISCONSTRU'CTION. *s.* (*mis* and *construction.*) Wrong interpretation of words or things.

To MISCO'NSTRUE. *v. a.* (*mis* and *construe.*) To interpret wrong (*Raleigh*).

To MISCO'UNT. *v. a.* (*mescounter*, Fr. *mis* and *count.*) To reckon wrong (*Shak.*).

MI'SCREANCE. Mi'screancy. *s.* (from *mescreance*, French.) Unbelief; false faith; adherence to a false religion (*Swift*).

MI'SCREANT. *s.* (*mescreant*, French.) 1. One that holds a false faith; one who believes in false gods (*Hooker*). 2. A vile wretch (*Addison*).

MISCREA'TE. Miscrea'ted. *a.* (*mis* and *create.*) Formed unnaturally or illegitimately; made as by a blunder of nature (*Shakspeare*).

MISDE'ED. *s.* (*mis* and *deed.*) Evil action. (*Shakspeare*).

To MISDE'EM. *v. a.* (*mis* and *deem.*) To judge ill of; to mistake (*Davies*).

To MISDEME'AN. *v. a.* (*mis* and *demean.*) To behave ill (*Shakspeare*).

MISDEME'ANOUR, an offence, or fault, particularly when in the execution of an office.

A crime, or misdemeanour, says judge Blackstone, is an act committed, or omitted, in violation of a public law, either forbidding or commanding it. This general definition comprehends both crimes and misdemeanours; which, properly speaking, are mere synonymous terms; though, in common usage, the word *crimes* is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprized under the gentler name of misdemeanours only.

High crimes and misdemeanours denote offences of a heinous nature, next to high treason.

To MISDO'. *v. a.* (*mis* and *do.*) To do wrong; to commit a crime (*Milton*).

To Misdo'. *v. n.* To commit faults (*Dryden*).

MISDO'ER. *s.* (from *misdo.*) An offender; a criminal; a malefactor (*Spenser*).

MISDO'ING. *s.* (from *misdo.*) Offence; deviation from right (*L'Estrange*).

To MISDO'UBT. *v. a.* (*mis* and *doubt.*) To suspect of deceit or danger (*Dryden*).

Misdo'ubt. *s.* (*mis* and *doubt.*) 1. Suspicion of crime or danger (*Shakspeare*). 2. Irresolution; hesitation (*Shakspeare*).

MISE, a French term, literally denoting expence, or disbursement: it is used in our law-books in divers acceptations. Sometimes for the profits of lands; sometimes for taxes, or taillages; and sometimes for expences, or costs: as, *pro misis et custagiis*, for costs and charges in the entries of judgments, &c.

Mise more peculiarly denotes an honorary gift, or customary present, wherewith the people of Wales used to salute every new king and prince of Wales at their entrance upon the principality.

Anciently, the mise was given in cattle, wine, corn, &c. for the support of the prince's family; but when that dominion was annexed to the English crown, the gift was changed into money. The county of Flint paid two thousand marks, &c. for their mise.

The county of Chester also paid a mise or tribute of five thousand marks at the change of every owner of the said earldom, for enjoying the privileges of that palatinate. At Chester they have a mise-book, wherein every town and village in the county is rated what to pay towards the mise.

Mise is also used in speaking of a writ of right. What in other actions is called an issue, in a writ of right is called a mise or me: so that to join the mise upon the meer, is as much as to say, to join issue on the meer right, i. e. to join upon this point, whether has the more right, the tenant or demandant.

Yet even in a writ of right, if a collateral point be tried, it is there called an issue, not a mise.

Mise is also sometimes used corruptly for mease, a messuage or tenement.

To MISEMPLO'Y. *v. a.* (*mis* and *employ.*) To use to wrong purposes (*Atterbury*).

MISEMPLO'YMENT. *s.* (*mis* and *employment.*) Improper application (*Hale*).

MISEN, Misson, or Mizen, in a ship, denotes either the mast, or sail of that name; but at sea they always mean the sail when the word misen is used.

This is the hindmost of the fixed sails of a ship, extended sometimes by a gaff, and sometimes by a yard, which crosses the mast obliquely.

MI'SER. *s.* (*miser*, Latin.) 1. A wretched person: not in use (*Sidney*). 2. A wretch; a mean fellow: not in use (*Shakspeare*). 3. A wretch covetous to extremity (*Otway*).

MI'SERABLE. *a.* (*miserable*, French.) 1. Unhappy; calamitous; wretched (*South*). 2. Wretched; worthless (*Job*). 3. Culpably parsimonious; stingy.

MI'SERABLENESS. *s.* (from *miserable.*) State of misery.

MI'SERABLY. *ad.* (from *miserable.*) 1. Unhappily; calamitously (*South*). 2. Wretchedly; meanly (*Sidney*). 3. Covetously (*Ainsworth*).

MI'SERY. *s.* (*miseria*, Latin.) 1. Wretchedness; unhappiness (*Locke*). 2. Calamity; misfortune (*Shakspeare*). 3. (from *miser.*) Covetousness; avarice (*Wotton*).

To MISFA'SHION. *v. a.* (*mis* and *fashion.*) To form wrong (*Hakewill*).

MISFO'RTUNE. *s.* (*mis* and *fortune.*) Calamity; ill luck; want of good fortune (*Addison*).

To MISGI'VE. *v. a.* (*mis* and *give.*) To fill with doubt; deprive of confidence (*Shak.*).

To MISGO'VERN. *v. a.* (*mis* and *govern.*) To govern ill; to administer unfaithfully (*Kn.*).

MISGO'VERNMENT. *s.* 1. Ill administration of public affairs (*Ral.*). 2. Ill management (*Taylor*). 3. Irregularity; inordinate behaviour (*Shakspeare*).

MISGUI'DANCE. *s.* (*mis* and *guidance.*) False direction (*South*).

To MISGUI'DE. *v. a.* (*mis* and *guide.*) To direct ill; to lead the wrong way (*Locke*).

MISHA'P. *s.* (*mis* and *hap.*) Ill chance; ill luck; calamity (*Spenser*).

MI'SHMASH. *s. Ains.* A low word. A mingle.

To MISINFE'R. *v. a.* (*mis* and *infer.*) To infer wrong (*Hooker*).

To MISINFO'RM. *v. a.* (*mis* and *inform.*) To deceive by false accounts (*Milton*).

MISINFORMA'TION. *s.* (from *misinform.*) False intelligence; false accounts (*South*).

To MISINTE'RPRET. *v. a.* (*mis* and *interpret.*) To explain to a wrong sense (*Ben Jonson*).

To MISJO'IN. *v. a.* (*mis* and *join.*) To join unfitly or improperly (*Dryden.*)

MISITRA, a town of European Turkey, in the Morea; defended by a castle, on a rock, which is said to be impregnable. It was the ancient Sparta. The Christians have several churches, one among them called Perileptos, said to be one of the most beautiful in the world. The Jews have three synagogues; and the Turks have a superb mosque and hospital. It is the see of a Greek archbishop, and the residence of a bey, an aga, and a waywode, and contains 12,000 inhabitants: forty miles S.S.W. Argos, forty E.N.E. Navarin, and sixty S. Corinth. Lon. 22. 30 E. Lat. 37. 6 N.

To MISJU'DGE. *v. n.* (*mis* and *judge.*) To form false opinions; to judge ill (*Pope*).

To MISLA'Y. *v. n.* (*mis* and *lay.*) To lay in a wrong place (*Dryden*).

MISLA'YER. *s.* (from *mislay.*) One that puts in the wrong place (*Bacon*).

To MI'SLE. *v. n.* (from *mist.*) To rain in imperceptible drops (*Derham*).

To MISLE'AD. *v. a.* (*mis* and *lead.*) To guide a wrong way; to betray to mischief or mistake (*Bacon*).

MISLE'ADER. *s.* (from *mislead.*) One that leads to ill (*Shakspeare*).

MI'SLEN. *s.* (corrupted from *miscellane.*) Mixed corn: as, wheat and rye (*Mortimer*).

MISLETOE, in botany. See Viscum.

To MISLI'KE. *v. a.* (*mis* and *like.*) To disapprove; to be not pleased with (*Herbert*).

Misli'ke. *s.* (from the verb). Disapprobation; dislike (*Fairfax*).

MISLI'KER. *s.* (from *mislike.*) One that disapproves (*Ascham*).

To MISLI'VE. *v. n.* (*mis* and *live.*) To live ill (*Spenser*).

To MISMA'NAGE. *v. a.* (*mis* and *manage.*) To manage ill (*Locke*).

MISMA'NAGEMENT. (*s. mis* and *ma*-

nagement.) Ill management; ill conduct (*Pope*).

To MISMA'TCH. *v. a.* (*mis* and *match.*) To match unsuitably (*Southern*).

To MISNA'ME. *v. a.* (*mis* and *name.*) To call by the wrong name (*Boyle*).

MISNOMER, in law, a misnaming or mistaking a person's name. The Christian name of a person should always be perfect; but the law is not so strict in regard to surnames, a small mistake in which will be dispensed with to make good a contract, and support the act of the party.

To MISOBSE'RVE. *v. a.* (*mis* and *observe.*) Not to observe accurately (*Locke*).

MISO'GAMIST. *s.* (μιςῶ and γάμος.) A marriage hater.

MISO'GYNY. *s.* (μισῶ and γυνή.) Hatred of women.

To MISO'RDER. *v. a.* (*mis* and *order.*) To conduct ill; to manage irregularly (*Shaks.*).

MISO'RDER. *s.* (from the verb.) Irregularity; disorderly proceedings (*Camden*).

MISO'RDERLY. *a.* (from *misorder.*) Irregularly; unlawful (*Ascham*).

To MISPE'ND. *v. a.* (*mis* and *spend.*) To spend ill; to waste; to consume to no purpose; to throw away (*Ben Jonson*).

MISPE'NDER. *s.* (from *mispend.*) One who spends ill or prodigally (*Norris*).

MISPERSUA'SION. *s.* (*mis* and *persuasion.*) Wrong notion; false opinion (*Decay of Piety*).

MISPICKEL, in mineralogy. See FERRUM and ARSENICUM.

To MISPLA'CE. *v. a.* (*mis* and *place.*) To put in a wrong place (*South*).

To MISPRI'SE. *v. a.* Obsolete. 1. To mistake (*Shakspeare*). 2. To slight; to scorn; to despise (*Shakspeare*).

MISPRI'SION. *s.* (from *misprise.*) 1. Scorn; contempt: not in use (*Shakspeare*). 2. Mistake; misconception: not in use (*Gla.*) 3. (In common law.) Neglect, negligence, or oversight. *Misprision* of treason, is the concealment of known treason. *Misprision* of felony, is the letting any person, committed for felony, to go before he be indicted (*Cowell*).

To MISPROPO'RTION. *v. a.* (*mis* and *proportion.*) To join without due proportion.

MISPRO'UD. *a.* (*mis* and *proud.*) Viciously proud: obsolete (*Shakspeare*).

To MISQUO'TE. *v. a.* (*mis* and *quote.*) To quote falsely (*Shakspeare*).

To MISRECI'TE. *v. a.* (*mis* and *recite.*) To recite not according to the truth (*Bramhall*).

To MISRE'CKON. *v. a.* (*mis* and *reckon.*) To reckon wrong; to compute wrong (*Swift*).

To MISRELA'TE. *v. a.* (*mis* and *relate.*) To relate inaccurately or falsely (*Boyle*).

MISRELA'TION. *s.* (from *misrelate.*) False or inaccurate narrative (*Bramhall*).

To MISREME'MBER. *v. a.* (*mis* and *remember.*) To mistake by trusting to memory (*Boyle*).

To MISREPO'RT. *v. a.* (*mis* and *report.*) To give a false account of (*Hooker*).

MISREPO'RT. *s.* False account; false and malicious representation (*South*).

To MISREPRESE'NT. *v. a.* (*mis* and *represent.*) To represent not as it is; to falsify to disadvantage (*Swift*).

MISREPRESENTA'TION. *s.* 1. The act of misrepresenting (*Swift*). 2. Account maliciously false (*Atterbury*).

MISRU'LE. *s.* (*mis* and *rule.*) Tumult; confusion; revel; unjust domination (*Thoms*).

MISS. *s.* (contracted from *mistress.*) 1. The term of honour to a young girl (*Swift*). 2. A strumpet; a concubine (*Dryden*).

To MISS. *v. a.* preter. *missed*; part. *missed* or *mist.* (*missen*, Dutch.) 1. Not to hit by the mind; to mistake (*Milton*). 2. Not to hit by manual aim (*Pope*). 3. To fail of obtaining (*Dryden*). 4. To discover something to be unexpectedly wanting (*Sidney*). 5. To be without (*Shakspeare*). 6. To omit (*Prior*). 7. To perceive want of (*South*).

To MISS. *v. n.* 1. To fly wide; not to hit (*Waller*). 2. Not to succeed (*Bacon*). 3. To fail; to mistake. 4. To be lost; to be wanting (*Milton*). 5. To miscarry; to fail (*Milton*). 6. To fail to obtain, learn, or find (*Atterbury*).

MISS. *s.* (from the verb.) 1. Loss; want (*Locke*). 2. Mistake; errour (*Ascham*). 3. Hurt; harm: obsolete (*Spenser*).

MI'SSAL. *s.* (*missale*, Lat. *missel*, Fr.) The mass book (*Stillingfleet*).

To MISSA'Y. *v. n.* (*mis* and *say.*) To say ill or wrong (*Hakewill*).

To MISSE'EM. *v. n.* (*mis* and *seem.*) 1. To make false appearance (*Spenser*). 2. To misbecome: obsolete both (*Spenser*).

MISSEL BIRD, a species of TURDUS.

To MISSE'RVE. *v. a.* (*mis* and *serve.*) To serve unfaithfully (*Arbuthnot*).

To MISSHA'PE. *v. a.* (*mis* and *shape.*) To shape ill; to form ill; to deform (*Bentley*).

MI'SSILE. *a.* (*missilis*, Latin.) Thrown by the hand; striking at distance (*Pope*).

MISSIO, among the Romans, was a full discharge given to a soldier after twenty years service, and differed from the *exauctoratio*, which was a discharge from duty after seventeen years service. Every soldier had a *right* to claim his missio at the end of twenty years.

MI'SSION. *s.* (*missio*, Latin.) 1. Commission; the state of being sent by supreme authority (*Milton. Atterbury*). 2. Persons sent on any account, usually to propagate religion (*Bacon*). 3. Dismission; discharge: not in use (*Bacon*). 4. Faction; party: not in use (*Shakspeare*).

MISSION, in theology, denotes a power or commission to preach the gospel. Jesus Christ gave his disciples their mission in these words, "Go and teach all nations, &c."

The Romanists reproach the Protestants, that their ministers have no mission; as not being authorised in the exercise of their ministry, either by an uninterrupted succession from the apostles, or by miracles, or by any extraordinary proof of a vocation.

Many among us deny any other mission necessary for the ministry than the talents necessary to discharge it.

Mission is also used for an establishment of people zealous for the glory of God, and the salvation of souls; who go and preach the gospel in remote countries and among infidels.

There are missions in the East, as well as in the West Indies. Among the Romanists, the religious orders of St. Dominic, St. Francis, St. Augustine, and the Jesuits, have missions in the Levant, America, &c.

The Jesuits have had missions in China, and all other parts of the globe, where they have been able to penetrate. The Mendicants abound in missions.

There have been also several Protestant missions for diffusing the light of Christianity through the benighted regions of Asia and America. Of this kind has been the Danish mission, planned by Frederic IV. in 1706. And the liberality of private benefactors in our own country has been also extended to the support of missionaries among the Indians in America, &c.

The first Protestant mission in India was sent out by the Protestant churches of Denmark and Germany, being planned by Frederic IV. as just mentioned. Their two first missionaries, Bartholomew Ziegenbalgh and Henry Plutscho, arrived in India in July 1706: and the Hindoo churches celebrated a jubilee in July 1806, in commemoration of that happy event. During the whole of the last century Providence favoured them with a succession of pious and learned men, educated at the German universities; among whom was the venerable Schwartz, called the apostle of the east; and others not much inferior to him; men whose names are scarcely known in this country, but who are as famous among the Hindoos as Wickliffe and Luther are among us. The ministry of these good men was blessed in many provinces in the south of India to the conversion of more than 18,000 Hindoos; and the bounds of their churches are extending unto this day. The language of the country is called the Tamul; and the first translation of the Bible, in that language, was made about 100 years ago. Like Wickliffe's Bible with us, it became the father of many versions, and, after a succession of improved editions, it is now considered by the Brahmins themselves (like Luther's Bible in German) as the classical standard of the Tamul tongue. The records of this mission are published in upwards of 30 quarto vols. and some interesting extracts from them have been published, during the last 15 months, in the Christian Observer.

The Dutch in the island of Ceylon, and other of their East India settlements, have had still more extensive success. In North America, the apostolic Elliott, in the last century, was the chief instrument of the evident and thorough conversion of many of the native Indians. The Church of England has long established a society for foreign missions. The Presbyterian society in Scotland for propagating Christian knowledge has lent its support to several useful missionaries among the American Indians. The Moravian brethren have, within these seventy years, sent missions to various heathen nations. The Wesleyan Methodists have, within these few years, attempted a mission to the Caribs, who are natives of the West India islands, and have laboured with success among the negro slaves in those islands. Of late years this missionary spirit has revived afresh, and hereby the hopes of Christians have been revived, that the Lord Jesus is about to extend his kingdom in the earth.

The most important society is denominated "The particular Baptist society for propagating the Gospel among the heathens." Its origin was from Mr. Carey, who printed a pamphlet with a view to encourage the sending forth missionaries. His heart appears to have been set upon the conversion of the heathen for several years, and his conversations, prayers, and sermons, were mostly accompanied with something relative to this subject. He possessed, at the same time, a great thirst for geographical knowledge, and a remarkable aptitude at learning languages, so that his most intimate friends were, for several years past, induced to think that he was formed for some such undertaking. His desire that a society might be established amongst his connexions for the propagation of the Gospel among the heathen, and that be might have a share in that important service, continued, and increased, till, at length, in the year 1791, being at a meeting of ministers at Clipstone in Northamptonshire, he proposed a question, "Whether it were not practicable, and our bounden duty, to attempt somewhat toward spreading the Gospel in the heathen world?" The chief thing then agreed upon was to desire Mr. Carey to draw up his thoughts on the subject and publish them. At the annual Baptist association at Nottingham, May 21, 1792, a resolution was made, "that a plan be prepared against the next meeting of ministers at Kettering, for forming a society among the Baptists for propagating the Gospel among the heathens." At the meeting at Kettering, October 2, 1792, a foundation for such a society was laid, and several resolutions agreed to. At a second meeting of the primary society at Northampton, October 31, 1792, Mr. Pearce of Birmingham gave information, that having mentioned the business to his friends, they had generously contributed seventy pounds to assist in the noble design. At a third meeting at Northampton, November 13, 1792, some farther resolutions were entered into, and an address of the society to their fellow Christians at large was agreed to be prepared, printed, and circulated. On January 10, 1793, a committee meeting was held at Kettering, when the committee being of opinion that a door was opened in the East Indies, Mr. Carey was asked, whether he was inclined to go, who answered in the affirmative. The object now was to calculate the expences, and obtain the means of defraying them. This was soon accomplished, for no sooner was the design made known than cheerful and liberal contributions came from different parts of the kingdom. The church at Leicester, though greatly affected by the loss of a faithful pastor, yet offered no objection to his going. "We have been praying (said one of them) for the spread of Christ's kingdom amongst the heathens; and now God requires us to make the first sacrifice to accomplish it." Before his departure a solemn day was spent in prayer at Leicester, March 20, 1793, when Mr. Fuller of Kettering gave a very suitable and affecting address on the occasion, which is published in the Baptist periodical accounts of their mission, No. I. On June 13, 1793, he set sail on board the Princessa Maria, a Danish East Indiaman, Captain Christmas. Mr. Carey, and Mr. Thomas, who accompanied him, with their families, kept up morning and evening worship in the ship, though surrounded with infidels and profane people; and an infidel who went with them, and is since returned, has said, "If ever there was a good man in this world, Carey was one." Pleasing accounts of his success have been often since received. He has been in defatigable in his labours, has translated nearly the whole Bible into the Bengalee tongue.

The whole number of persons baptized, from the commencement of the mission to the end of 1808, appears to be about 150, of whom a large proportion are native Indians. Among these, we perceive, with pleasure, no fewer than ten Brahmins, of whom, though several have gone back, yet two are now engaged in preaching the Gospel. Additions have been made to this list since the year 1808.

On the subject of translating the Scriptures into the oriental languages, a statement has been received from the missionaries, of which we will give the substance.

1. The Bengalee Bible is completed. A third edition of it is printing in folio, to be used in public worship.

2. In the Orissa, the New Testament is printed, and nearly the whole Book of Psalms. The edition consists of 1000 copies. A mission is about to be undertaken in Orissa.

3. In the Telinga, the New Testament is translated, and a beginning made in the Old.

4. In the Kernata, the progress is nearly the same as in the Telinga.

5. The translation and printing of the Guserattee had been suspended for the present.

6. In the Mahrattah, the four Gospels are nearly printed off. The whole of the New Testament is translated, and a part of the Old.

7. The printing of the New Testament in Hindoostanee had been suspended after half was completed, but they hoped soon to proceed with it.

8. In the Panjabee, or language of the Seiks, the translation of the New Testament is finished, and the printing begun.

9. In the Sungskrit, the whole of the New Testament is printed off, and as far as the middle of Exodus in the Old.

10. The translation of the Scriptures into the Burman language has been begun by the missionaries.

11. The Chinese translation is in a state of progress; the printing has proceeded as far as the middle of St. Matthew's Gospel.

THE FOLLOWING IS A GENERAL SUMMARY.

LANGUAGES.	PROBABLE EXTENT TO WHICH THEY ARE SPOKEN.	PRESENT PROGRESS.
Bengalee,	About Great Britain,	Bible printed.
Sungskrit,	Read all over India,	N.T. ditto.
Orissa,	About Ireland,	N.T. ditto.
Hindoostanee,	About France and Italy,	N.T. printing.
Mahratta,	About Great Britain,	N.T. ditto.
Guzeratic,		N.T. ditto.
Chinese,	Read all over China,	N.T. of these six last translating for the press.
Telinga,	About England,	
Carnatic,	The same,	
Siku or Seeks,		
Persian,	Persia, read in India,	
Burman,	Burmah, about 70 mill.	

The New Testament in the Malayala is also printing at Serampore for the use of the inhabitants of Travancore.

The following is a List of the Missionaries, now in the East Indies.

Dr. William Carey, sen.	At Serampore and Calcutta.
Mr. Joshua Marshman,	ditto ditto.
William Ward,	ditto ditto.
Joshua Rowe,	ditto ditto.
John Chamberlaine,	Cutwa, in Bengal.
Richard Mardon,	Goamalty, ditto.
William Moore,	Miniary, ditto.
James Chater,	Rangoon, in Burmah.
Felix Carey,	ditto.
William Robertson,	Boutan.
William Carey, jun.	Saddamahl, in Bengal.

Of these missionaries Carey and Marshman are learned as well as pious and diligent men: so that besides their occupations in the mission, which they discharge with great faithfulness and zeal, they employ themselves in making known to their countrymen, through the medium of translations, the most valuable portions of eastern literature. Marshman is now translating the works of Confucius; and has already sent over to England an interesting account of Chinese literature. The labours of these excellent men in fact establish a remarkable era, marked by the contemporaneous translation of the New Testament into twelve eastern languages. Men of no religion may scoff, and men of half learning may sneer; but posterity will class the names of Carey and Marshman with that of sir William Jones, and will be astonished that any literary journal should have tarnished its reputation by an unprincipled attack upon such men. See further, the Baptist periodical accounts, No. I to 20; and the Quarterly Review, No. 1 and 10.

The establishment of this Baptist society gave rise to another, of a yet more extensive nature, including various denominations of Christians. The first publication which stood in immediate connection with the rise of this society was an address to professors of the Gospel, published in the Evangelical Magazine, September 1794. This address gave occasion to various private conversations; at length, on November 4, 1794, the first concerted meeting with a view to this society took place. It was a small, but glowing and harmonious circle of ministers of various connections and denominations. In January, 1795, a printed address was sent to a considerable number of ministers in London and its neighbourhood, and a meeting was appointed on December 15, 1794, at the Castle and Falcon Inn, Aldersgate-street. At the time specified they met together, and began jointly to call on God in reference to the salvation of the heathens, mingling their applications with the reading of portions of Scripture, and afterwards consulting together on the best expedients for the formation of a regular society; it was unanimously determined, that all party names and inferior distinctions should, in the prosecution of this vast design, be absorbed in the great Christian name and cause. And these meetings, held regularly once a fortnight, with much sacred pleasure and unanimity were resorted to with a gradual increase of numbers, of zeal, hope, and delight. A committee of correspondence was opened with brethren in all parts of the country, and at length a general meeting was appointed in September 1795. A preparatory meeting was held on September 21, when the sketch of a plan prepared by the committee was read, which was approved as proper to be laid before the general meeting on the ensning day, and subscription books were opened. On Tuesday, the 22d, and the two following days, there were successively held, in various parts of the city, six solemn assemblies for worship. The animated solemnity, unity, and zeal of these assemblies, which were very great, the spirit with which they were enlivened to the last, and the solid effects of ever-flowing liberality, for the advancement of the work in view, encouraged them to hope the design was of God. On the 25th they proceeded to choose directors and secretaries, and unanimously resolved, that the first attempt of this society should be to send missionaries to Otaheite, or some other of the islands of the South Sea. Accordingly preparations were made and completed, and 30 men, 6 women, and 3 children, approved by the directors, embarked on board the ship Duff, Capt. Wilson, on August 10, 1796, and arrived at Otaheite March 5, 1797.

In addition to the above, we must mention, that the missionary ship Duff, (on a second voyage to Otaheite) as it was entering the harbour of Rio Janeiro on the coast of Spanish America, was captured by the Buonaparte, a French privateer, on the 19th of February, 1799. Not far from the spot where they were captured by the Buonaparte they were retaken by the convoy of the Brazil fleet to Lisbon, "when we were again (says the Rev. Mr. Howell in his Letter to Joseph Hardcastle, Esq. dated Lisbon, Sept. 26, 1799) pleasing ourselves with the prospect of entering the harbour of Rio Janeiro for the purpose of procuring some necessary supplies, and where we hoped to be able to fix the plan of our future movements. Every arrangement in view was, however, by this unexpected event, completely superseded; and it was now no longer a question where we should go, but where we must go. Such a peculiar providence indeed, you will readily judge, put an end to every debate on this subject, and finally determined our duty to return home *re infecta*." Thirty-six of the missionaries arrived at Falmouth on the morning of the 12th of October, in the Prince of Wales packet. See farther on the subject of this mission, Quarterly Rev. No. 3.

Besides the above mentioned Missionary Societies, others, having the same object in view, have lately been formed in Scotland, at Edinburgh, Glasgow, Aberdeen, Stirling, Kelso, Paisley, Greenock, Perth, Dundee, &c. Some of these have generously contributed to the society of Particular Baptists in England for propagating the Gospel, to be applied towards defraying the expence of printing a translation of the Bible into the Bengalee language, in which their missionaries in the East Indies have already made considerable progress. They have also sent kind benefactions to the Missionary Society of London, by which they have expressed, in the strongest terms, their willingness to co-operate in the grand undertaking.

We must not omit noticing the Moravian missions. The United Brethren (commonly called Moravians) have particularly distinguished themselves for many years, in endeavouring to send the Gospel of Christ among heathen nations. From the writings of Count Zinzendorf, and from the sentiments and practices of others among the United Brethren, at certain periods of their history, many have formed unfavourable opinions of the whole denomination, and very harsh accounts have been given of them in some publications of respectability. It may therefore be proper to observe, that the United Brethren do not take the writings of any man as their standard of doctrine; the Bible alone is their standard of truth; and they agree with the Augsburg confession, as being conformable to it, that they acknowledge errors among some of their society at former periods: in particular, that they disclaim many of the extravagancies which are contained in the writings ascribed to Count Zinzendorf; and that from their works of a more recent date they seem now to teach the leading doctrines of the Gospel in great purity, and with much scriptural simplicity.

The most flourishing missions at present are those in Greenland, Antigua, St. Kitt's, the Danish West India islands, and the Cape of Good Hope. A new awakening has appeared of late among the Arawacks and Free Negroes in South America, the Esquimaux of the coast of Labrador, and in Barbadoes. And the latest accounts give us the most pleasing hopes of success in those parts. The inhabitants of the earth amount to about seven hundred and thirty-one millions: four hundred and twenty millions of whom are still in pagan darkness: an hundred and thirty millions the followers of Mohammed; an hundred millions Catholics; forty millions Protestants, thirty millions of the Greek and Armenian churches; and, perhaps, seven millions of Jews. It must undoubtedly strike every considerate mind what a vast proportion of the sons of Adam there are who yet remain in the most deplorable state of heathen stupidity, without any means of knowing the true God, except what are afforded them by the works of nature, and utterly destitute of the gospel of Christ, or of any means of obtaining it. This lamentable picture is the most cogent argument that can be used against those who oppose missions; and this must furnish our apology for having devoted a few pages to the subject.

MI′SSIONARY. MI′SSIONER. *s.* (*missionaire*, French.) One sent to propagate religion (*Swift. Dryden*).

MISSISIPPI, a river of North America, which is said to rise about the 47th degree of north latitude, and between the 95th and 96th degrees of longitude west from Greenwich. It receives a great number of rivers in its course, and some of them very large: the direction is, with considerable winding, southerly to the Gulf of Mexico, where it empties itself betwen the 89th and 90th degrees of lougitude west from London, and the 29th and 30th of north latitude.

MI′SSIVE. *a.* (*missive*, French.) 1. Such as is sent (*Ayliffe*). 2. Used at distance (*Dryden*).

MI′SSIVE. *s.* (French.) 1. A letter sent (*Bacon*). 2. A messenger: both obsolete (*Shakspeare*).

MISSON (Francis Maximilian), whose pleadings before the Parliament of Paris in favour of the reformers bear genuine marks of eloquence and ability, retired into England after the revocation of the edict of Nantz, and became a strenuous assertor of the Protestant religion. In the year 1687 and 1683 he travelled to Italy as governor to an English nobleman: in consequence of which he published at the Hague A new Voyage to Italy, 3 vols. 12mo.; which has been translated into English with many additions. He published also, the Sacred Theatre at Cevennes, or an Account of Prophecies and Miracles performed in that Part of Languedoc. London, 1707. Observations and Remarks of a Traveller, 12mo. Hague. He died at London in 1721.

To MISSPE′AK. *v. a.* (*mis* and *speak.*) To speak wrong (*Donne*).

MISSOURI, a river of North America, whose source is unknown. It joins the Missisippi in lat. 39° E, but is a longer, broader, and deeper river, and is, in fact, the principal stream. It has been ascended by the French traders upwards of 1200 miles, and from its depth and breadth at that distance appeared to be navigable much higher.

MISSUS, in the Circensian games, were the matches in horse or chariot races. The usual number of *missus* or matches in one day was 24; though the emperor Domitian presented the people with 100. The last match was generally made at the expence of the people, who made a collection for the purpose; hence it was called *missus ærarius*, a subscription plate.

MIST. *s.* (mıꞅꞇ, Saxon.) 1. A low thin cloud; a small thin rain not perceived in drops. (See FOG.) 2 Any thing that dims or darkens (*Dryden*).

To MIST. *v. a.* (from the noun.) To cloud; to cover with a vapour or steam (*Shakspeare*).

MISTA′EN. pret. and part. pass. of *mistake* for *mistaken* (*Shakspeare*).

MISTA′KABLE. *a.* (from *mistake.*) Liable to be conceived wrong (*Brown*).

To MISTA′KE. *v. a.* (*mis* and *take.*) To conceive wrong; to take something for that which it is not (*Stillingfleet*).

To MISTA′KE. *v. n.* To err; not to judge right (*Raleigh*).

To be MISTA′KEN. To err (*Waller*).

MISTA′KE. *s.* (from the verb.) Misconception; errour (*Tillotson*).

MISTA′KINGLY. *ad.* (from *mistaking.*) Erroneously; falsely (*Boyle*).

To MISTA′TE. *v. a.* (*mis* and *state.*) To state wrong (*Sanderson*).

To MISTE′ACH. *v. a.* (*mis* and *teach.*) To teach wrong (*Sanderson*).

To MISTE′MPER. *v. a.* (*mis* and *temper.*) To temper ill; to disorder (*Shakspeare*).

MI′STER. *a.* (from *mestier*, trade, French.) What *mister*, what *kind of*: obsolete (*Spens.*).

To MISTE′RM. *v. a.* (*mis* and *term.*) To term erroneously (*Shakspeare*).

To MISTHI′NK. *v. a.* (*mis* and *think.*) To think ill; to think wrong (*Milton*).

To MISTI′ME. *v. a.* (*mis* and *time.*) Not to time right; not to adapt properly with regard to time.

MI′STINESS. *s.* (from *misty.*) Cloudiness; state of being overcast (*Bacon*).

MI′STION. *s.* (from *mistus*, Latin.) The state of being mingled (*Boyle*).

MISTLETO′E. *s.* (mẏꝫꞅleꞇan, Sax.) See VISCUM.

MI′STLIKE. *a.* (*mist* and *like.*) Resembling a mist (*Shakspeare*).

MI′STRESS. *s.* (*maitresse.* French.) 1. A woman who governs: correlative to *subject* or to *servant* (*Arbuthnot*). 2. A woman who has something in possession (*Sidney*). 3. A woman skilled in any thing (*Addison*). 4. A woman teacher (*Swift*). 5. A woman beloved and courted (*Clarendon*). 6. A term of contemptuous address (*Shakspeare*). 7. A whore; a concubine.

MISTRU′ST. *s.* (*mis* and *trust.*) Diffidence; suspicion; want of confidence (*Milton*).

To MISTRU′ST. *v. a.* To suspect; to doubt; to regard with diffidence (*Cowley*).

MISTRU′STFUL. *a.* (*mistrust* and *full.*) Diffident; doubting (*Waller*).

MISTRU′STFULLY. *ad.* With suspicion.

MISTRU′STFULNESS. *s.* (from *mistrustful.*) Diffidence; doubt (*Sidney*).

MISTRU′STLESS. *a.* (from *mistrust.*) Confident; unsuspecting (*Carew*).

MISTURA. (*mistura.*) In medicine, a mixture. It is mostly contracted into mist. e. g.—f. mist. which means, let it be made into a mixture.

MISTURA CAMPHORÆ. A very elegant preparation of camphire, for delicate stomachs and those who cannot bear it in substance as an antispasmodic and nervine. There is a great loss of camphire in making it as directed by the pharmacopœia. Water can only make up a certain quantity.

Mistura cretæ. A very useful and pleasant form of administering chalk as an astringent and antacid. It is particularly calculated for children, in whom it allays the many deranged actions of the primæ viæ, which are produced by acidities. The new Pharmacopœia of the London college contains six other forms.

Mistura moschi. A diaphoretic and antispasmodic musk julep. It is by far the best way of administering musk, when boluses cannot be swallowed.

MI'STY. *a.* (from *mist.*) 1. Clouded; overspread with mists (*Wotton*). 2. Obscure; dark; not plain.

To MISUNDERSTA'ND. *v. a.* (*mis* and *understand.*) To misconceive; to mistake (*Add.*).

MISUNDERSTA'NDING. *s.* 1. Difference; disagreement (*Swift*). 2. Errour; misconception (*Bacon*).

MISU'SAGE. *s.* (from *misuse.*) 1. Abuse; ill use. 2. Bad treatment.

To MISU'SE. *v. a.* (*mis* and *use.*) To treat or use improperly; to abuse (*South*).

Misu'se. *s.* (from the verb.) 1. Evil or cruel treatment (*Shakspeare*). 2. Wrong or erroneous use (*Locke*). 3. Misapplication; abuse (*Atterbury*).

To MISWE'EN. *v. n.* (*mis* and *ween.*) To misjudge; to distrust: obsolete (*Spenser*).

To MISWE'ND. *v. n.* (*mis* and ƿenꝺan, Saxon.) To go wrong: obsolete (*Fairfax*).

MISY. In mineralogy. See Chalcantha.

MITCHELA, in botany, a genus of the class tetrandria, order monogynia. Corols one-petalled, superior, two on each germ; stigmas four; berry bifid, four-seeded. One species only, M. repens, a North American plant with stem decumbent; leaves opposite, roundish, entire; flowers double, terminal.

MITCHELL (Joseph), a dramatic writer, was born in Scotland in 1684. He was patronized by sir Robert Walpole, but died poor, owing to his extravagance, in 1738. His works are, 1. The Fatal Extravagance, a tragedy; 2. The Highland Fair, a ballad opera, 8vo.; 3. Poems, 2 vols. 8vo.

MITCHELSTOWN, a post town of Ireland, in the county of Cork and province of Munster, 102 miles from Dublin. Here is a college for the support of 12 decayed gentlemen and 12 decayed gentlewomen, who have 40l. yearly, and handsome apartments, and a chaplain at 100l. a-year, with a house: divine service is daily performed in a neat chapel belonging to the college: the whole was founded by the late earl of Kingston. Here is also a most magnificent seat of Lord Kingsborough.—Fairs are held at this town 30th July and 12th of November.

MITE, a small piece of money mentioned Luke xii. 59. and xxi. 2. In the Greek it is κοδραντης, i. e. quadrans, or a quarter of the Roman denarius; so that the mite was worth about seven farthings or two-pence of our money.

Mite, in zoology. See Acarus.

Mite also denotes any thing proverbially small.

MITELLA. Bastard American sanicle. Inb otany,a genus of the class decandria, orde digynia. Calyx five-cleft; corol five-petalled, inserted into the calyx; the petals pinnatified; capsule one-celled, two-valved; the valves equal. Three species, one of Asia, and two of America, with annual herbaceous stalks, from five or six to eight or nine inches high, with small whitish flowers, the petals fringed at their edges.

MITHRADATES, a herdsman of Astyages, ordered to put young Cyrus to death. He refused, and educated him at home as his own son, &c.—*Herodot. Justin.*

MITHRAS, a god of Persia, supposed to be the sun. His worship was introduced at Rome, and the Romans raised him altars, on which was this inscription, *Deo Soli Mithræ*, or *Soli Deo invicto Mithræ.* He is generally represented as a young man, whose head is covered with a turban, after the manner of the Persia n

MITHRIDATE, Mithridatium, in pharmacy, an antidote, or composition, in form of an electary; serving either as a remedy or a preservative against poisons. Mithridate is one of the capital medicines in the apothecaries shops, being composed of a vast number of drugs; among which are opium, myrrh, agaric, saffron, ginger, cinnamon, spikenard, frankincense, castor, pepper, gentian, &c.

It is accounted a cordial, opiate, sudorific, and alexipharmic. Matthiolus says, it is more effectual against poison than Venice treacle, and much easier to be made.

It takes its name from its inventor Mithridates, king of Pontus, who is reported to have so fortified his body against poisons, with antidotes and preservatives, that when he had a mind to dispatch himself, he could not find any poison that would take effect.

Mithridate mustard. See Thlaspi campestre.

MITHRIDATEA, in botany, a genus of the class monandria, order digynia. Receptacle many-flowered, four-cleft, calyxless, corolless, seeds solitary, immersed in the fleshy receptacle. One species only, M. quadrifida, a Madagascar tree, with opposite branches; leaves ever-green, opposite, elliptic, entire, veined; flowers solitary, peduncled, four-cleft lateral; fruit fleshy, the size of an ordinary apple.

MITHRIDATES. This name was common to seven kings of Pontus: the most conspicuous and celebrated of them is the last, sirnamed Eupator, and the Great, who succeeded his father Mithridates VI. though only at the age of 11 years. The beginning of his reign was marked by cruelty and artifice. He murdered his own mother, who had been left by his father coheiress of the kingdom, and he fortified his constitution by drinking antidotes against the poison with which his enemies at court attempted to destroy him. Naturally ambitious and cruel, he spared no pains to acquire himself power and dominion. He murdered the two sons whom his sister Laodice had had by Ariarathes, king of Cappadocia, and placed one of his own children, only eight years old, on the vacant throne. The Romans became the arbiters in the appointment of the true successor, and having discovered dissimulation and fraud both on the side of Nicomedes, king of Bithynia, and Mithridates, they took away the kingdom of Cappadocia from Mithridates, and Paphlagonia from Nicomedes. This was the first ground of enmity beween Rome and the king of Pontus. (See *Mithridaticum bellum*.) Mithridates then meditated retaliation, and, the more effectually to destroy their power in Asia, he ordered all the Romans that were in his dominions to be massacred. This was done in one night, and no less than 150,000, according to Plutarch, or 80,000 Romans, as Appian mentions, were made, at one blow, the victims of his cruelty. This universal massacre called loud for revenge. Aquilius, and soon after Sylla, marched against Mithridates with a large army. The former was made prisoner, but Sylla obtained a victory over the king's generals, and another decisive engagement rendered him master of all Greece, Macedonia, Ionia, and Asia Minor, which had submitted to the victorious arms of the monarch of Pontus. Mithridates, weakened by repeated ill success by sea and land, then sued for peace, which he obtained, on condition of defraying the expences which the Romans had incurred by the war, and of remaining satisfied with the possessions which he had received from his ancestors. While these negociations of peace were carried on, Mithridates was not unmindful of his real interest. His poverty, and not his inclinations, obliged him to wish for peace. He, however, shortly after took the field with an army of 140,000 infantry, and 16,000 horse; and Lucullus, the consul, marched into Asia, and without delay blocked up the camp of Mithridates, who was then besieging Cyzicus. The Asiatic monarch escaped from him, and fled into the heart of his kingdom. The appointment of Glabrio to the command of the Roman forces instead of Lucullus was favourable to Mithridates, and he recovered the greatest part of his dominions. The sudden arrival of Pompey, however, soon put an end to his victories. A battle, in the night, was fought near the Euphrates, in which an universal overthrow ensued, and Mithridates, bold in his misfortunes, rushed through the thick ranks of the enemy, at the head of 800 horsemen, 500 of which perished in the attempt to follow him. He fled to Tigranes, but that monarch refused an asylum to his father-in-law, whom he had before supported with all the collected forces of his kingdom. Mithridates, however, found a safe retreat among the Scythians. His subjects, at last, refused to follow him any longer, and they revolted from him, and made his son Pharnaces king. The son showed himself ungrateful to his father. This broke the heart of Mithridates; he obliged his wife Monime to poison herself, and attempted to do the same himself; but the frequent antidotes he had taken in the early part of his life strengthened his constitution against the poison, and, when this was unavailing, he attempted to stab himself. The blow was not mortal, and a Gaul, who was then present, at his own request, gave him the fatal stroke, about 63 years B. C. in the 72d year of his age. Such were the misfortunes, abilities, and miserable end of a man, who supported himself so long against the power of Rome. Mithridates has been commended for his eminent virtues, and censured for his vices. He was the greatest monarch that ever sat on a throne, according to the opinion of Cicero. His skill in physic is well known, and even now there is a celebrated antidote which bears his name, and is called Mithridate. The conduct of Mithridates to his wife has given birth to a fine tragedy, that of Monimia, in the earl of Carysfort's dramatic and narrative poems, recently published. This name is common also to other kings in Armenia, Pergamus, Pontus and Parthia.

MITHRIDATICUM BELLUM, begun 89 years B. C. was one of the longest and most celebrated wars ever carried on by the Romans against a foreign power. The ambition of Mithridates VII. king of Pontus, from whom it receives its name, may be called the cause and origin of it. His views upon the kingdom of Cappadocia, of which he was stripped by the Romans, first engaged him to take up arms against the republic. (Vid. *Mithridates*.) According to Justin, Orosius, Florus, and Eutropius, it lasted for 40 years; but the opinion of others, who fix its duration to 30 years, is far more credible; and upon proper calculation, there elapsed no more than 26 years from the time that Mithridates first entered the field against the Romans till the time of his death.

MI'TIGANT. *a.* (*mitigans*, Lat.) Lenient; lenitive.

To MI'TIGATE. *v. a.* (*mitigo*, Latin.) 1. To soften; to make less rigorous (*Hooker*). 2. To alleviate; to make mild (*Hooker*). 3. To mollify; to make less severe (*Milton*). 4. To cool; to moderate (*Addison*.)

MITIGA'TION. *s.* (*mitigatio*, Lat.) Abatement of any thing penal, harsh, or painful (*Bacon*).

MITRA, a cap or cover worn by the Roman ladies.

MITRAL VALVES. *Valvulæ mitrales.* In anatomy, the valves of the left ventricle of the heart are so called from their resemblance to a mitre.

MI'TRE, in helminthology. See Voluta.

MITRE, Mitra, from μιτρα, which signifies the same; a pontifical ornament, worn on the head by bishops, and certain abbots, on solemn occasions.

The mitre is a round cap, pointed, and cleft at top, with two pendants hanging down on the shoulders, and fringed at both ends. The bishop's is only surrounded with a fillet of gold, set with precious stones; the archbishop's issues out of a ducal coronet. These are never used otherwise than on their coats of arms. Abbots wear the mitre turned in profile, and bear the crosier inwards, to shew that they have no spiritual jurisdiction without their own cloisters.

The pope has also granted to some canons of cathedrals the privilege of wearing the mitre. The counts of Lyons are also said to have assisted at church in mitres.

In Germany several great families bear the mitre for their crest; to shew that they are advocates, or feudatories, of ancient abbeys, or officers of bishops, &c.

The pope has four mitres, which are more or less rich, according to the solemnity of the feast-days they are to be worn on. The mitre was originally the women's head-dress, as the hat was that of the men. This appears from Remulus in Virgil, who reproaches the Trojans, that they were dressed like women, and wore mitres. *Et tunicæ manicas et habent redimicula mitræ.*

The cardinals anciently wore mitres, before the hat, which was first granted them by the council of Lyons, in 1243. Authors make no mention of the mitre as an episcopal ornament before the year 1000.

Mitre, in architecture, is the workmen's term for an angle that is just 45 degrees, or half a right one.

If the angle be a quarter of a right angle, they call it a half-mitre.

Mitre is used by the writers of the Irish history for a sort of base money, which was very common there about the year 1270, and for 30 years before, and as many after. There were beside the mitre several other pieces called according to the figures impressed upon them, rosaries, lionades, eagles, and by the like names. They were imported from France and other countries, and were so much below the proper currency of the kingdom, that they were not worth so much as a halfpenny each. They were at length decried in the year 1300, and good coins struck in their place.

MITRED. *a.* (*mitré*, French, from *mitre.*) Adorned with a mitre (*Prior*).

MITTAU, the capital of the duchy of Courland. It is strongly fortified; but was taken by the Swedes in 1701, and by the Muscovites in 1706. Lon. 23. 51 E. Lat. 56. 44 N.

MI'TTENT. *a.* (*mittens*, Latin.) Sending forth; emitting (*Wiseman*).

MI'TTENS. *s.* (*mitains*, French.) 1. Coarse gloves for the winter (*Peacham*). 2. Gloves that cover the arms without covering the fingers.

MITTIMUS, as generally used, hath two significations. 1. It signifies a writ for removing or transferring of records from one court to another. 2. It signifies a precept, or command in writing, under the hand and seal of a justice of the peace, directed to the gaoler or keeper of some prison, for the receiving and safe keeping of an offender charged with any crime until he be delivered by due course of law.

MITYLENE, or Mytelene (anc. geog.), a celebrated, powerful, and affluent city, capital of the island of Lesbos. It receives its name from Mitylene, the daughter of Macareus, a king of the country. It is greatly commended by the ancients for the stateliness of its buildings and the fruitfulness of its soil, but more particularly for the great men it produced. Pittacus, Alcæus, Sappho, Terpander, Theophanes, Hellanicus, &c. were all natives of Mitylene. It was long a seat of learning; and with Rhodes and Athens it had the honour of having educated many of the great men of Rome and Greece. In the Peloponnesian war, the Mityleneans suffered greatly for their revolt from the power of Athens; and in the Mithridatic wars they had the boldness to resist the Romans, and disdain the treaties which had been made betwen Mithridates and Sylla.

To MIX. *v. a.* (*misceo*, Latin.) 1. To unite to something else (*Hosea*). 2. To unite various ingredients into one mass (*Esdras*). 3. To form of different substances (*Bacon*). 4. To join; to mingle (*Shakspeare*).

To Mix. *v. n.* To be united into one mass by mutual intromission of parts (*Milton*).

MI'XEN. *s.* (mixen, Saxon.) A dunghill; a laystall.

MIXO-LYDIAN. (Greek.) The name of one of the modes in the ancient music, called also hyper-dorian. The mixo-lydian mode was the most acute of the seven to which Ptolemy reduced the Greek music.

MI'XTION. *s.* (*mixtion*, French.) Mixture; confusion of one thing with another (*Digby*).

MI'XTLY. *ad.* (from *mix.*) With coalition of different parts into one.

MI'XTURE. *s.* (*mixtura*, Latin.) 1. The act of mixing; the state of being mixed (*Arbuthnot*). 2. A mass formed by mingled ingredients. 3. That which is added and mixed (*Addison*).

MIXTURE, a compound or assemblage of several different bodies in the same mass. Simple mixture consists only in the simple apposition of parts of different bodies to each other. Thus, when powders of different kinds are rubbed together the mixture is only simple, and each of the powders retains its particular character. In like manner, when oil and water are mixed together, though the parts of both are confounded, so that the liquor may appear to be homogeneous, we cannot say that there is any more than a simple apposition of the parts, as the oil and water may very easily be again separated from each other. But the case is very different when bodies are chemically mixed; for then one or both bodies assume new properties, and can by no means be discovered in their proper form without a particular chemical process adapted to this purpose.

Hence chemical mixture is attended with many phenomena which are never observed in simple mixtures; such as heat, effervescence, &c.

MIZEN. See Misen.

MI'ZZY. *s.* A bog; a quagmire (*Ains.*).

MNASIUM, in botany, a genus of the class hexandria, order monogynia. Spathe two-valved, many flowered: calyx three-parted; corol one-petalled, three-toothed, with a very short tube; anthers terminated by a leaflet; stigmas three, spirally twisted. One species only, an aquatic plant of Guiana, with involucred, panicled, yellow flowers.

MNEMO'NICKS. *s.* (μνημονικη.) The art of memory.

MNEMOSYNE (fab. hist.), a daughter of Cœlus and Terra. She married Jupiter, by whom she had the nine Muses. The word Mnemosyne signifies "memory;" and therefore the poets have rightly called Memory the mother of the Muses, because it is to that mental endowment that mankind are indebted for their progress in science.

MNIARUM, in botany, a genus of the class monandria, order digynia. Calyx four-parted, superior; corolless; seed one. One species only; a New Zealand herb, with subsessile flowers terminating in pairs.

MNIUM. Marsh-moss. In botany, a genus of the cryptogamia musci class and order. Natural order of mosses. Generic character: capsule with a lid; calyptre smooth; bristle from a terminating tubercle: male flowers headed, or discoid. Twenty species are enumerated, among which M. hygrometricum is the most remarkable. If the fruit stalk be moistened at the bottom, the head makes three or four turns; and if the head be moistened it turns the contrary way. By some authors this is ranged with the Bryums; and Hedwig makes it a Koelreuteria.

MO *a.* (ma, Saxon.) Making greater number: more: obsolete. (*Spenser*).

MO. *ad.* Further; longer: obsolete. (*Shaks.*)

MOAB (anc. geog.), a country of Arabia Petræa; so called from Moab the son of Lot, to whose posterity this country was allotted by divine appointment, Deut. xi. 9. It was originally occupied by the Emim, a race of giants extirpated by the Moabites, *ibid.* Moab anciently lay to the south of Ammon, before Sihon the Amorite stripped both nations of a part of their territory, afterwards occupied by the Israelites, Numb. xxi.; and then Moab was bounded by the river Arnon to the north, the Lacus Asphaltites to the west, the brook Zared to the south, and the mountains Abarim to the east.

To MOAN. *v. a.* (from mænan, Saxon, to grieve.) To lament; to deplore.

To Moan. *v. n.* To grieve, to make lamentation (*Thomson*).

Moan. *s.* Lamentation; audible sorrow (*Shakspeare*).

MOAT. *s.* (*motte*, French.) A canal of water round a house or castle for defence (*Sid.*).

To Moat. *v. a.* (*motter*, French.) To surround with canals by way of defence (*Dry.*).

Moat, or Ditch, in fortification, a deep trench dug round the rampart of a fortified place to prevent surprises.

The brink of the moat, next the rampart, is called the scarp; and the opposite one, the counterscarp. A dry moat round a large place, with a strong garrison, is preferable to one full of water; because the passage may be disputed inch by inch, and the besiegers, when lodged in it, are continually exposed to the bombs, granades, and other fire-works, which are thrown in incessantly from the rampart into their works. In the middle of dry moats there is sometimes another small one called cunette, which is generally dug so deep till they find water to fill it. The deepest and broadest moats are accounted the best, but a deep one is preferable to a broad one: the ordinary breadth is about twenty fathoms, and the depth about sixteen.

To drain a moat that is full of water, they dig a trench deeper than the level of the water to let it run off, and then throw hurdles upon the mud and slime, covering them with earth or bundles of rushes, to make a sure and firm passage.

MOB. *s.* (from *moble.*) A kind of female undress for the head.

Mob. *s.* (contracted from *mobile*, Latin.) The crowd; a tumultuous rout (*Dryden*).

To Mob. *v. a.* (from the noun.) To harass, or overbear by tumult.

MO'BBISH. *a.* (from *mob.*) Mean; done after the manner of the mob.

MO'BBY. *s.* An American drink made of potatoes.

MO'BILE. *s.* (*mobile*, French.) The populace; the rout; the mob (*L'Estrange*).

MOBILE, moveable, any thing susceptible of motion, or that is disposed to be moved either by itself or by some other prior mobile, or mover.

Mobile (Primum), in the ancient astronomy, was a ninth heaven, or sphere, imagined above those of the planets and fixed stars.

This was supposed to be the first mover, and to carry all the lower spheres round along with it; by its rapidity communicating to them a motion whereby they revolved in twenty-four hours. But the diurnal revolution of the planets is now accounted for, without the assistance of any such *primum mobile.*

MOBILES, in the ancient music, was an appellation given to the two intermediate chords of a tetrachord; because their variations produced the different genera and species of music. They were called by the Greeks κινητοι, or κινουμενοι.

MOBI'LITY. *s.* (*mobilité*, Fr. *mobilitas*, Latin.) 1. The power of being moved (*Locke*). 2. Nimbleness; activity (*Blackmore*). 3. (In cant language.) The populace (*Dryden*). 4. Fickleness; inconstancy (*Ainsworth*).

To MO'BEL. *v. a.* To dress grossly or inelegantly (*Shakspeare*).

MOCHLICA, a term given by some authors to drastic purges.

MOCHA-STONE, in mineralogy. See CHALCEDONIUS. The term is a corruption from the German *moch-stein*, or moss-stone.

MOCHA, or MOKA, a considerable town of Arabia Felix, surrounded by walls. It carries on a great trade, especially in coffee; and the inhabitants are computed at 10,000, without including the poor Armenians, or the Jews, who inhabit the suburbs. The women, except a small number of the common sort, never appear in the streets in the day time, but visit each other in the evening. When they meet any men in the way, they stand up close against the wall to let them pass. Their dress is much like other women of the East, and over all they wear a large veil of painted calico, so thin that they can see through it without being seen. They have also little buskins of Morocco leather. The English at present engrosss almost exclusively the trade of this place: the Portuguese having long since ceased to send any ships hither, and the Dutch rarely sending any. Mocha is seated in a sandy country, near the straits of Babelmandel, 240 miles S.S.W. of Sanaa, and 560 S.S.E. of Mecca. Lon. 44. 25 E. Lat. 14. 0 N.

To MOCK. *v. a.* (*mocquer*, French.) 1. To deride; to laugh at; to ridicule (*Job*). 2. To deride by imitation; to mimic in contempt *Shakspeare*). 3. To defeat; to elude (*Shaks*). 4. To fool; to tantalize; to play on contemptuously (*Milton*).

To MOCK. *v. n.* To make contemptuous sport (*Job*).

MOCK. *s.* (from the verb.) 1. Ridicule; act of contempt; sneer; gibe; flirt (*Tillotson*). 2. Imitation; mimickry (*Crashaw*).

MOCK *a.* False; counterfeit; not real (*Dryden*).

MOCK-ORANGE, in botany. See PHILADELPHUS.

MOCK-PRIVET. See PHILLYNEAS.

MOCKABLE. *a.* Exposed to derision (*Shakspeare*).

MO'CKEL. *a* (the same with *mickle.*) Much, many (*Spenser*).

MO'CKER. *s.* (from *mock.*) 1. One who mocks; a scorner; a scoffer (*Shakspeare*). 2. A deceiver; and elusory impostor.

MO'CKERY. *s.* (*mocquerie*, French.) 1. Derision; scorn; sportive insult (*Watts*). 2. Ridicule; contemptuous merriment (*Hook*). 3. Sport; subject of laughter (*Shakspeare*). 4. Vanity of attempt; vain effort (*Shaks.*). 5. Imitation; counterfeit appearance; vain show (*Shakspeare*).

MOCKING-BIRD, in ornithology. See ORIOLUS and TURDUS.

MO'CKINGLY. *ad.* (from *mockery*). In contempt; petulantly; with insult.

MO'CKING-STOCK. *s.* (*mocking* and *stock*). A butt for merriment.

MO'DAL. *a* (*modale*, French.) Relating to the form or mode, not the essence (*Glan.*).

MODA'LITY. *s.* (from *modal.*) Accidental difference; modal accident (*Holder*).

MODBURY, a town in Devonshire, with a market on Thursday. It is seated in a bottom, between two hills, 36 miles S.S.W. of Exeter, and 208 W.S.W. of London. Lon. 3. 54 W. Lat. 50. 23 N.

MODE. *s.* (*mode*, French; *modus*, Latin.) 1. External variety; accidental discrimination; accident (*Watts*). 2. Gradation; degree (*Pope*). 3. Manner; method; form; fashion (*Taylor*). 4. State; quality (*Shakspeare*). 5. Fashion; custom (*Addison*).

MODE, in grammar. See GRAMMAR.

MODE, or MOOD, (*modus*), in philosophy, a manner of being, or a quality or attribute of a substance, or subject, which we conceive as necessarily depending on the subject, and incapable of subsisting without it.

Mr. Locke defines modes to be those ideas (he should have said things) which do not imply any supposition of subsisting by themselves, but are considered as mere dependences, and affections of substances.

Our ideas of things may be reduced to two kinds: the one of things, which we conceive separately, and by themselves, called substances; and the other of things which we conceive as existing in others, in such manner as that we cannot allow them existing without them, and these we call modes or accidents.

It is the characteristic, then, of a true mode to have such a relation to some subject, as not to be clearly and distinctly conceivable without conceiving the subject, whereof it is a mode, at the same time: when, on the other hand, the conception of the subject does not at all infer or require that of the mode.

Thus what gives us to know, that thought is not a mode of extended substance, or matter, is, that extension, and the other properties of matter, may be divided from thought, without ceasing to conceive thought all the while.

We always consider things as clothed with certain modes, except we reflect on them in the abstract, or general: and it is the variety of modes, and the relations, that occasions the great variety of denominations of the same thing. They are the various modes of matter, e. g. that make all the diversity of bodies, or corporeal beings, in nature.

There are various divisions and kinds of modes: as, 1. Essential or accidental. An essential mode, or attribute, is that which belongs to the very nature or essence of the subject wherein it is: and the subject can never have the same nature without it, as roundness in a bowl, solidity in matter, thinking in a spirit, &c. and this is primary, when it is the first or chief thing that constitutes any being in its particular essence or nature, and makes it to be that which it is, and distinguishes it from all other beings, as roundness in a bowl; or secondary, which is any other attribute of a thing, that is not of primary consideration, called a property; as volubility in a bowl. An accidental mode, or accident, is such a mode as is not necessary to the being of a thing; for the subject may be without it, and yet remain of the same nature which it had before; or it is that mode, which may be separated from its subject; as, blackness or whiteness in a bowl, learning in a man, &c.

2. Modes are absolute and relative. An absolute mode is that which belongs to its subject, without respect to any other beings whatsoever. A relative mode is derived from the regard which one being has to others: thus, roundness and

smoothness are the absolute modes of a bowl; but greatness and smallness are relative. See Relation.

3. Modes are intrinsical or extrinsical. The former are conceived to be in the subject or substance; as when we say a globe is round, &c. The latter mode is a manner of being which some substances attain by reason of something that is external or foreign to the subject, and is called external denomination; as, this globe lies within two yards of the wall, &c.

4. Modes are also inherent or adherent, i. e. proper or improper. Adherent modes arise from the joining of some accidental substance to the chief subject, which yet may be separated from it; as when a bowl is wet, &c. Inherent modes have a sort of in-being in the substance itself; as, the bowl is swift or round, &c.

5. Action and passion, using the terms in a philosophical sense, are modes which belong to substances; as, when a smith with a hammer strikes a piece of iron, the smith and hammer are agents or subjects of action, and the iron is the patient or subject of passion.

6. Modes may be divided into natural, civil, moral, and supernatural, all which pertain to the apostle Paul, who was a little man, a Roman by the privilege of his birth, a man of virtue or honesty, and an inspired apostle.

7. Modes belong either to body, or to spirit, or to both. Modes of body belong only to matter, or to corporeal beings; such are figure, rest, motion, &c. These are primary, when they belong to bodies, considered in themselves, whether there were any man to take notice of them or no, as shape, size, &c. or secondary, which are such ideas as we ascribe to bodies on account of the various impressions that are made on the senses of men by them, called secondary qualities; such are all colours, sounds, tastes, smells, and all tactile qualities. (See Quality.) Modes of spirit belong only to minds, such are knowledge, will, &c. Modes belonging to body and spirit are called mixed or human modes, because they are found in human nature, such are sensation, imagination, passion, &c. in which there is a concurrence of the operation of animal and intellectual nature.

8. There are also modes of other modes, which, though they subsist in and by the substance, as the original subject of them, are properly and directly attributed to some mode of that substance; thus, swiftness and slowness are modes of motion, which is itself the mode of a body.

Mode, in music, the particular order of the concinnous degrees of an octave, the fundamental note whereof may be called the key, as it signifies that principal note which regulates the rest. The proper difference, therefore, between a mode and a key is this, that an octave with all natural and concinnous degrees is called a mode, with respect to the constitution or manner of dividing it; and with respect to its place in the scale it is called a key.

There is this difference between the mode and the tone, that the latter only determines the principal sound, and indicates the place which is most proper to be occupied by that system which ought to constitute the bass of the air; whereas the former regulates the thirds, and modifies the whole scale agreeably to its fundamental sounds.

Sir Francis Haskins Eyles Styles, in an elaborate essay on the modes of the ancients, Phil. Trans. vol. li. 695, has undertaken to prove that the two doctrines on this subject, which he distinguishes by the epithets of harmonic and musical, and which have been advanced by different writers, are in reality the same. According to one of these, viz. the harmonic, the difference between one mode and another consisted in the tension or pitch of the system; and, according to the other, or musical, this difference consisted in the manner of dividing an octave, or in the different species of the diapason: but both these definitions of a musical mode perfectly coincide. This author observes, that, according to the harmonic doctrine, the numbers of the modes had been augmented to fifteen; but Ptolemy, who appears to have favoured the musical, reduces them to seven: of these seven, according to the direction furnished by Bacchius, p. 12. ed Meibom. it appears, that the Mixolydian was the most acute; the Lydian graver by a semitone; the Phrygian graver than the Lydian by a tone; the Dorian graver than the Phrygian by a tone; the Hypolydian graver than the Dorian by a semitone; the Hypophrygian graver than the Hypolydian by a tone; and the Hypodorian graver than the Hypophrygian by a tone. Now as the Guidonian scale, in use among the moderns, answers to the system of the ancients in its natural situation, which was in the Dorian mode, and our A la mi re, consequently, answers to the pitch of the Dorian mese: we have a plain direction for finding the absolute pitch of the meses for all the seven in our modern notes, and they will be found to stand thus:

Mixolydian mese in	*d*
Lydian in	*c sharp*
Phrygian in	*b*
Dorian in	*a*
Hypolydian in	*g sharp*
Hypophrygian in	*f sharp*
Hypodorian in	*e*

But to understand this doctrine as delivered by the ancients, it will be necessary also to examine how the meses of the seven modes were stationed upon the lyre. The lyre, after its last enlargements, consisted of fifteen strings, which took in the compass a dis-diapason, or double octave. These strings were called by the same names as the fifteen sounds of the system; and, when tuned for the Dorian mode, corresponded exactly with them. In this mode the mese of the system was placed in the mese of the lyre; but in every one of the rest, it was applied to a different string, and every sound of the system transposed accordingly. Hence arose the distinction between a sound in power and a sound in position; for when the system was transposed from the Dorian to any other mode, e. g. to the Phrygian, the mese of the lyre, though still mese in position, acquired in this case the power of the lichanos meson; and the paramese of the lyre, though still paramese in position, acquired the power of the mese. In these transpositions one or more of the strings always required new tunings, to preserve the relations of the system; but, notwithstanding this alteration of their pitch, they retained their old names, when spoken of, in respect to their positions only; for the name implied not any particular pitch of the string, but only its place upon the lyre, in the numerical order, reckoning the proslambanomenos for the first. The places of the mese for the seven modes upon the lyre are settled by Ptolemy as follow:

			string.
Mixolydian	Mese in	Paranetediezeugmenon	11
Lydian		Tritediezeugmenon	10
Phrygian		Paramese	9
Dorian		Mese	8
Hypolydian		Lichanos meson	7
Hypophrygian		Parhypate meson	6
Hypodorian		Hypate meson	5

On the other hand, the musical doctrine taught, that the difference between one mode and another consisted in the manner of dividing an octave, or in the different species of diapason. These were, as we have already observed, seven in number; and had the denominations of Mixolydian, Lydian, Phrygian, Dorian, Hypolydian, Hypophrygian, and Hypodorian. See DIAPASON.

These species, as they stand in the system, are with respect to acuteness and gravity in the inverted order of the seven modes as settled by the harmonic doctrine. According to the Guidonian scale, and preserving the natural notes, they will stand in the manner represented under diapason.

The order of the intervals of which each species is composed, proceeding in each from grave to acute, will be as follows:

Mixolydian. Semitone, tone, tone, semitone, tone, tone, tone.

Lydian. Tone, tone, semitone, tone, tone, tone, semitone.

Phrygian. Tone, semitone, tone, tone, tone, semitone, tone.

Dorian. Semitone, tone, tone, tone, semitone, tone, tone.

Hypolydian. Tone, tone, tone, semitone, tone, tone, semitone.

Hypophrygian. Tone, tone, semitone, tone, tone, semitone, tone.

Hypodorian. Tone, semitone, tone, tone, semitone, tone, tone.

The ancients had another method of explaining the species of diapason by the position of the diazeuctic tone, or interval from mese to paramese. In the Mixolydian species, the diazeuctic tone was the first interval, reckoning from acute to grave; in the Lydian it was the second; in the Phrygian the third; in the Dorian the fourth; in the Hypolydian the fifth; in the Hypophrygian the sixth; and in the Hypodorian the last.

The ancient modes, besides their general division into authentic and plagal, had also their respective names from the several Greek provinces where they are supposed to have been invented. Originally indeed there were but three, viz. Doric, Lydian, and Phrygian; which were particularly called tones, because at a tone's distance from one another. The rest were added afterwards, and were some of them named from the relations they bore to the former, particularly the Hypo-doric, as being below the Doric. See the preceding part of this article.

The Doric mode was a mixture of gravity and mirth, invented by Thamyras of Thrace.

The Phrygian mode was adapted to the kindling of rage; and was invented by Marsyas the Phrygian.

The Lydian mode was proper for amorous or funeral songs; and was invented, according to Pliny, by Amphion.

The Mixolydian was invented by Sappho. The Æolic, Ionic, and Hypo-dorian by Philoxenus. And the Hypolydian by Polymnestes. See DORIC, &c.

Besides these modes of tune, old authors have also introduced modes of time, or measures of notes. These at first were distinguished into greater and less, and each of these again into perfect and imperfect. But afterwards they reduced all into our four modes, which included the whole business of time. These modes are now disused.

Our modes are not, like those of the ancients, characterised by any sentiment which they tend to excite, but result from our system of harmony alone. The sounds essential to the mode are in number three, and form together one perfect chord. 1. The tonic or key, which is the fundamental note both of the tone and of the mode. (See TONE and TONIC.) 2. The dominant, which is a fifth from the tonic. (See DOMINANT.) 3. The mediant, which properly constitutes the mode, and which is a third from the same tonic. As this third may be of two kinds, there are of consequence two different modes. When the mediant forms a greater third with the tonic, the mode is major; when the third is lesser, it is minor.

The major mode is immediately generated by the resonance of sounding bodies, which exhibit the third major of the fundamental sound: but the minor mode is not the product of nature; it is only found by analogy and inversion. This is equally true upon the system of Sig. Tartini, as upon that of M. Rameau.

When the mode is once determined, every note in the scale assumes a name expressive of its relation to the fundamental sound, and peculiar to the place which it occupies in that particular mode. We subjoin the names of all the notes significant of their relative values and places in each particular mode, taking the octave of *ut* as an example of the major mode, and of *la* as an example of the minor.

Major,	*ut*	*re*	*mi*	*fa*	*sol*	*la*	*si*	*ut*,
Minor,	*la*	*si*	*ut*	*re*	*mi*	*fa*	*sol*	*la*:
	Tonic.	Second note.	Mediant.	Fourth note, or Sub-dominant.	Dominant.	Sixth note, or Sub-dominant.	Seventh note.	Octave.

It is necessary to remark, that when the seventh note is only a semitone distant from the highest in the octave, that is to say, when it forms a third major with the dominant, as *si* natural in the major mode, or *sol* sharp in the minor, that seventh sound is then called a sensible note, because it discovers the tonic and renders the tone appreciable.

Nor does each gradation only assume that name which is suitable to it; but the nature of each interval is determined according to its relation to the mode. The rules established for this are as follow:

1. The second note must form a second major above the tonic, the fourth note and the dominant should form a fourth and fifth exactly true; and this equally in both modes.

2. In the major mode, the mediant or third, the sixth and the seventh from the tonic, should always be major; for by this the mode is characterised. For the same reason these three intervals ought always to be minor in the minor mode: nevertheless, as it is necessary that the sensible note should likewise there be perceived, which can-

not be effectuated without a false relation whilst the sixth note still remains minor; this occasions exceptions, of which in the course of the air or harmony care must be taken. But it is always necessary that the cleff, with its transpositions, should preserve all the intervals, as determined with relation to the tonic, according to the species of the mode.

As all the natural chords in the octave of *ut* give, with relation to that tonic, all the intervals prescribed for the major mode, and as the case is the same with the octave of *la* for the minor mode, the preceding example, which is only given that we might have an opportunity of naming the notes, may likewise serve as a formula for the rule of the intervals in each mode.

This rule is not, as one might imagine, established upon principles that are merely arbitrary; it has its source in the generation of harmony: at least in a certain degree. If you give a perfect major chord to the tonic, to the dominant, and the sub-dominant, you will have all the sounds of the diatonic scale for the major mode: to obtain that of the minor, leaving still its third major to the dominant, give a third minor to the two other chords. Such is the analogy of the mode.

As this mixture of major and minor chords introduces into the minor mode a false relation between the sixth and the sensible note, to avoid this false relation they sometimes give the third major to the fourth note in ascent, or the third minor to the dominant in descending, chiefly by inverting the chords; but these in this case are licences.

There are properly no more than two modes, as we have seen: but there are twelve different sounds in the octave, which may be made fundamental sounds, and of consequence form as many keys or tones; and as each of these tones is susceptible of the major or minor mode, music may be composed in twenty-four modes or manners. Nay, in the manner of writing music, there are even thirty-four passable modes: but in practice ten are excluded; which when thoroughly examined are nothing else but a repetition of the other ten, under relations much more difficult, in which all the chords must change their names, and where it must cost any one some trouble to know what he is about. Such is the major mode upon a note raised above its natural pitch by a semitone, and the minor mode upon a note depressed by a semitone. Thus instead of composing upon *sol* sharp with a third major, it is much more eligible to operate upon *la* flat, which will give you an opportunity to employ the same tones; and instead of composing upon *re* flat with a third minor, you will find it more convenient to choose *ut* sharp for the same reason; viz. on one hand to avoid a *fa* with a double sharp, which would be equivalent to a *sol* natural; and on the other hand a *si* with a double flat, which would become a *la* natural.

The composer does not always continue in the same mode, nor in the same key, in which he has begun an air; but, whether to alter the expression or introduce variety, modes and keys are frequently changed, according to the analogy of harmony; yet always returning to those which have been first heard: this is called modulation.

From thence arises a new division of modes into such as are principal and such as are relative: the principal is that in which the piece begins and ends; the relative modes are such as the composer interweaves with the principal in the flow of the harmony. See MODULATION.

Others have proposed a third species, which they call a mixed mode, because it participates the modulation of both the others, or rather because it is composed of them; a mixture which they did not reckon an inconveniency, but rather an advantage, as it increases the variety, and gives the composer a greater latitude both in air and harmony. The mixed mode, however, is liable to serious objections; on which account we shall say no more respecting it in this place.

MO'DEL. *s.* (*modele*, Fr. *modulus*, Latin.) 1. A representation in little of something made or done (*Addison*). 2. A copy to be imitated (*Hooker*). 3. A mould; any thing which shows or gives the shape of that which it encloses (*Shakspeare*). 4. Standard; that by which any thing is measured (*South*).

To MODEL. *v. a.* (*modeler*, French.) To plan; to shape; to mould; to form; to delineate. (*Addison*).

MODEL, in a general sense, an original pattern, proposed for any one to copy or imitate. This word is particularly used in building for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings it is much the surest way to make a model in relievo, and not to trust to a bare design or draught. There are also models for the building of ships, &c. and for extraordinary staircases, &c.

They also use models in painting and sculpture; whence, in the academies, they give the term model to a naked man or woman, disposed in several postures, to afford an opportunity to the scholars to design in various views and attitudes.

Models in imitation of any natural or artificial substance, are most usually made by means of moulds composed of plaster of Paris. For the purpose of making these moulds this kind of plaster is much more fit than any other substance, on account of the power it has of absorbing water, and soon condensing into an hard substance, even after it has been rendered so thin as to be of the consistence of cream. This happens in a shorter or longer time, as the plaster is of a better or worse quality; and its good or bad properties depend very much upon its age, to which, therefore, particular regard ought to be had. It is sold in the shops at very different prices; the finest being made use of for casts, and the middling sort for moulds. It may be very easily coloured by means of almost any kind of powder excepting what contains an alkaline salt; for this would chemically decompose the substance of it, and render it unfit for use, the gypsum or plaster being a sulphat of lime, which would be composed by the alkali precipitating the lime. A very considerable quantity of chalk would also render it soft and useless, but lime hardens it to a great degree. The addition of common size will likewise render it much harder than if mere water is made use of. In making either moulds or models, however, we must be careful not to make the mixture too thick at first; for if this is done, and more water added to thin it, the composition must always prove brittle, and of a bad quality.

The particular manner of making models depends on the form of the subject to be taken. The process is easy where the parts are elevated only in a slight degree, or where they form only a right or obtuse angle with the principal surface from which they project; but where the parts project in smaller angles, or form curves inclined towards the principal surface, the work is more difficult. This observation, however, holds good only with regard to hard and inflexible bodies; for such as are soft may often be freed from the mould, even though they have the shape last mentioned. But though this is the case with the soft original substance, it is not so with the inflexible model when once it is cast.

The moulds are to be made of various degrees of thickness, according to the size of the model to be cast; and may be from half an inch to an inch, or, if very large, an inch and a half. Where a number of models are to be taken from one mould, it will likewise be necessary to have it of a stronger contexture than where only a few are required, for very obvious reasons.

It is much more easy to make a mould for any soft substance than a rigid one, as in any of the viscera of the animal body: for the fluidity of the mixture makes it easily accommodate itself to the projecting parts of the substance; and as it is necessary to inflate these substances, they may be very readily extracted again, by letting out the air which distended them.

When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself is slippery, as is the case with the internal parts of the human body, this need not be done: when necessary, it may be laid over with linseed oil by means of a painter's brush. The original is then to be laid on a smooth table, previously greased, or covered with a cloth, to prevent the plaster sticking to it; then surround the original with a frame or ridge of glazier's putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. A sufficient quantity of plaster is then to be poured as uniformly as possible over the whole substance, until it is every where covered to such a thickness as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained its hardness: when the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry, let it be well seasoned.

Having formed and seasoned the moulds, they must next be prepared for the casts by greasing the inside of them with a mixture of olive oil and lard in equal parts, and then filled with fine fluid plaster, and the plane of the mould formed by its resting on the surface of the table, covered to a sufficient thickness with coarse plaster, to form a strong basis or support for the cast, where this support is requisite, as is particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardness it will receive: after which the mould must be removed: but this is attended with some difficulty when the shape of the subject is unfavourable; and in some cases the mould must be separated by means of a small mallet and chisel. If by these instruments any parts of the model should be broken off, they may be cemented by making the two surfaces to be applied to each other quite wet; then interposing betwixt them a little liquid plaster; and lastly, the joint smoothed, after being thoroughly dry. Any small holes that may be made in the mould can be filled up with liquid plaster, after the sides of them have been thoroughly wetted and smoothed over with the edge of a knife.

In many cases it is altogether impracticable to prepare a mould of one piece for a whole subject; and therefore it must be considered how this can be done in such a manner as to divide the mould into the fewest pieces. This may be effected by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows as would not admit a separation of the mould. Where any internal pieces are required, they are first to be made; and then the outer pieces, after the former have become hard.

Besides the models which are taken from inanimate bodies, it has been frequently attempted to take the exact resemblance of people while living, by using their face as the original of a model whence to take a mould; and the operation, however disagreeable, has been submitted to by persons of the highest ranks in life. A considerable difficulty occurs in this, however, from the person's being apt to shrink and distort his features when the liquid is poured upon him; neither is he altogether without danger of suffocation, unless the operator well understands his business.

To avoid the former inconvenience, it will be proper to mix the plaster with warm instead of cold water, by which means the person will be under no temptation to shrink; and to prevent any danger of a fatal accident, the following method is to be practised. Having laid he person horizontally on his back, the head must be first raised by means of a pillow to the exact position in which it is naturally carried when the body is erect; then the parts to be represented must be very thinly covered over with fine oil of almonds, by means of a painter's brush: the face is then to be first covered with fine fluid plaster, beginning at the upper part of the forehead, and spreading it over the eyes, which are to be kept close, that the plaster may not come in contact with the globe; yet not closed so strongly as to cause any unnatural wrinkles. Cover then the nose and ears, plugging first up the meatus auditorii with cotton, and the nostrils with a small quantity of tow rolled up, of a proper size to exclude the plaster. During the time that the nose is thus stopped the person is to breathe through the mouth: in this state the fluid plaster is to be brought down low enough to cover the upper lip, observing to leave the rolls of tow projecting out of the plaster. When the operation is thus far carried on, the plaster must be suffered to harden; after which the tow may be withdrawn, and the nostrils left free and open for breathing. The mouth is then to be closed in its natural position, and the plaster brought down to the extremity of the chin. Begin then to cover that part of the breast which is to be represented, and spread the plaster to the outsides of the arms and upwards, in such a manner as to meet and join that which is previously laid on the face: when the whole of the mass has acquired its due hardness, it is to be cautiously lifted, without breaking or giving pain to the person. After the mould is constructed, it must be seasoned in the manner already directed; and when the mould is cast, it is to be separated from the model by means of a small mallet and chisel. The eyes, which are necessarily shewn closed, are to be carved, so that the eye-lids may be represented in an elevated posture; the nostrils hollowed out, and the back part of the head, from which, on account of the hair, no mould can be taken, must be finished according to the skill of the artist. The edges of the model are then to be neatly smoothed off, and the bust fixed on its pedestal. See also Cast.

MO'DELLER. *s.* (from *model.*) Planner; schemer; contriver (*Spectator*).

MODENA, an ancient city of Italy, capital of the Modenese, with a bishop's see. The cathedral, several of the churches, and some of the monasteries are handsome structures; and the ducal palace is richly furnished, and contains fine paintings. The citadel has been often taken, particularly by the king of Sardinia, in 1742. The inhabitants are said to be 40,000; and they make here the best masks for masquerades in all Italy. It is seated between the rivers Secchia and Panaro, 22 miles W. by N. of Bologna, 34 S. by E. of Mantua, and 60 N.N.W. of Florence. Lon. 11. 0 E. Lat. 44. 34 N.

Modena, or Modenese, a duchy of Italy, 50 miles long and 40 broad; bounded on the W. by that of Parma, on the N. by the duchies of Mantua and Mirandola, on the E. by the Bolognese and Ferrarese, and on the S. by Tuscany and the republic of Lucca. The soil is very fertile in corn, wine, oil, and fruits of different kinds. It also feeds a great number of cattle.

MO'DERATE. *a.* (*moderatus*, Latin.) 1. Temperate; not excessive (*Ecclus.*) 2. Not hot of temper (*Swift*). 3. Not luxurious; not expensive (*Shakspeare*). 4. Not extreme in opinion; not sanguine in a tenet (*Smalridge*). 5. Placed between extremes; holding the mean (*Hooker*). 6. Of the middle rate (*Dryden*).

To Mo'derate. *v. a.* (*moderor*, Latin.) 1. To regulate; to restrain; to still; to pacify; to quiet; to repress (*Spenser*). 2. To make temperate; to qualify (*Blackman*).

MO'DERATELY. *ad.* (from *moderate.*) 1. Temperately; mildly. 2. In a middle degree (*Waller*).

MO'DERATENESS. *s.* (from *moderate.*) State of being moderate; temperateness.

MODERA'TION. *s.* (*moderatio*, Latin.) 1. Forbearance of extremity; the contrary temper to party violence; state of keeping a due mean between extremes (*Atterbury*). 2. Calmness of mind; equanimity (*Milton*). 3. Frugality in expence (*Ainsworth*).

MODERA'TOR. *s.* (*moderator*, Latin.) 1. The person or thing that calms or restrains (*Walton*). 2. One who presides in a disputation, to restrain the parties from indecency, and confine them to the question (*Bacon*).

MO'DERN. *a.* (*moderne*, French.) 1. Late; recent; not ancient; not antique (*Bacon. Prior*). 2. In *Shakspeare*, vulgar; mean; common.

MO'DERNS. *s.* Those who have lived lately, opposed to the ancients (*Boyle*).

To MO'DERNISE. *v. a.* To adapt ancient compositions to modern persons or things.

MO'DERNISM. *s.* Deviation from the ancient and classical manner (*Swift*).

MO'DERNNESS. *s.* (from *modern.*) Novelty.

MO'DEST. *a.* (*modeste*, French.) 1. Not arrogant; not presumptuous (*Young*). 2. Not impudent; not forward (*Dryden*). 3. Not loose; not unchaste (*Shakspeare*). 4. Not excessive; not extreme (*Addison*).

MO'DESTLY. *ad.* (from *modest.*) 1. Not arrogantly; not presumptuously (*Swift*). 2. Not impudently; not forwardly; with respect (*Shakspeare*). 3. Not loosely; not lewdly; with decency. 4. Not excessively; with moderation.

MO'DESTY. *s.* (*modestie*, Fr. *modestas*, Lat.) 1 Not arrogance; not presumptuousness. 2. Not impudence; not forwardness. 3. Moderation; decency (*Shakspeare*). 4. Chastity; purity of manners (*Dryden*).

Modesty, in ethics, is sometimes used to denote humility; and sometimes to express chastity, or purity of sentiments and manners. Modesty, in this last sense, and as particularly applied to women, is defined by the authors of the Encyclopédie Methodique, as a natural, chary, and honest shame; a secret fear; a feeling on account of what may be accompanied with disgrace. Women who possess only the remains of a suspicious modesty, make but feeble efforts to resist: those who have obliterated every trace of modesty from their countenance, soon extinguish it completely in the soul, and throw aside for ever the veil of decency. She, on the contrary, who truly possesses modesty, passes over in silence attempts against her honour, and forbears speaking of those from whom she has received an outrage, when in doing so she must reveal actions and expressions that might give alarm to virtue.

The idea of modesty is not a chimera, a popular prejudice, or an illusion arising from laws and education. Nature, which speaks the same language to all men, has, with the unanimous consent of nations, annexed contempt to female incontinence. To resist and to attack are laws of her appointment: and while she bestows desires on both parties, they are in the one accompanied with boldness, in the other with shame. To individuals she has allotted long spaces of time for the purposes of self-preservation, and but moments for the propagation of their species. What arms more gentle than modesty could she have put into the hands of that sex which she designed to make resistance!

If it were the custom for both sexes to make and receive advances indiscriminately, vain importunity would not be prevented: the fire of passion would never be stirred up, but languish in tedious liberty; the most amiable of all feelings would scarcely warm the human breast; its object would with difficulty be attained. That obstacle, which seems to remove this object to a distance, in fact brings it nearer. The veil of shame only makes the desires more attractive. Modesty kindles that flame which it endeavours to suppress: its fears, its evasions, its cautions, its timid avowals, its pleasing and affecting finesses, speak more plainly what it wishes to conceal than passion can do without it: it is modesty, in short, which enhances the value of a favour, and mitigates the pain of a refusal.

MO'DESTY-PIECE. *s.* A narrow lace which runs along the upper part of the stays before, being part of the tucker (*Addison*).

MODICA, a town of Sicily, in Val-di-Noto, on a river of the same name, 25 miles S.W. of Syracuse. Lon. 15. 9 E Lat. 36. 48 N.

MO'DICUM. *s.* (Latin.) Small portion; pittance (*Dryden*).

MO'DIFIABLE. *a.* (from *modify.*) That may be diversified by accidental differences (*Locke*).

MO'DIFICABLE. *a.* (from *modify.*) Diversifiable by various modes.

MODIFICA'TION. *s.* (*modification*, Fr.) The act of modifying any thing, or giving it new accidental differences of external qualities or mode (*Newton*).

To MO'DIFY. *v. a.* (*modifier*, French.) 1. To change the external qualities or accidents of any thing; to shape (*Newton*). 2. To soften; to moderate (*Dryden*).

To MO'DIFY. *v. n.* To extenuate (*L'Estr.*).

MO'DILLON. *s.* (French.) Modillons, in architecture, are little brackets which are often set under the corinthian and composite orders, and serve to support the projecture of the larmier or drip. See ARCHITECTURE.

MODIOLUS. (*modiolus*, dim. of *modius*, a measure). In anatomy, the nucleus, as it were, of the cochlea of the ear is so termed. It ascends from the basis of the cochlea to the apex.

MO'DISH. *a.* (from *mode.*) Fashionable; formed according to the reigning custom (*Addison*).

MO'DISHLY. *ad.* Fashionably (*Locke*).

MO'DISHNESS. *s.* (from *modish.*) Affectation of the fashion.

MODON, a strong town of the Morea, with a safe harbour, and a bishop's see. It is seated on a promontory, projecting into the sea of Sapienza, 15 miles E. of Coron, and 95 S.W. of Napoli-di-Romania. Lon. 21. 35 E. Lat. 36. 56 N.

MODREVIUS (Andreas Frichius), secretary to Sigismund Augustus king of Poland, acquired considerable reputation by his learning and works. He broke off from the Romish church, favoured the Lutherans and Antitrinitarians, and took great pains in order to unite all Christian societies under the same communion. Grotius has placed him in the class of the reconcilers of the different schemes of religion. His principal work is entitled, *De republica emendanda.*

To MO'DULATE. *v. a.* (*modulor*, Lat.) To form sound to a certain key, or to certain notes (*Grew*).

MODULA'TION. *s.* (from *modulate.*) 1. The act of forming any thing to certain proportion (*Woodward*). 2. Sound modulated; harmony (*Thomson*).

MODULATION, in music, the art of conducting harmony, in composition, or extemporary performance, through those keys and modes which have a due relation to the fundamental, or original key. Though every piece, as is well known, has its principal or governing key, yet, for the sake of contrast and relief, it is not only allowable but necessary to pass from key to key, and from mode to mode; to assume different sharps or flats, and lead the ear through those transitions of tone and harmony which interest the feelings and delight the ear. But though in grand compositions there is no quality of greater importance than that of a masterly modulation, it is not easy to lay down rules for its accomplishment. Sometimes a gradual and almost insensible evolution of harmony is requisite to the composer's object; at other times a bold and sudden change can alone produce the necessary effect.

MO'DULATOR. *s.* (from *modulate.*) He who forms sounds to a certain key; a tuner (*Derham*).

MO'DULE. *s.* (*modulus*, Latin.) An empty representation; a model (*Shakspeare*).

MO'DULE, in architecture, a certain measure, or bigness, taken at pleasure, for regulating the proportions of columns, and the symmetry or disposition of the whole building. Architects generally choose the semidiameter of the bottom of the column for their module, and this they subdivide into parts or minutes.

MO'DULUS OF A LOGARITHM. See LOGARITHMS.

MO'DUS. *s.* (Latin.) Something paid as a compensation for tithes on the supposition of being a moderate equivalent (*Swift*).

MODZIR, a town of Lithuania, capital of a district of the same name. It is seated on the river Prypec, in a fertile country, 85 miles S.E. of Sluczk. Lon. 29. 10 E. Lat. 52. 5 N.

MOE. *a.* (ma, Saxon. See Mo.) More; a greater number (*Hooker*).

MOEBIUS, (Godfrey), professor of physic at Iena, was born at Lauch in Thuringia in 1611. He became first physician to Frederic William elector of Brandenburg, to Augustus duke of Saxony, and to William duke of Saxe-Weimar. He wrote several medical works, which are esteemed; and died at Halle, in Saxony, in 1664.

MOENIUS (Caius), a celebrated Roman consul, conqueror of the ancient Latins, 338 B.C. He was the first who hung up the prows, &c. of the galleys he had taken at the naval engagement of Actium, upon the place where the tribunes harangued the people; from whence it was called the *rostra.*

MOEHRINGIA. Mossy chickweed. In botany, a genus of the class octandria, order digynia. Calyx four-leaved; petals four; capsule one-celled, four-valved. One species only, an Alpine annual herb with white axillary flowers, erect, on slender one-flowered peduncles.

MŒRIS, a steward of the shepherd Menalcas, in Virgil's Ecl. 9. 2. A king of Egypt, the last of the 300 kings from Menes to Sesostris, and reigned 63 years. 3. A celebrated lake in Egypt, supposed to have been dug by the king of the same name. It is about 220 miles in circumference, and intended as a reservoir for the waters during the inundation of the Nile. There were two pyramids in it, 600 feet high, half of which lay under the water, and the other appeared on the surface.

MŒSIA, or Mysia, (anc. geog.) a country of Europe, extending from the confluence of the Savus and the Danube to the shores of the Euxine. It was divided into Upper and Lower Mœsia. Lower Mœsia was on the borders of the Euxine, and comprehended that tract of country which received the name of Pontus from its vicinity to the sea. Upper Mœsia lay beyond the other, in the inland country.

MOESKIRCH, a town of Suabia, belonging to the princes of Furstenburg, 18 miles N. of Constance, and 52 S. of Stutgard. Lon. 9. 11 E. Lat. 47. 56 N.

MOFFAT, a village of Scotland, in the shire of Annandale, 50 miles south-west of Edinburgh; famous for its sulphureous well, which has been in just estimation for above 150 years as a remedy in all cutaneous and scrophulous complaints; and for its chalybeate spring, perhaps the strongest in Britain, which was discovered about 50 years ago, and is of a very bracing quality. The place is chiefly supported by the company who resort thither for the benefit of its waters and air; but it has also a manufacture of coarse woollen stuffs. It is a well-built clean village; and contains many good and even elegant lodgings, a tolerable assembly-room, a bowling-green and walks, and one of the best inns between London and Edinburgh.

Moffat hills, the highest mountains in the S. of Scotland. They occupy the N. part of Annandale; and from these descend in different directions the Tweed, Clyde, and Annan, whose sources are but little distant from each other.

Moffat water, a cold sulphureous water, of a very simple composition. It is exhibited in cutaneous eruptions of every kind, scrophula, ill-conditioned and irritable sores, and in bilious and calculous complaints.

MOGADOR, an island and castle of Africa, in the kingdom of Morocco, near Cape Ozem. There are mines of gold and silver in one of the mountains. Lon. 9. 55 W. Lat. 31. 38 N.

MOGULS (Country of the), or Western Chinese Tartary, is bounded on the N. by Siberia, on the E. by Eastern Tartary, on the S. by the great Wall and Leao-tong, and on the W. by Independent Tartary. The Mogul Tartars have neither towns, villages, nor houses; they are wandering hordes, and live under tents, which they remove from one place to another, according as the temperature of the different seasons or the wants of their flocks require: they pass the summer on the banks of their rivers, and the winter at the foot of some mountain, or hill, which shelters them from the cutting north wind. They are naturally clownish, and dirty in their dress, as well as in their tents, where they live amid the dung of their flocks, which when dried they use for fuel instead of wood. Enemies to labour, they choose rather to be satisfied with the food with which their flocks supply them than take the trouble of cultivating the earth: it even appears that they neglect agriculture from pride. During the summer they live only on milk, which they obtain from their flocks, using without distinction that of the cow, mare, ewe, goat, and camel. Their ordinary drink is warm water, in which a little coarse tea has been infused; with this they mix cream, milk, or butter, according to their circumstances. They have also a method of making a kind of spirituous liquor of sour milk, especially of that of the mare. The Moguls are free, open, and sincere. They pride themselves chiefly on their dexterity in handling the bow and arrow, mounting on horseback, and hunting wild beasts. Polygamy is permitted among them; but they generally have only one wife. They burn the bodies of their dead, and carry the ashes to eminences, where they inter them, and cover the grave with a heap of stones, over which they plant a great number of small standards. They are unacquainted with the use of money, and trade only by barter. Although the Moguls might appropriate to themselves the spoils of a great number of animals, the skins which they use for clothing are generally those of their sheep. They wear the wool inmost, and the skin on the outside. The religion of the Mogul Tartars is confined to the worship of Fo. They have the most superstitious veneration for their lamas, who are clownish, ignorant, and licentious priests, to whom they attribute the power of calling down hail or rain; to these lamas they give the most valuable of their effects in return for prayers, which they go about reciting from tent to tent. These people are very devout, and continually wear hanging at their necks a kind of chaplet, over which they say their prayers. All the Moguls are governed by khans, or particular princes, independent of each other; but all subject to the emperor of China, whom they consider as the grand khan of the Tartars. When the Mantchews subdued China, they conferred on the most powerful of the Mogul princes the title of vang, peilé, peizé, and cong, which answer to our titles of king, duke, count, and marquis; each of them had a revenue assigned him, but far inferior to the appoinments of the Mantchew lords at Pekin: the emperor settled the limits of their respective territories, and appointed them laws, according to which they are at present governed. All the Mogul nations under the Chinese government may be divided into four principal tribes, which are the Moguls, properly so called, the Kalkas, the Ortous, and the Tartars of Kokonor.

MO'HAIR. *s.* (*mohere*, French.) Thread or stuff made of camels or other hair (*Pope*).

Mohair, in commerce, the hair of a kind of goat frequent about Angria in Turkey; the inhabitants of which city are all employed in the manufacture of camblets made of this hair. Some give the name mohair to the camblets or stuffs made of this hair: of these there are two kinds; the one smooth and plain, the other watered like tabbies: the difference between the two consists only in this, that the latter is calendered, the other not. There are also mohairs both plain and watered, whose woof is of wool, cotton, or thread.

Mohair-shell, in conchology, a name given to a peculiar species of voluta, which seems of a closely and finely reticulated texture, and resembles on the surface a piece of mohair, or a very close silk-worm's web.

MOHATZ, a town of Lower Hungary, in the county of Baraniwar. Here Louis, the last king of Hungary, in 1526, was defeated by the Turks under Soliman II. with the loss of 22,000 men, and after the battle suffocated by the fall of his horse in a muddy brook. In 1687, another battle was fought here between the Christians commanded by prince Charles of Lorrain, and the Turks, who were defeated with the loss of 10,000 men, their cannon and baggage. It is seated at the confluence of the Danube and Corasse, 17 miles N.W. of Esseck. Lon. 19. 56 E. Lat. 45. 46 N.

MOHAWK RIVER, a river of the state of New York, which rises to the north of Fort Stanwix, passes by that fort and Skenectady, and empties itself by two mouths into Hudson's River, eight miles above Albany. About two miles above its junction with that river it has a cataract, where the stream, 100 yards wide, falls perpendicularly about seventy feet.

MOHAWKS, a once powerful tribe of Indians in North America, living on the Mohawk River. Only one family are left of them in the state of New York, the rest having, in 1776, emigrated, with sir John Johnson, into Canada.

MOHELIA, or Mohila, one of the Comora Islands, between the island of Madagascar and the continent of Africa. Ships touch here in their passage to the East Indies. Lat. 11. 55 S. Lon. 45. 0 E.

MOHILOF, or Mohilow, a strong town of Lithuania, in Poland. The Swedes obtained a victory over the Russians near this place in 1707. Lat. 54. 10 N. Lon. 30. 0 E.

MOHURRUM, the annual commemoration of the death of the Imaum Hossein, observed among the Hindoos. This Hossein is reputed the second son of Ali by Fatima, the daughter of Mahommed. He was killed by the caliph Yezzeed of the house of Omar, at Kerbalaie in Erack Arabia, the ancient Mesopotamia. Those Musselmans who pretend to be the followers of Ali represent during the ten days of this festival all the traditional circumstances connected with the death of Hossein.

MOHRUNGEN, a town of Prussia, in the province of Oberland, situate on a lake of the same name, which almost surrounds it. Here is an old castle, formerly a convent, belonging to the knights of the Teutonic order, in consequence of whose wars the town has frequently suffered. It is 56 miles S.S.W. of Konigsberg, and 56 S.E. of Dantzic.

MO'IDERED. *a.* Crazed; mudded (*Ainsworth.*)

MO'IDORE. *s.* A Portugal coin, rated at one pound seven shillings.

MO'IETY. *s.* (*moitié*, French, from *moien*, the middle.) Half; one of two equal parts (*Clar.*).

To MOIL. *v. a.* (*mouiller*, French.) 1. To daub with dirt (*Knolles*). 2. To weary (*Chapman*).

To Moil. *v. n.* (*mouiller*, French.) 1. To labour in the mire (*Bacon*). 2. To toil; to drudge (*L'Estrange*).

MOINE (Stephen la), a learned French divine of the protestant persuasion, was born at Caen in 1624. He was professor of divinity at Leyden, and died in 1689. He wrote several esteemed theological treatises.

Moine (Peter le), a French poet, born at Chaumon in Bassigny in 1602. He was a jesuit, and wrote an epic poem, entitled, Saint Louis, ou la Couronne reconquisé sur les Infidelles. He died in 1672.

Moine (Francis le), a French painter, born at Paris in 1688. He painted the apotheosis of Hercules in the saloon at Versailles, for which the king made him his first painter, and gave him a large pension. He stabbed himself in a fit of lunacy in 1737.

MOIRA, (sometimes written *Moyra*), a town of Ireland, situated in the county of Down and province of Ulster, 69 miles from Dublin; noted for its linen manufacture, and a monthly market for vending the same. It gives title of earl to the family of Rawdon. Lord Moira has here a very beautiful seat; and here is a handsome church, a charity school, and two dissenting meeting-houses.

MOISSAC, an ancient town of France, in the department of Lot. It has a great trade in corn and flour, and is seated on the Tarn, near the Garonne, 13 miles N.W. of Montauban. Lon. 1. 17 E. Lat. 44. 6 N.

MOIST. *a.* (*moiste*, French.) 1. Wet, not dry; wet, not liquid; wet in a small degree (*Pope*). 2. Juicy; succulent (*Ainsworth*).

To Moist. *To* Moisten. *v. a.* (from *moist.*) To make damp; to make wet to a small degree; to damp (*Shakspeare*).

MO'ISTENER. *s.* (from *moisten.*) The person or thing that moistens.

MO'ISTNESS. *s.* (from *moist.*) Dampness; wetness in a small degree (*Addison*).

MO'ISTURE. *s.* (*moiteur*, French, from moist.) 1. State of being moist; moderate wetness (*Sidney*). 2. Small quantity of liquid (*Addison*).

MOIVRE (Abraham de), was born at Vitri

in Champagne, A.D. 1667. His father was a surgeon. At the revocation of the edict of Nantes he determined to fly into England rather than abandon the religion of his fathers. Before he left France he had begun the study of mathematics; and having perfected himself in that science in London, he was obliged, by the meanness of his circumstances, to teach it. Newton's Principia, which accidentally fell into his hands, showed him how little progress he had made in a science of which he thought himself master. From this and Newton's other work he acquired a knowledge of the geometry of infinites with as great facility as he had learned the elementary geometry; and in a short time he was fit to be ranked with the most celebrated mathematicians. His success in these studies procured him a seat in the Royal Society of London and in the Academy of Sciences at Paris. His merit was so well understood in the former, that he was thought capable of deciding in the famous dispute between Leibnitz and Newton concerning the differential calculus. He published a Treatise on Chances in 1738, and another on Annuities in 1752; both extremely accurate and valuable. The Philosophical Transactions contain many interesting memoirs of his composition.—Some of them treat of the method of fluxions; others are on the lunula of Hippocrates; others on physical astronomy, in which he resolved many important problems; and others, in short, on the analysis of the games of chance, in which he followed a different course from that of Montmort. Towards the close of his life he lost his sight and hearing; and the demand for sleep became so great that he required twenty hours of it in a day. He died at London, 1754, aged 87. His knowledge was not confined to mathematics; but he retained to the last a taste for polite literature. He was intimately acquainted with the best authors of antiquity; and he was frequently consulted about difficult passages in their works. Rabelais and Moliere were his favourite French authors; he had them by heart; and he one day observed to one of his acquaintance, "that he would rather have been Moliere than Newton." He recited whole scenes of the Misanthrope with that delicacy and force with which he remembered to have heard them recited at Paris 70 years before by Moliere's own company. He judged severely of mankind; and could never conceal his disgust at the conversation of a fool, nor his aversion to cunning and dissimulation. He was free from the affectation of science; and no one could know him to be a mathematician but from the accuracy of his thoughts. His conversation was general and instructive. Whatever he said was well digested and clearly expressed. His style possessed more strength and solidity than ornament and animation; but he was always correct, and he bestowed as much pains on his sentences as on his calculations. He could never endure any bold assertions or indecent witticisms against religion. "I show you that I am a Christian (said he one day to a person who thought to pay him a compliment by observing that mathematicians were attached to no religion), by forgiving the speech you have now made." The practice of giving vails to servants was not laid aside in his time; and, on this account, when a nobleman asked him why he did not dine oftener with him? "You must excuse me, my lord (replied he), I cannot afford it."

MOKES OF A NET. The meshes (*Ains.*).

MO'KY. *a.* Dark; murky (*Ainsworth*).

MOLA (Pietro Francesco), an eminent painter, was born, according to most authors, at Lugano, a city belonging to the Switzers, in the year 1609. Others affirm that the place of his birth was Coldra, in the district of Como. He was at first the disciple of Giuseppe d'Arpino, and afterwards of Albano. When he quitted the school of the latter he went to Venice, and studied assiduously the pictures of Titian, Tintoretto, Bassan, and Paolo Veronese. He painted historical subjects and landscapes with great success; but his genius seemed more particularly adapted to the latter. His pictures, in both styles, are spoken of with the warmest commendations. He died in 1665.—He had a brother, Giovanni Battista, who was also a painter, and of some merit, but very inferior to that of the older.

MOLA, (*Mola*, Hebr.) 1. The knee-pan so named, because like a mill-stone. 2. A shapeless mass of flesh in the uterus; a false conception. See MIDWIFERY.

MOLA DI BARI, a town of Naples, in Terra di Bari, on the coast of the gulf of Venice, 12 miles E. of Bari.

MOLA DI GAETA, an ancient town of Naples, in Terra di Bari, seated on the gulf of Venice, 14 miles E. of Bari.

MOLARIS. (from *molaris*, a grindstone, because they grind the food.) A double tooth. See TEETH.

MOLAR GLANDS. *Glandulæ molares.* Two salival glands situated on each side of the mouth, between the masseter and buccinator muscles, and whose excretory ducts open near the last dens molaris.

MOLASSES. See MOLOSSES.

MOLD, a town in Flintshire, where the assizes are held. It is five miles S. of Flint.

MOLDAVIA, a province of Turkey in Europe, 270 miles long and 210 broad; bounded on the N. by Poland, from which it is also divided on the N.E. by the Dniester; on the E. by New Russia; on the S. E. by Bessarabia; on the S. by Bulgaria, from which it is parted by the Danube; on the S.W. by Walachia; and on the W. by Transylvania and Hungary. The other principal rivers are the Pruth, Moldau, and Bardalach. The soil is rich, and it abounds in good pastures, which feed a great number of horses, oxen, and sheep: it also produces corn, pulse, honey, wax, fruits, with plenty of game and fowls. The sovereign, who is styled hospodar, is tributary to the grand seignior. The inhabitants are Christians of the Greek church, and Jassy is the principal town.

MOLDAVIAN BAUM, in botany. See Dracocephalum.

MOLE. *s.* (mœl, Saxon; *mole*, French.) 1. A formless concretion of extravasated blood, which grows into a kind of flesh in the uterus, and is called a false conception (*Quincy*). 2. A natural spot or discoloration of the body (*Pope*). 3. A mound; a dike (*Sandys*). 4. A little beast that works under ground.

Mole, a mountain of Savoy, which, from its height and fine sloping peak, is an object of great beauty when seen from the lake of Geneva. At its foot is the town of Bonneville, 20 miles S. of Geneva.

Mole, a river in Surry, which runs to Darking, and passing beneath Box Hill, is believed to disappear in its vicinity, and to rise again near Leatherhead. Hence it is supposed to derive its name: but the fact is, that a tract of soft ground, two miles in length, called the Swallows, in very dry seasons absorbs the waste water in caverns in the sides of the banks; but not so as to prevent a constant stream from flowing into an open channel above ground. The Mole, proceeding from Leatherhead to Cobham, enters the Thames at E. Moulsey.

Mole (St. Nicholas). See Nicholas, St.

Mole, in mastiology. See Talpa.

Mole-rat, in mastiology. See Mus.

Moles. (*mola.*) In medicine. By this term authors have intended to describe very different productions of, or excretions from, the uterus.

By some it has been used to signify every kind of fleshy substance, particularly those which are properly called polypi; by others, those only which are the consequence of imperfect conception, or when the ovum is in a morbid or decayed state; and by many, which is the most popular opinion, every coagulum of blood which continues long enough in the uterus to assume in form, and to have only the fibrous part, as it has been called, remaining.

There is surely much impropriety, says Dr. Denman, in including under one general name appearances so contrary, and substances so different.

For an account of the first kind, see Polypus.

Of the second kind, which has been defined an *ovum deforme*, as it is the consequence of conception, it might more justly be arranged under the class monsters; for though it has the appearance of a shapeless mass of flesh, if examined carefully with a knife, various parts of a child may be discovered, lying together in apparent confusion, but in actual regularity. The pedicle also by which it is connected to the uterus is not of a fleshy texture, like that of the polypus, but has a regular series of vessels like the umbilical cord, and there is likewise a placenta and membranes containing water. The symptoms attending the formation, growth, and expulsion of this apparently confused mass from the uterus, correspond with those of a well formed child.

With respect to the third opinion of a mole, an incision into its substance will discover its true nature; for although the external surface appears at the first view to be organized flesh, the internal part is composed merely of coagulated blood.

MOLE-CRICKET, in zoology. See Gryllotalpa.

MO'LECAST. *s.* (*mole* and *cast.*) Hillock cast up by a mole (*Mortimer*).

MO'LECATCHER. *s.* (*mole* and *catcher.*) One whose employment is to catch moles.

MO'LEHILL. *s.* (*mole* and *hill.*) Hillock thrown up by the mole working under ground.

Various means have been contrived for extirpating moles, such as irrigating the fields infested with them, &c.; but the most effectual is that described by Dr. Darwin in his Phytologia, and derived from the experience of a successful mole-catcher. This man commenced his operations before the rising of the sun, when he carefully watched their situation; and, frequently observing the motion of the earth above their walks, he struck a spade into the ground behind them, cut off their retreat, and dug them up.

As moles usually place their nests much deeper in the ground than their common habitations are situated, and thus produce an elevation, or a mole-hill, the next step is to demolish such nests by the spade; after which the frequented paths must be distinguished from the by-roads, for the purpose of setting subterraneous traps. This will be effected by marking every new mole-hill with a slight pressure of the foot, and observing the next day whether a mole has passed over it and effaced such mark; which operation must be repeated two or three mornings in succession, but without making an impression so deep as to alarm and induce the animal to open another passage.

The traps must now be set in the frequented paths, and ought to consist of a hollow wooden semicylinder, each end of which should be furnished with grooved rings, containing two nooses of horse-hair, that are fastened loosely in the centre, by means of a peg, and are stretched above the surface of the ground by a bent stick or strong hoop. As soon as the mole passes half way through one of these nooses, and removes the central peg in his course, the curved stick rises in consequence of its elasticity, and thus strangles the animal.

The method above detailed being ingenious, it deserves to be generally adopted; as those whose grounds are infested with moles may easily extirpate them, or teach the art to their labourers. It is, however, in our opinion, an undecided point, whether these little quadrupeds, that live entirely on worms and insects, of which they consume incalculable numbers, are not to be considered as harmless, nay, useful rather than noxious; especially as they have their formidable natural enemies in foxes, martins, weasels, hedge-hogs, serpents, and cats. Farther, it has been observed, that fields and gardens where all the moles had been caught abounded with vermin and insects. But, if these burrowing creatures become too numerous and hurtful to the vegetation of plants, or dangerous to dykes and banks, the most easy method of destroying them is to expose a few living lobsters in a deep-glazed earthen vessel, the top of which is somewhat narrower than its basis, so that they cannot escape: such a pot must be buried several inches deep in the ground, and covered with green sods, so as to be accessible to the mole, which is remarkably partial to that shell-fish. No sooner has one of the former entered the pot, than others from the vicinity will hasten to the fatal receptacle, in consequence of the noise made by the captive; and thus meet with inevitable destruction.

To MOLE'ST. *v. a.* (*molestus*, Latin.) To disturb; to trouble; to vex (*Locke*).

MOLESTA'TION. (*s. molestia*, Latin.) Disturbance; uneasiness caused by vexation (*Brown*).

MOLE'STER. *s.* (from *molest.*) One who disturbs.

MOLESWORTH (Robert), an Irish nobleman and writer, was born at Dublin in 1656. His father was a merchant, and left him a considerable fortune. He married a sister of the earl of Bellamont, and concurred so heartily in the revolution, that king William made him one of his privy-council, and in 1692 sent him envoy-extraordinary to Denmark; but his behaviour proving disagreeable to the Danish monarch, he was forbidden the court, after residing there three years. On this he returned to England, where he wrote his Account of Denmark, which was well received by the public, but gave great offence to the government of that country. George I. made him a commissioner of trade and plantations, and advanced him to the peerage of Ireland in 1716. He died in 1725.

MO'LETRACK. *s.* (*mole* and *track.*) Course of the mole under ground (*Mortimer*).

MO'LEWARP. *s.* (*mold* and ƿeoꞃpan, Sax.) A mole: properly *mouldwarp* (*Drayton*).

MOLIERE (Jean Baptiste, Pocquelin de), a French comic writer, whose real name was Pocquelin, was born at Paris about 1620. He was intended for the business of a tapestry-maker, which was his father's occupation; but his grandfather often taking him to the theatre, the boy conceived so great a disgust to trade that his father allowed him to follow his studies, which he did under the jesuits. When cardinal Richelieu gave his protection to dramatic poets, there were set up several private theatres at Paris, to one of which Moliere attached himself, and then it was that he changed his name. In 1653 he formed a theatrical company, in conjunction with La Bejart, an actress of promising talents, and went to Lyons, where he produced his first play, called L'Etourdi, or the Blunderer. After visiting several places, this company came to Paris, and exhibited before the court in 1658, and were so well approved, that the king took them into his service, and Moliere obtained a pension. His last comedy was, Le Malade Imaginaire, or the Hypochondriac. This piece was acted the fourth time Feb. 17, 1673, and on that day Moliere died. The circumstance of his death was very extraordinary: The chief character in the play is a sick man, who on a certain occasion pretends to be dead; Moliere performed this part, and is said to have died in the exhibition of it. Voltaire says of Moliere, that "he retrieved comedy out of chaos, as Corneille did tragedy."

MOLIERES, a town of France, in the department of Lot, 11 miles N. of Montauban, and 16 S. of Cahors. Lon. 1. 30 E. Lat. 44. 10 N.

MOLINA, a strong town of Spain, in New Castile, seated on the Gallo, in a territory abounding in pasture, 35 miles S.E. of Siguenza, and 88 E.N.E. of Madrid. Lon. 1. 53 W. Lat. 40. 50 N.

MOLINA (Lewis), a Spanish lawyer who was employed by Philip II. king of Spain in the councils of the Indies and of Castile. He is the author of a learned treatise concerning the entails of the ancient estates of the Spanish nobility, entitled, De Hispanorum Primogenitorum Origine et Natura, published in 1603, in folio. This book is likewise applicable to several provinces in France. Lewis Molina must not be confounded with John Molina, a Spanish historian, author of Cronica antiqua d'Arragon, published in 1524, in folio; and also of De las Casas memorables d'Espagna, in folio. The first work appeared at Valencia, and the second at Alcala.

MOLINISTS, in ecclesiastical history, a sect in the Romish church who follow the doctrine and sentiments of the Jesuit Molina, relating to sufficient and efficacious grace. He taught that the operations of divine grace were entirely consistent with the freedom of human will; and he introduced a new kind of hypothesis to remove the difficulties attending the doctrines of predestination and liberty, and to reconcile the jarring opinions of Augustines, Thomists, Semi-Pelagians, and other contentious divines. He affirmed that the decree of predestination to eternal glory was founded upon a previous knowledge and consideration of the merits of the elect; that the grace, from whose operation these merits are derived, is not efficacious by its own intrinsic power only, but also by the consent of our own will, and because it is administered in those circumstances in which the Deity, by that branch of his knowledge which is called *scientia media*, foresees that it will be efficacious. The kind of prescience, denominated in the schools *scientia media*, is that foreknowledge of future contingents that arises from an acquaintance with the nature and faculties of rational beings, of the circumstances in which they shall be placed, of the object that shall be presented to them, and of the influence which their circumstances and objects must have on their actions.

MOLINÆA, in botany, a genus of the class octandria, order monogynia. Calyx five-parted; corol five-petalled; filaments villous at the base; styleless; capsule three-celled, three-valved; the cells one-seeded. Three species, indigenous to the isle of Bourbon, and the East Indies.

MOLISE, a territory of Naples, in the form of a triangle, whose sides are 39 miles long, lying between Terra di Lavoro, Abruzzo Citeriore, Capitaneta, and Principato Ulteriore. It is a mountainous country, but fertile in corn, wine, saffron, and silk.

Molise, a town of Naples, capital of a territory of the same name, but not populous. It is 50 miles N. of Naples. Lon. 14. 43 E. Lat. 41. 36 N.

MOLLE *Soft* or *Sweet.* In music, a relative term used by the French, signifying a flat sound; that is, a sound which is half a tone lower than the sound with which it is compared: as B flat, or B molle, is a semitone beneath B natural, or B durum. This term, as its sense intimates, is applied to the flat sounds on account of their supposed softness or sweetness in comparison with the effect of the natural and sharp tones.

MO'LLIENT. *a.* (*molliens*, Latin.) Softening.

MO'LLIFIABLE. *a.* (from *mollify.*) That may be softened.

MOLLIFICA'TION. *s.* (from *mollify.*) 1. The act of mollifying or softening (*Bacon*). 2. Pacification; mitigation (*Shakspeare*).

MO'LLIFIER. *s.* (from *mollify.*) 1. That which softens; that which appeases (*Bacon*). 2. He that pacifies or mitigates.

To MO'LLIFY. *v. a.* (*mollio*, Latin.) 1. To soften; to make soft. 2. To assuage (*Isaiah*). 3. To appease; to pacify; to quiet (*Spenser*). 4. To qualify; to lessen any thing harsh or burdensome (*Clarendon*).

MOLLITIES OSSIUM. (*Mollities*, from *mollis*, soft.) A disease of the bones, in which they can be bent without fracturing them.

Mollities unguinum. A preternatural softness of the nails that often accompanies chlorosis.

MOLLOY (Charles, Esq.), descended from a good family in the kingdom of Ireland, was born in the city of Dublin, and received part of his education at Trinity college there, of which he afterwards became a fellow. At his first coming to England he entered himself of the Middle Temple, and was supposed to have had a very considerable hand in the writing of a periodical paper called Fog's Journal; as also since that time to have been almost the sole author of another well known paper, entitled Common Sense. All these papers give testimony of strong abilities, great depth of understanding, and clearness of reasoning. Dr. King was a considerable writer in the latter, as were lords Chesterfield and Lytelton. Our author had large offers made him to write in defence of sir Robert Walpole, but these he rejected: notwithstanding which, at the great change of the ministry in 1742, he was entirely neglected, as well as his fellow-labourer Amherst, who conducted The Craftsman. Mr. Molloy, however, having married a lady of fortune, was in circumstances which enabled him to treat the ingratitude of his patriotic friends with the contempt it deserved. He lived many years after this period, dying so lately as July 16, 1767. He also wrote three dramatic pieces, viz. The Perplexed Couple; The Coquet; and The Half-pay Officers; none of which met with much success.

MOLLUCELLA, in botany, a genus of the class didynamia, order gymnospermia. Calyx campanulate, dilated, broader than the corol, spinous. Six species, natives of the Molucca islands, Syria, and Tartary; some of them shrubs, others annual herbaceous plants.

MOLLUGO, African chickweed, in botany, a genus of the class triandria, order trigynia. Calyx five-leaved: corolless; capsule three-celled, three-valved. Six species, natives of the East Indies, South America, and the Cape.

MOLLUSCA, in zoology, the second order of the Linnéan class vermes; they are naked, simple animals, not included in a shell; furnished with tentacles or arms; for the most part inhabitants of the sea; by their natural phosphorescence they illuminate in a considerable degree the dark abyss of waters, and often reflect their corruscations to the firmament. See Zoology and Vermes.

MOLOCH, a false god of the Ammonites, who dedicated their children to him, by making them "pass through the fire," as the scriptures express it. There are various opinions concerning this method of consecration. Some think the children leaped over a fire sacred to Moloch; others, that they passed between two fires; and others, that they were really burnt in the fire, by way of sacrifice to this god. There is foundation for each of these opinions. For, first, it was usual among the pagans to lustrate or purify with fire; and, in the next place, it is expressly said, that the inhabitants of Sepharvaim burnt their children in the fire to Anamelech and Adramelech; much such deities as Moloch of the Ammonites.

Moses, in several places, forbids the Israelites to dedicate their children to this god as the Ammonites did, and threatens death and utter extirpation to such persons as were guilty of this abominable idolatry. And there is great probability that the Hebrews were much addicted to the worship of this deity; since Amos, and after him St. Stephen, reproaches them with having carried along with them into the wilderness the tabernacle of their god Moloch.

Solomon built a temple to Moloch upon the mount of Olives; and Manasseh, a long time after, imitated his impiety by making his son pass through the fire in honour of Moloch. It was chiefly in the valley of Tophet and Hinnom, to the east of Jerusalem, that the Israelites paid their idolatrous worship to this false god of the Ammonites.

There are various sentiments concerning the relation which Moloch had to the other pagan divinities. Some believe he was the same with Saturn, to whom it is well known that human sacrifices were offered. Others suppose him to be Mercury; others, Mars; others, Mithras; and others, Venus. Lastly, others take Moloch to be the sun, or the king of heaven. Moloch was likewise called Milkom; as appears from what is said of Solomon, that he went after Ashtaroth the abomination of the Zidonians, and Milkom the abomination of the Ammonites.

MOLORCHUS, an old shepherd near Cleonæ, who received Hercules with great hospitality. The hero, to repay the kindness he received, destroyed the Nemæan lion, which laid waste the neighbouring country, and therefore the Nemæan games instituted on this occasion are to be understood by the words *Ludus Molorchi*. There were two festivals instituted in his honour called Molorcheæ.

Molorchus, in the Fabrician system of entomology, a tribe of the genus Necydalis, which see.

MOLOSSES, Molasses, or Melasses, that gross fluid matter remaining of sugar after refining, and which no boiling will bring to a consistence more solid than that of syrup; hence also called syrup of sugar. Properly, molosses are only the sediment of one kind of sugar called chypre, or brown sugar, which is the refuse of other sugars not to be whitened or reduced into loaves. Molosses are much used in Holland for the preparation of tobacco, and also among poor people instead of sugar. There is a kind of brandy or spirit made of molosses; but by some held exceedingly unwholesome. See below.

Molosses spirit; a very clean and pure spirit, much used in England, and made from molosses or common treacle dissolved in water, and fermented in the same manner as malt or the common malt-spirit. (See Distillation.) Molosses spirit coming dearer than that of malt, it is frequently met with basely adulterated with a mixture of that spirit, and indeed seldom is to be bought without some dash of it. Many have a way of mixing malt in the fermenting liquor; by this the yield of the whole is greatly increased, and the maker may assure the buyer that the spirit is pure as it ran from the worm. In most of the nice cases in our compound distillery the molosses spirit supplies the place of a pure and clean spirit. Our cinnamon, citron, and other fine cordial waters, are made with it; for the malt spirit would impart to these a very disagreeable flavour. Molosses spirit, it is possible, the vinegar-makers may find use for; but the most advantageous of all its uses is to the distiller himself; a quantity of it added to new treacle intended for fermentation will be of great use in the process, and increase very considerably the quantity of spirit; but the proportion in regard to the new matter must not be too great.

MOLOSSI, a people of Epirus, who inhabited that part of the country which was called Molossia or Molossus, from king Molossus, a son of Pyrrhus and Andromache. This country had the bay of Ambracia on the south, and the country of the Perrhæbeans on the east. The dogs of the place were famous, and received the name of Molossi among the Romans.—Dodona was the capital of the country, according to some writers. Others, however, reckon it as the chief city of Thesprotia.

MOLOSSUS, a son of Pyrrhus and Andromache. He reigned in Epirus after the death of Helenus, and part of his dominions received the name of Molossia from him. (*Paus.*)

Molossus, in the Greek and Latin poetry, a foot consisting of three long syllables. As, *audiri, cantabant, virtutem*. It takes its name either from a dance in use among the people called Molossi or Epirotæ; or from the temple of Jupiter Molossus, where odes were sung, in which this foot had a great share.

MOLSHEIM, a town in France, in the department of Lower Rhine, seated on the Brusch, 10 miles W. by S. of Strasburg, and 228 E. of Paris. Lon. 7. 35 E. Lat. 48. 32 N.

MOLTEN. The part. pass. from *melt*.

Molten grease, called also Morfounder, or Body founder. In veterinary language, a disease produced by too great, sudden, or powerful exertions, when a horse is not in proper condition: as in strong and severe hunting, long and speedy journeys, or hard driving in carriages, when the animal has been just taken from grass loaded with impurities; just out of a dealer's possession, full of light flatulent food; or when naturally too full of flesh for violent exercise. "In such cases," says Taplin, "from the internal heat, increased circulation, and temporary inflammation, the fat seated upon the membranes in various parts of the body undergoes rarefaction and rapid solution, making distinct efforts for discharge by the different emunctories. The proportion nearest the vessels becomes absorbed, and there is produced some degree of fever; another part makes its appearance in the excrements; a third portion fixes upon the lungs, and obstructs respiration; to these a laxation of the intestinal contents succeeds; and, lastly, a looseness, or scouring; so that in the present instance we plainly perceive the possibility of almost a complication of disorders originating in a single cause, and the foundation of that cause—indiscretion.

"A little reflection upon the incontrovertible truth of this observation will surely point out to every humane master and faithful servant the great danger of over-riding, driving, or fatiguing any horse whatever beyond what is prudent and necessary; especially when not in high condition for the service he may be engaged in, whether on the turf, field, or road. Let it be constantly held in remembrance, more horses are ruined and destroyed by cruelty and neglect than by chance or accident. The subject we now treat on proves, more than any other, the absolute necessity of insuring condition previous to a course of constant business." See CONDITION.

The symptoms, observes the same writer, are in different subjects more or less violent, according to their state and condition at the time of attack; varying in all in proportion to the parts most affected by the original cause. "Wherever the solution has proved most partial, the effect will become most predominant; as, for instance, upon the bowels, lungs, or circulation of the blood by absorption. In the first, great pain attends the laxation or looseness; in the second, great difficulty of breathing from the expansion of the lungs may produce symptoms of inflammation there. And when the mass of blood is generally affected, and preternaturally loaded, fever must consequently ensue. These symptoms, as before observed, all vary in different subjects; but one is pathognomonic or invariable in all, which is the general incorporation of a greasy substance with the excrements, nearly similar to the separated particles of congealed oil in frosty weather; previous to the entire solution of the intestinal contents, and so long as the dung retains its usual form, the greasy hue appears only upon the surface, but as it advances in disease it becomes more intimately united.

"So soon as ever these symptoms are perceived, proper methods should be taken to relieve nature from the threatening oppression, by such evacuations as the predominant circumstances direct; at any rate let plentiful bleeding be the first step to reduce present, or prevent approaching, inflammation. If fever have not come on too rapidly, give, as soon as circumstances will permit, mild laxative drinks; and more powerful if the strength of the horse will allow it.

"To attenuate the blood, relieve the lungs, and take off the load from the circulation, as well as to mitigate all symptoms of fever (if such there are), adopt a cooling plan of treatment, with the assistance of bran water or pectoral decoction, especially if the lungs are much oppressed, or the approach of inflammation apprehended. The appetite must also be attended to, and solicited in every stage of the disease by comfortable mashes."

As soon as the predominant symptoms subside, Mr. Taplin recommends to proceed to a course of mild purging balls, going regularly through three doses, at such periods as are best adapted to the strength of the horse. In a few days, after working off the last dose too, we are instructed to begin upon warm diuretics, well guarded with aromatics, giving one every morning for a fortnight.

"The work begun by the alterative purges will be completed by the gradual effects of the diuretics; and, with proper attention to the rules laid down, the horse may be soon produced in good state and condition."

The foregoing account of this singular disease is conformable to that of Gibson, Bracken, Wood, and other veterans of the old school. Mr. John Lawrence also repeats their account of it, accords principally with their treatment, and asserts that he has "repeatedly seen it, though not in any very dangerous form;" nay, that when a boy he was the occasion of it in a horse encumbered with flesh and fat, having ridden him hard in hot weather. It is worthy of remark, however, that the latest veterinary writers have taken no notice of this disease, or at least have declined treating of it under the unscientific and vague appellation of molten (i. e. melted) grease. Chemical tests applied to this matter discharged from the intestines would readily decide the question as to its real nature; which, instead of fat, we rather suspect to be the coagulable lymph of the blood, transuded through the coats of the intestines, or else a redundancy of their natural mucus.

MOLTO. (Ital.) Very, or Much. A word used in music, in conjunction with some other, by way of augmentation; as, *molto allegro*, very quick; *molto adagio*, very slow.

MOLUCCA ISLANDS, islands in the Eastern Indian Sea. These valuable islands, strictly speaking, consist of no more than five: viz. Ternate, Timor, or Motir, Tydor, Machian, and Bachian; but Amboyna, Bourso, Ceram, and several others, are now included in the name of Moluccas. The five former are not out of sight of each other, and lie all of them within the compass of twenty-five leagues. They are famous for producing several sorts of valuable spices, but especially nutmegs and cloves, and are under the dominion of three kings. Their coasts are rendered very dangerous by sands and shelves. They were formerly subject to the Chinese, fell next under the Javanese, were, in process of time, subdued by the Malayans; and the Mahometans had begun to settle in them, and convert the inhabitants to their religion but a very little while before they were discovered by the Portuguese. Their chief riches consist in cloves: they have extraordinary parrots, which exceed in beauty those of the West Indies: and many birds of paradise. They have also almonds, and coarse tobacco. During their wars with the Portuguese, they burnt all their clove-trees, retired to the mountains and deserts, and forbad selling any thing to that nation on pain of death: a prohibition which reduced them to great extremity. Though they burnt the cloves out of despair, their ashes so enriched the soil that it produced cloves in greater abundance than ever in a few years. Many of these islands had their particular kings, but all subject to the king of Ternate; and they served under him to revenge the death of king Aerio, who was treacherously murdered by the Portuguese. — This great king's name was Cachil Babu, Aerio's third son. He allowed the Dutch to trade here; in 1599 entered into a strict friendship with them, and they assisted him to shake off the yoke of the Spaniards and Portuguese.

MOLUCCENSE LIGNUM. See Lignum Pavanae.

MOLY, in botany. See Allium.

MOLYBDATS. (*molybdas*). Salts formed by the union of the molybdic acid with different bases: thus, molybdat of alumin, molybdat of antimony, &c.

Molybdat of lead. See Plumbum.

MOLYBDÆNUM, in mineralogy, a genus of the class metals. Blueish grey, not tarnishing, brittle, not magnetic, composed of scaly particles cohering together; specific gravity 7,500; nearly infusible, gradually becoming a white, volatile oxyd when heated, which with borax forms a violet, and with microcosmic salt a green glass; partly soluble in sulphuric acid, and giving the solution a green and then a blue colour. One species only; M. vulgare, common molybdænum; molybdæna; molybdenite; sulphurised molybdæna, Schmeisser; sulphuret of molybdæna, Thomson; wasserbley, Werner. Found in France, Spain, Sweden, Saxony, Siberia, and Iceland, in gangues of feldspar, lithomarge, or quartz, generally in masses consisting of small grains agglutinated together, sometimes crystallised in six-sided tables; colour light lead-grey, with sometimes a shade of red; streak blueish-grey, metallic; powder blueish; soft, opake, staining the fingers, and feeling a little greasy to the touch; texture lamellar, with the foliations thin, incurved, and slightly flexible: with warm nitric acid it effervesces, leaving a grey oxyd undissolved; before the blow-pipe it evaporates in white sulphureous vapours; specific gravity from 4,569 to 4,738; contains,

Molybdænum - - - - -	60
Sulphur - - - - - - -	40
	100

The yellow lead ore, or molybdat of lead, as it is called by Thomson, seems rather to be a species of lead than of molybdænum, and will hence be found arranged under the article Plumbum.

From the experiments of Mr. Hatchet, it follows that molybdænum is capable of combining with four different proportions of oxygen, and of forming four oxyds; namely, 1. The black; 2. the blue; 3. the green, to which Mr. Hatchet has given the name of molybdous acid; and, 4. the yellow or white, or the molybdic acid.

1. The protoxyd, or black oxyd, may be obtained by mixing molybdic acid with charcoal powder in a crucible, and applying heat. A black mass remains, which is the black oxyd. It seems to contain only a very minute quantity of oxygen.

2. The blue oxyd may be obtained by the same process not carried so far: it is formed also whenever a plate of tin is plunged into a solution of molybdic acid.

3 The peroxyd is obtained by distilling six parts of diluted nitric acid repeatedly off native molymbdena in powder. A white mass is left behind, composed of sulphuric and molybdic acids. A little pure water washes away the sulphuric acid, and molybdic acid remains behind. This acid has at first a white colour; but when melted and sublimed it becomes yellow.

Molybdænum combines readily with sulphur; and the compound has exactly the properties of molybdæna, the substance which Scheele decompounded. Molymbdæna is therefore sulphuret of molybdenum. The reason that Scheele obtained from it molybdic acid was, that the metal combined with oxygen during his process. Sulphuret of molybdænum may be formed also by distilling together one part of molybdic acid and five parts of sulphur. Molybdenum is also capable of combining with phosphorus.

Few of the alloys of this metal have been hitherto examined.

It seems capable of uniting with gold. The alloy is probably of a white colour. It combines readily with platinum in the state of an oxyd. The compound is fusible. Its specific gravity is 20,000.

The alloys of molybdenum with silver, iron, and copper, are metallic and friable; those with lead and tin are powders which cannot be fused. Several other combinations have been made both by Hielm and Richter; but as the metals which they tried were alloyed not with molybdænum, but with molymbdic acid, they cannot be considered as by any means the same with the alloys formed by molybdænum itself.

Assay and *Analysis.*—The most usual way of decomposing the sulphuret of molybdæna is by detonation with nitre: but by this means the molybdic acid becomes so intimately combined with pot-ash as to render it extremely difficult by subsequent operations to obtain. The best method of proceeding therefore appears to be the following.

a. To one part of finely pulverized molybdæna add four or five parts of moderately diluted nitric acid, and distil the mixture nearly to dryness: then return the contents of the receiver into the retort, add some more nitric acid, and proceed a second time to distillation: repeat this for three or four times till the insoluble matter in the retort is as white as chalk. Then pour off the supernatant fluid, and wash the white matter repeatedly in warm water, adding the washings to the other fluid.

b. Evaporate the residual fluid to a moderate degree of concentration, and then pour in ammonia: the first portions will occasion a precipitation; but by adding more ammonia and assisting the process by a gentle warmth, the whole precipitate will be re-dissolved: then drop in strong nitric acid to complete the saturation of the alkali, and a white precipitate will fall down, which is to be separated by the filter, and washed in warm water.

c. The residual fluid with the washings being mixed together now contains ammonia combined with nitric and sulphuric acids, the latter of which arises from the oxygenation of the sulphur in the ore. Nitrat of baryte being dropped in, a precipitation of sulphated baryte takes place, from the amount of which the quantity of sulphur in the ore is readily inferred.

d. The white matter obtained in processes *a* and *b*, which is molybdic acid with a little oxyd of iron, must now be dissolved in strong sulphuric acid, and the solution subsequently diluted with 16 times its weight of water: ammonia being now cautiously added to perfect saturation, the iron will gradually fall down in the state of yellow oxyd.

e. The clear liquor of the preceding process being evaporated to dryness, the salt thus procured is to be strongly treated in a glass vessel till all the sulphat of ammonia is expelled: what remains behind is a black blistered mass, which by abstraction with nitric acid is converted into a yellow powder, which is pure molybdic acid.

The only material objection to this method of analysis is that the molybdæna exists in its metallic state in the ore, but is obtained in the analysis in the state of acid: and as the amount of oxygen in molybdic acid has not yet been ascertained, this analysis is at best only an approximation to a true knowledge of the ingredients of the ore, so long as we remain ignorant of the composition of molybdic acid.

Neither the metal nor any of its preparations have hitherto been made use of.

MOLYBDENITE. See MOLYBDÆNUM.

MOLYNEUX (William), an excellent mathematician and astronomer, was born at Dublin in 1656. After the usual grammar education, which he had at home, he was entered of the university of that city. Here he distinguished himself by the probity of his manners, as well as by the strength of his parts; and having made a remarkable progress in academical learning, and particularly in the new philosophy, as it was then called, after four years spent in this university, he was sent over to London, where he was admitted into the Middle Temple in 1675. Here he spent three years, in the study of the laws of his country. But the bent of his genus lay strongly toward mathematical and philosophical studies; and even at the university he conceived a dislike to scholastic learning, and fell into the methods of lord Bacon.

Returning to Ireland in 1678, he shortly after married Lucy the daughter of sir William Domville, the king's attorney-general. Being master of an easy fortune, he continued to indulge himself in prosecuting such branches of natural and experimental philosophy as were most agreeable to his fancy; in which astronomy having the greatest share, he began, about 1681, a literary correspondence with Mr. Flamsteed, the king's astronomer, which he kept up for several years. In 1683 he formed a design of erecting a Philosophical Society at Dublin, in imitation of the Royal Society at London; and, by the countenance and encouragement of sir William Petty, who accepted the office of president, began a weekly meeting that year, when our author was appointed their first secretary.

Mr. Molyneux's reputation for learning recommended him, in 1684, to the notice and favour of the first great duke of Ormond, then lord lieutenant of Ireland; by whose influence chiefly he was appointed that year, jointly with sir William Robinson, surveyor-general of the king's buildings and works, and chief engineer.

In 1685, he was chosen fellow of the Royal Society at London; and that year he was sent by the government to view the most considerable fortresses in Flanders. Accordingly he travelled through that country and Holland, with part of Germany and France; and carrying with him letters of recommendation from Flamsteed to Cassini, he was introduced to him, and others, the most eminent astronomers in the several places through which he passed.

Soon after his return from abroad, he printed at Dublin, in 1686, his Sciothericum Telescopium, containing a Description of the Structure and use of a Telescopic Dial, invented by him: another edition of which was published at London in 1700.

In 1688 the Philosophical Society of Dublin was broken up and dispersed by the confusion of the times. Mr. Molyneux had distinguished himself as a member of it from the beginning, and presented several discourses upon curious subjects; some of which were transmitted to the Royal Society at London, and afterwards printed in the Philosophical Transactions. In 1689, among great numbers of other Protestants, he withdrew from the disturbances in Ireland, occasioned by the severities of Tyrconnel's government; and after a short stay at London he fixed himself with his family at Chester. In this retirement he employed himself in putting together the materials he had some time before prepared for his Dioptrics, in which he was much assisted by Mr. Flamsteed; and in August 1690, he went to London to put it to the press, where the sheets were revised by Dr. Halley, who, at our author's request, gave leave for printing, in the appendix, his celebrated Theorem for finding the Foci of Optic Glasses. Accordingly the book came out, 1692, in 4to, under the title of Dioptrica Nova: a Treatise of Dioptrics, in two parts; wherein the various effects and appearances of spherical glasses, both convex and concave, single and combined, in telescopes and microscopes, together with their usefulness in many concerns of human life, are explained." He gave it the title of Dioptrica Nova, both because it was almost wholly new, very little being borrowed from other writers, and because it was the first book that appeared in English upon the subject. The work contains several of the most generally useful propositions for practice, demonstrated in a clear and easy manner, for which reason it was for many years used by the artificers: and the second part is very entertaining, especially in the history which he gives of the several optical instruments, and of the discoveries made by them.

Before he left Chester he lost his lady, who died soon after she had brought him a son. Illness had deprived her of her eye-sight 12 years before, that is, soon after her marriage; from which time she had been very sickly, and afflicted with great pains in her head.

As soon as the public tranquillity was settled in his native country, he returned home; and, upon the convening of a new parliament in 1692, was chosen one of the representatives for the city of Dublin. In the next parliament, in 1695, he was chosen to represent the university there, and continued to do so to the end of his life; that learned body having lately conferred on him the degree of doctor of laws. He was likewise nominated by the lord-lieutenant one of the commissioners for the forfeited estates, to which employment was annexed a salary of 500l. a year; but looking upon it as an invidious office, he declined it.

In 1698, he published The Case of Ireland stated, in regard to its being bound by acts of Parliament made in England: in which it is supposed he has delivered all, or most, that can be said upon this subject, with great clearness and strength of reasoning.

Among many learned persons with whom he maintained correspondence and friendship, Mr. Locke was in a particular manner dear to him, as appears from their letters. In the above mentioned year, which was the last of our author's life, he made a journey to England, on purpose to pay a visit to that great man; and not long after his return to Ireland, he was seized with a fit of the stone, which terminated his existence.

Besides the three works already mentioned, viz. the Sciothericum Telescopium, the Dioptrica Nova, and the Case of Ireland stated; he published a great number of pieces in the Philosophical Transactions, which are contained in the volumes 14, 15, 16, 18, 19, 20, 21, 22, 23, 26, 29, several papers commonly in each volume.

Molyneux (Samuel), son of the former, was born at Chester in July 1689; and educated with great care by his father, according to the plan laid down by Locke on that subject. When his father died, he fell under the management of his uncle, Dr. Thomas Molyneux, an excellent scholar and physician at Dublin, and also an intimate friend of Mr. Locke, who executed his trust so well, that Mr. Molyneux became afterwards a most polite and accomplished gentleman, and was made secretary to George the 3d when prince of Wales. Astronomy and optics being his favourite studies, as they had been his father's, he projected many schemes for the advancement of them, and was particularly employed in the years 1723, 1724, and 1725, in perfecting the method of making telescopes; one of which instruments, of his own making, he had presented to John the 5th, king of Portugal.

Being soon after appointed a commissioner of the admiralty, he became so engaged in public affairs, that he had not leisure to pursue those enquiries any farther, as he intended. He therefore gave his papers to Dr. Robert Smith, professor of astronomy at Cambridge, whom he invited to make use of his house and apparatus of instruments, in order to finish what he had left imperfect. But Mr. Molyneux dying soon after, Dr. Smith lost the opportunity; he however supplied what was wanting from M. Huygens and others, and published the whole in his Complete Treatise of Optics.

MOMBAZA, or **Monbaza**, a town of Africa, in an island of the same name, with a castle and a fort; seated on the eastern coast, opposite to the country of Mombaza in Zanguebar, 70 miles south of Melinda, and subject to Portugal. Lon. 48. 0 E. Lat. 44. 0 N.

Mombaza, a country of Africa in Zanguebar, subject to the Portuguese, from whence they export slaves, gold, ivory, rice, flesh, and other provisions, with which they supply the settlements in Brasil. The king of this country being a Christian, had a quarrel with the Portuguese governor, took the castle by assault, turned Mahometan, and murdered all the Christians, in 1631; but in 1720 they became masters of the territory again.

MOME. *s.* A dull, stupid blockhead; a stock; a post (*Shakspeare*).

MO'MENT. *s.* (*moment*, Fr. *momentum*, Lat.) 1. Consequence; importance; weight; value (*Bentley*). 2. Force; impulsive weight; actuating power (*Ben Jonson*). 3. An indivisible particle of time (*Prior*).

Moment, in time, is sometimes taken for an extremely small part of duration; but, more properly, it is only an instant or termination or limit in time, like a point in geometry. Maclaurin's Fluxions, vol. 1, pa. 245.

Moments, in the new doctrine of infinites, denote the indefinitely small parts of quantity; or they are the same with what are otherwise called infinitesimals, and differences, or increments and decrements; being the momentary increments or decrements of quantity considered as in a continual flux.

Moments are the generative principles of magnitude: they have no determined magnitude of their own; but are only inceptive of magnitude.

Hence, as it is the same thing, if, instead of these moments, the velocities of their increases and decreases be made use of, or the finite quantities that are proportional to such velocities; the method of proceeding which considers the motions, changes, or fluxions of quantities, is denominated, by sir Isaac Newton, the Method of Fluxions.

Moment, in the doctrine of statics, denotes the product of any force into the perpendicular distance of its direction from the body on which it acts.

MOME′NTALLY. *ad.* (from *momentum*, Lat.) For a moment (*Browne*).

MOMENTA′NEOUS. Mo′mentany. *a.* (*momentaneus*, Lat. *momentanie*, French.) Lasting but a moment (*Bacon*).

MO′MENTARY. *a.* (from *moment.*) Lasting for a moment; done in a moment (*Dryden*).

MO′MENTOUS. *a.* (from *momentum*, Latin.) Important; weighty; of consequence (*Addison*).

MOMENTUM, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity. See Force, Quantity of motion, and Dynamics.

MOMO′RDICA. Male balsam apple. In botany, a genus of the class monoecia, order triandria. Male: calyx five-cleft; coral five-parted, filaments three; anthers cohering. Fem. calyx five-cleft; corol five-parted; styles three-cleft; pome opening elastically, three-celled. Eight species: the following are the chief.

1. M. balsamina. Common balsam apple. Fruit angular, tubercled; leaves glabrous, deeply cut in a spreading palmate manner, trailing melon-like stem, sending out many side-branches with tendrils. A native of India, flowering in June and July. The Indians employ it as a vulnerary; for which purpose they cut open the unripe fruit, and infuse it in sweet oil, which they expose to the sun for some days till it acquires a red colour. The oil thus prepared is applied to wounds by being dropped on cotton, and is esteemed the best traumatic next to the balsam of Mecca.

2. M. charantia. Hairy momordica. Fruit angular, tubercled, white, yellow or green on the outside; within, very red and fleshy, one-celled, bursting elastically: a native of the East Indies; flowers in June and July.

3. M. luffa. Egyptian momordica. Fruit oblong, hairy, with chain-like angles, three-celled, with a white flaccid esculent pulp, of an insipid flavour. A native of Arabia and the East Indies: flowers in July and August.

4. M. elaterium. Elastic momordica. Officinal elaterium. Fruit oblong, smooth, bristly: does not change its colour; but when ripe quits the peduncle, and casts out the seeds and juices with great violence. It is the dried juice of the fruit that forms the elaterium of the shops, and is the most powerful cathartic in the whole materia medica. See Elaterium and Cucumis agrestis.

All these plants may be propagated by sowing the seeds in hot-beds in the same manner as cucumber-seeds; and they require the same attention as the cucumber plant afterwards. The first three sorts are ornamental stove plants; the last will thrive in open borders.

MOMOTUS. Motmot. In zoology, a genus of the class aves, order picæ. Bill strong, slightly curved, serrate at the edges; nostrils feathered, tongue feathered; tail wedged, feet gressorial. One species only, M. Brasiliensis, Brasilian motmot, affording two varieties. The one is ornamented with a bright green above, below with a more obscure shade of the same colour: size that of a pie, or about seventeen inches from the tip of the bill to that of the tail: bill conic, bent a little downwards, and serrated upon the edges of both mandibles: toes three before and one behind; fore-toes closely united almost the whole length. The other variety differs more considerably in its colours. Both are distinguished from all other birds by having the two middle feathers of the tail quite naked of their vanes for about an inch, at a small distance from their extremity.

Some have imagined that this nakedness of the feathers of the tail of this bird was not the production of nature, but was owing to the caprice of the animal in tearing away the vanes from that part of the stalk which is seen bare. In the young of this genus, however, naturalists have observed that the vanes of these feathers are quite entire, and that, as they advance to their adult state, they gradually grow shorter and shorter, till at last, in old age, they altogether disappear.

These birds inhabit South America: they are very difficult to tame, because they live upon insects, which cannot easily be procured suitable to their taste. They are extremely shy and timid when old; and, if then in captivity, invariably refuse all kinds of food. From their solitary habits, they never go in flocks, nor even in pairs; and are hardly ever seen but in the midst of large forests, where they hop among the lower branches, or upon the ground. They are almost altogether incapable of flight, and therefore generally build their nests upon the ground in the deserted holes of some of the smaller quadrupeds. The nest consists of a few withered blades of grass, on which they deposite their eggs to the number of two. These birds are described by Edwards under the name of Brasilian saw-billed rollers; and by Marcgrave in his Natural History of Brasil they are called guira-guainumbi.

MOMUS, the god of pleasantry among the ancients, son of Nox, according to Hesiod. He was continually employed in satirizing the gods, and whatever they did was freely turned into ridicule. Vulcan, Minerva, Venus, &c. all alike experienced the shafts of his censure and ridicule. Such liberal reflections, however, upon the gods were the cause that Momus was driven from heaven. He is generally represented raising a mask from his face, and holding a small figure in his hand.

MONA, an island between Britain and Hibernia, anciently inhabited by a number of Druids. It is supposed by some to be the modern island of Anglesey, and by others the island of Man.

Mona, an island of the Baltic Sea, south-west of the island of Zealand, subject to Denmark. Lon. 12. 30 E. Lat. 55. 20 N.

Mona: See Inchcolm.

MO'NACHAL. *a.* (*monacal*, French.) Monastic; relating to monks, or conventual orders.

MO'NACHISM. *s.* (*monachisme*, French.) The state of monks; the monastic life.

MO'NACO, a small but handsome and strong town of Italy, in the territory of Genoa, with a castle, citadel, and a good harbour. It is seated on a craggy rock, and has its own prince, under the protection of France. Lon. 7. 33 E. Lat. 43. 48 N.

MO'NAD. Mo'nade. *s.* (μονὰς.) An indivisible thing. See Leibnitzian philosophy.

MONADELPHIA. (μονος and αδελφος, one brotherhood.) The name of the sixteenth class in the Linnéan system of botany. Comprehending those plants which have hermaphrodite flowers, with one set of united stamens. They form a natural class, entitled columniferæ.

MONAGHAN, a county of Ireland, situated in the province of Ulster, is bounded by Tyrone on the north, Armagh on the east, Cavan and Louth on the south, and Fermanagh on the west. It is a boggy and mountainous tract, but in some places is well improved. It contains 170,090 Irish plantation acres, 24 parishes, five baronies, and one borough, and sends four members to parliament. It is about 30 miles long and 22 broad. The linen trade of this county is averaged at 104,000l. yearly.

Monaghan, a post, fair, and market town, and chief of the county of that name, is distant 62 miles from Dublin; it is a borough, and returns two members to parliament; patron lord Clermont. It gives title of baron to the family of Blayney, and has six fairs. It was anciently called Muinechan. An abbey was founded here in a very early age, of which Moelodius the son of Aodh was abbot. In 1462 a monastery for conventual Franciscans was erected on the site of this abbey, which was granted on the general suppression of monasteries to Edward Withe, and a castle has been since erected on the site by Edward lord Blayney.

MONAMY (P.), a good painter of sea-pieces, was born in Jersey; and certainly (says Mr. Walpole), from his circumstances, or the views of his family, he had little reason to expect the fame he afterwards acquired, having received his first rudiments of drawing from a sign and house painter on London-bridge. But when nature gives real talents, they break forth in the homeliest school. The shallow waves that rolled under his window taught young Monamy what his master could not teach him, and fitted him to imitate the turbulence of the ocean. In Painters' hall is a large piece by him, painted in 1726. He died at his house in Westminster the beginning of 1749.

MONANDRIA. (from μονος, alone, and ανηρ, a man or husband.) The name of the first class in the Linnéan system of botany, comprehending those plants which have only one stamen in a hermaphrodite flower.

MO'NARCH. *s.* (μόναρχος.) 1. A governour invested with absolute authority; a king (*Temple*). 2. One superiour to the rest of the same kind. 3. President (*Shakspeare*).

MONA'RCHAL. *a.* (from *monarch.*) Suiting a monarch; regal; princely; imperial (*Milton*).

MONA'RCHICAL. *a.* (μόναρχικὸς.) Vested in a single ruler (*Brown*).

To MO'NARCHISE. *v. n.* (from *monarch.*) To play the king (*Shakspeare*).

MONARCHY, a large state governed by one; or a state where the supreme power is lodged in the hands of a single person. The word comes from the Greek μοναρχης, one who governs alone; formed of μονος, *solus*, and αρχη, *imperium*, government." Of the three forms of government, viz. democracy, aristocracy, and monarchy, the last is the most powerful, all the sinews of government being knit together, and united in the hand of the prince; but then there is imminent danger of his employing that strength to improvident or oppressive purposes. As a democracy is the best calculated to direct the end of a law, and an aristocracy to invent the means by which that end shall be obtained, a monarchy is most fit for carrying those means into execution.

The most ancient monarchy was that of the Assyrians, which was founded soon after the deluge. We usually reckon four grand or universal monarchies; the Assyrian, Persian, Grecian, and Roman; though St. Augustine makes them but two, viz. those of Babylon and Rome. Belus is placed at the head of the series of Assyrian kings who reigned at Babylon, and is by profane authors esteemed the founder of it, and by some the same whom the scriptures call Nimrod. The principal Assyrian kings after Belus were, Ninus, who built Nineveh, and removed the seat of empire to it; Semiramis, who, disguising her sex, took possession of the kingdom instead of her son, and was killed, and succeeded by her son Ninyas; and Sardanapalus, the last of the Assyrian monarchs, and more effeminate than a woman. After his death the Assyrian empire was split into three separate kingdoms, viz. the Median, Assyrian, and Babylonian. The first king of the Median kingdom was Arbaces; and this kingdom lasted till the time of Astyages, who was subdued and divested of his kingdom by Cyrus.

In the time of Cyrus there arose a new and second monarchy called the Persian, which stood upwards of 200 years from Cyrus, whose reign began A. M. 3468, to Darius Codomannus, who was conquered by Alexander, and the empire translated to the Greeks A. M. 3674. The first monarch wss Cyrus, founder of the empire. 2. Cambyses, the son of Cyrus. 3. Smerdis. 4. Darius, the son of Hystaspes, who reigned 521 years before Christ. 5. Xerxes, who reigned 485 years before Christ. 6. Artaxerxes Longimanus, who reigned 464 years before Christ. 7. Xerxes the second. 8. Ochus, or Darius, called Nothus, 424 years before Christ. 9. Artaxerxes Mnemon, 405 years before Christ. 10. Artaxerxes Ochus, 359 years before Christ. 11. Arses, 338 years before Christ. 12. Darius Codomannus, 336 years before Christ, who was defeated by Alexander the Great, and deprived of his kingdom and life about 331 years before Christ: the dominion of Persia after his death was translated to the Greeks.

The third monarchy was the Grecian. As Alexander, when he died, did not declare who should succeed him, there started up as many kings as there were commanders. At first they governed the provinces that were divided among them under the title of viceroys; but when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in process of time, the whole empire of Alexander produced four distinct kingdoms, viz. 1. The Macedonian; the kings of which, after Alexander, were Antipater, Cassander, Demetrius, Polliorcetes, Seleucus Nicanor, Meleager, Antigonus Doson, Philip, and Perseus, under whom the Macedonian kingdom was reduced to the form of a Roman province. 2. The Asiatic kingdom, which upon the death of Alexander fell to Antigonus, comprehending that country now called Natolia, together with some other regions beyond Mount Tarus. From this kingdom proceeded two lesser ones, viz. that of Pergamus, whose last king, Attalus, appointed the Roman people to be his heir; and Pontus, reduced by the Romans into the form of a province, when they had subdued the last king Mithridates. 3. The Syrian, of whose twenty-two kings the most celebrated were, Seleucus Nicanor, founder of the kingdom; Antiochus Deus; Antiochus the Great; Antiochus Epiphanes; and Tigranes, who was conquered by the Romans under Pompey; and Syria reduced into the form of a Roman province. 4. The Egyptian, which was formed by the Greeks in Egypt, and flourished near 240 years under 12 kings, the principal of whom were Ptolemy Lagus, its founder; Ptolemy Philadelphus, founder of the Alexandrian library; and queen Cleopatra, who was overcome by Augustus, in consequence of which Egypt was added to the dominion of the Romans.

The fourth monarchy was the Roman, which lasted 244 years, from the building of the city until the time when the royal power was abrogated. The kings of Rome were, Romulus, its founder; Numa Pompilius; Tullus Hostilius; Ancus Martius; Tarquinius Priscus; Servius Tullius; and Tarquin the Proud, who was banished, and with whom terminated the regal power.

There seems in reality no necessity to make the Medes, Persians, and Greeks succeed to the whole power of the Assyrians, to multiply the number of the monarchies. It was the same empire still; and the several changes that happened in it did not constitute different monarchies. Thus the Roman empire was successively governed by princes of different nations, yet without any new monarchy being formed thereby. Rome, therefore, may be said to have immediately succeeded Babylon in the empire of the world. See EMPIRE.

Of monarchies some are absolute and despotic, where the will of the monarch is uncontroulable: others are limited, where the prince's authority is restrained by laws, and part of the supreme power lodged in other hands, as in Britain. (See GOVERNMENT.) Some monarchies again are hereditary, where the succession devolves immediately from father to son; and others are elective, where, on the death of the monarch, his successor is appointed by election, as was formerly the case in Poland.

MONARCHY MEN (Fifth), in the ecclesiastical history of England, were a set of wrong-headed and turbulent enthusiasts who arose in the time of Cromwell, and who expected Christ's sudden appearance upon earth to establish a new kingdom; and acting in consequence of this illusion, aimed at the subversion of all human government.

MONARDA. American field-basil. In botany, a genus of the class diandria, order monogynia. Corol unequal, upper lip linear, involving the filament; seeds four. Seven species; those chiefly cultivated are,

1. M. fistulosa. Purple monarda, with capitate, purple flowers. America.

2. M. oblongata. Long-leaved monarda, with ovate leaves a little tapering at the base. A native of Canada.

3. M. didyma. Scarlet monarda, which is the species chiefly valued, and by far the most ornamental of the whole. Root perennial; stems about two feet high, smooth, acute-angled; leaves ovate, glabrous, which when bruised emit a very grateful refreshing odour; flowers in whorls, and didynamous, of a bright red colour. They appear in July, and on a moist soil will continue till the middle or end of September. It is a native of America.

All these plants may be increased by parting the roots, and some of them by slips and cutting as well as seeds.

MONARDES (Nicholas), an excellent Spanish physician of Seville, who lived in the 16th century, and deservedly acquired great reputation by his practical skill and the books which he wrote. His Spanish works have been translated into Latin by Clusius, into Italian by Annibal Brigantus, and those upon American drugs have appeared in English. He died about the year 1578.

MONAS, in zoology, a genus of the class vermes, order infusoria. Worm invisible to the naked eye, most simple, pellucid, resembling a point. Five species.

1. M. atomus. Whitish, with a variable point. Found in sea-water kept a long time; with a minute black dot, sometimes two, variable in position.

2. M. punctum. A solid opake black point. Found in fetid infusions of pears, moving in a slow wavering manner.

3. M. mica. Transparent, with an oval, moveable circle in the middle. Common in purer waters.

4. M. lens. Transparent, with sometimes a greenish margin. Found in all waters; a round pellucid dot, frequently in masses, without the least vestige of intestines.

5. M. termo. A most minute, simple gelatinous point; found in most animal and vegetable infusions: of all known animals the most minute and simple, being so extremely delicate and transparent as often to elude the most highly magnifying powers, blending, as it were, in the water in which it swims.

MONASTER, an ancient town of the kingdom of Tunis, seated near the sea, 70 miles S.E. of Tunis. Lon. 11. 6 E. Lat. 35. 50 N.

MONASTERY, a convent, or house built for the reception of religious; whether it be abbey, priory, nunnery, or the like.

MONASTERY is only properly applied to the houses of monks, mendicant friars, and nuns. The rest are more properly called religious houses.

The houses belonging to the several religious orders which obtained in England and Wales were cathedrals, colleges, abbeys, priories, preceptories, commandries, hospitals, frieries, hermitages, chantries, and free chapels. These were under the direction and management of various officers. The dissolution of houses of this kind began so early as the year 1312, when the Templars were suppressed; and in 1323 their lands, churches, advowsons, and liberties, here in England, were given, by 17 Ed. II. stat. 3. to the prior and brethren of the hospital of St. John at Jerusalem. In the years 1390, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, several others houses were dissolved, and their revenues settled on different colleges in Oxford and Cambridge. Soon after the last period, cardinal Wolsey, by licence of the king and pope, obtained a dissolution of above thirty religious houses for the founding and endowing his colleges at Oxford and Ipswich. About the same time a bull was granted by the same pope to cardinal Wolsey, to suppress monasteries, where there were not above six monks, to the value of eight thousand ducats a year, for endowing Windsor, and King's College in Cambridge; and two other bulls were granted to cardinals Wolsey and Campeius, where there were less than twelve monks, and to annex them to the greater monasteries; and another bull to the same cardinals to enquire about abbeys, to be suppressed, in order to be made cathedrals. Although nothing appears to have been done in consequence of these bulls, the motive which induced Wolsey, and many others, to suppress these houses, was the desire of promoting learning; and archbishop Cranmer engaged in it with a view of carrying on the reformation. There were other causes that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be, in their hearts, attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many cheats in images, feigned miracles, and counterfeit relics, had been discovered, which had brought the monks into disgrace; the Observant friars had opposed the king's divorce from queen Catharine; and these circumstances operated, in concurrence with the king's want of a supply, and the people's desire to save their money, to forward a motion in parliament, that in order to support the king's state, and supply his wants, all the religious houses might be conferred upon the crown, which were not able to spend above 200*l.* a year; and an act was passed for that purpose, 27 Henry VIII. c. 28. By this act about three hundred and eighty houses were dissolved, and a revenue of 30 or 32,000*l.* a year came to the crown; besides about 100,000*l.* in plate and jewels. The suppression of these houses occasioned discontent, and at length an open rebellion: when this was appeased, the king resolved to suppress all the rest of the monasteries, and appointed a new visitation; which caused the greater abbeys to be surrendered apace; and it was enacted by 31 Hen. VIII. c. 13. that all monasteries, &c. which have been surrendered since the fourth of February, in the twenty-seventh year of his majesty's reign, and which hereafter shall be surrendered, shall be vested in the king. The knights of St. John of Jerusalem were also suppressed by the 32 Henry VIII. c. 24. The suppression of these greater houses by these two acts produced a revenue to the king of above 100,000*l.* a year, besides a large sum in plate and jewels. The last act of dissolution in this king's reign was the act of 37 Hen. VIII. c. 4. for dissolving colleges, free chapels, chantries &c. which act was farther enforced by 1 Edw. VI. c. 14. By this act were suppressed ninety colleges, a hundred and ten hospitals, and two thousand three hundred and seventy-four chantries and free chaples. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be follows:

Of lesser monasteries, of which we have the valuation - - - -	374
Of greater monasteries - - -	186
Belonging to the Hospitallers - -	48
Colleges - - - - -	90
Hospitals - - - - -	110
Chantries and free chapels - -	2374
Total	3182

Besides the friars houses, and those suppressed by Wolsey, and many small houses, of which we have no particular account.

The sum total of the clear yearly revenue of the several houses at the time of their dissolution, of which we have any account, seems to be as follows:

	£.	s.	d.
Of the greater monasteries	104919	13	3¼
Of all those of the lesser monastries of which we have the valuation - -	29702	1	10½
Knights Hospitallers head house in London -	2385	12	8
We have the valuation of only 28 of their houses in the country - -	3026	9	5
Friars houses, of which we have the valuation	751	2	0¼
Total	140784	19	3

If proper allowances are made for the lesser monasteries, and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least six times as much as at present; and also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It does not appear that any computation has been made of the number of persons contained in the religious houses.

Those of the lesser monasteries dissolved by 27 Hen. VIII. were reckoned at about - - - -	10,000
If we suppose the colleges and hospitals to have contained a proportionable number, these will make about	5347
If we reckon the number in the greater monasteries, according to the proportion of their revenues, they will be about 35,000; but as probably they had larger allowances in proportion to their number than those of the lesser monasteries, if we abate upon that account 5000, they will then be - - - -	30,000
One for each chantry and free chapel - - - - -	2374
Total	47,721

But as there were probably more than one person to officiate in several of the free chapels, and there were other houses which are not included within this calculation, perhaps they may be computed in one general estimate at about 50,000. As there were pensions paid to almost all those of the greater monasteries, the king did not immediately come into the full enjoyment of their whole revenues: however, by means of what he did receive, he founded six new bishoprics, viz. those of Westminster (which was changed by queen Elizabeth into a deanry, with twelve prebends, and a school), Peterborough, Chester, Gloucester, Bristol, and Oxford. And in eight other sees he founded deanries and chapters, by converting the priors and monks into deans and prebendaries, viz. Canterbury, Winchester, Durham, Worcester, Rochester, Norwich, Ely, and Carlisle. He founded also the colleges of Christ-church in Oxford, and Trinity, Cambridge, and finished King's college there. He likewise founded professorships of divinity, law, physic, and of the Hebrew and Greek tongues, in both the said universities. He gave the house of Grey Friars, and St. Bartholomew's hospital, to the city of London; and a perpetual pension to the poor knights of Windsor, and laid out great sums in building and fortifying many ports in the channel. It is observable, upon the whole, that the dissolution of these houses was an act, not of the church, but of the state; in the period preceding the reformation, by a king and parliament of the Roman catholic communion, in all points except the king's supremacy; to which the pope himself, by his bulls and licences, had led the way. See Tanner's Notitia Monastica; and for an abstract, Burn's Eccl. Law, art. Monasteries.

MONA'STICAL. Mona'stic. *a.* (*monasticus*, Latin.) Religiously recluse; pertaining to a monk (*Brown*).

MONA'STICALLY, *ad.* Reclusely; in the manner of a monk (*Swift.*)

MONAULOS. (Greek.) A kind of single flute, of higher antiquity than even the lyre, and said by some writers to have been invented in Egypt. The Egyptians called it Photinx, or crooked flute: its shape was crooked, and something like that of a bull's horn.

MONCALLIER, a town of Piedmont, seated on the Po, five miles S.E. of Turin. Lon. 7. 48 E. Lat. 45. 2 N.

MONCALVO, a strong town of Italy, in Montferrat, seated on a mountain, 12 miles S.W. of Cassel. Lon. 7. 19 E. Lat. 45. 10 N.

MO'NDAY. *s.* (from *moon* and *day.*) The second day of the week.

MONETARIUS, or Moneyer, a name which antiquaries and medalists give to those who struck the ancient coins or moneys. Many of the old Roman and other coins have the name of the monetarius, either written at length, or at least the initial letters of it. See Medal.

MONE'TIA, in botany, a genus of the class tetrandria, order monogynia; calyx four-cleft; petals four, linear; berry two-celled, with a single seed in each. One species only; a prickly shrub of the East Indies, with spines in fours, and opposite leaves glabrous on both sides; flowers axillary and sessile.

MONEY, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight to serve as a medium in commerce. See Coin, Commerce, and Medals.

Money is usually divided into real or effective, and imaginary or money of account.

I. Real money.

History of real money. Real money includes all coins, or species of gold, silver, copper, and the like; which have course in common, and do really exist. Such are guineas, pistoles, pieces of eight, ducats, &c.

Real money, civilians observe, has three essential qualities, viz. matter, form, and weight or value.

For the matter, copper is that thought to have been first coined; afterwards silver: and lastly gold, as being the most beautiful, scarce, cleanly, divisible, and pure of all metals.

The degrees of goodness are expressed in gold by carats; and in silver by pennyweights, &c. For there are several reasons for not coining them pure and without alloy, viz. the great loss and expence in refining them, the necessity of hardening them to make them more durable, and the scarcity of gold and silver in most countries. See Alloy.

Among the ancient Britons, iron rings, or, as some say, iron plates, were used for money; among the Lacedemonians, iron bars quenched with vinegar, that they might not serve for any other use. Seneca observes, that there was anciently stamped money of leather, *corium forma publica impressum.* And the same thing was put in practice by Frederic II. at the siege of Milan;

to say nothing of an old tradition among ourselves, that in the confused times of the barons wars the like was done in England: but the Hollanders, we know, coined great quantities of paste-board in the year 1574.

As to the form of money, it has been more various than the matter. Under this are comprehended the weight, figure, impression, and value.

For the impression, the Jews, though they detested images, yet stamped on the one side of their shekel the golden pot which had the manna, and on the other Aaron's rod. The Dardans stamped two cocks fighting. The Athenians stamped their coins with an owl, or an ox; whence the proverb on bribed lawyers, *Bos in lingua*. They of Ægina, with a tortoise; whence that other saying, *Virtutem et sapientiam vincunt testudines*. Among the Romans, the monetarii sometimes impressed the images of men that had been eminent in their families on the coins: but no living man's head was ever stamped on a Roman coin till after the fall of the commonwealth. From that time they bore the emperor's head on one side. From this time the practice of stamping the prince's image on coins has obtained among all civilized nations; the Turks and other Mahometans alone excepted, who, in detestation of images, inscribe only the prince's name, with the year of the transmigration of their prophet.

As to the figure, it is either round, as in Britain; multangular or irregular, as in Spain; square, as in some parts of the Indies; or nearly globular, as in most of the rest.

After the arrival of the Romans in this island, the Britons imitated them, coining both gold and silver with the images of their kings stamped on them. When the Romans had subdued the kings of the Britons, they also suppressed their coins, and brought in their own; which were current here from the time of Claudius to that of Valentinian the younger, about the space of 500 years.

Mr. Camden observes, that the most ancient English coin he had known was that of Ethelbert king of Kent, the first christian king in the island; in whose time all money accounts begin to pass by the names of pounds, shillings, pence, and mancuses. Pence seems borrowed from the Latin *pecunia*, or rather from *pendo*, on account of its just weight, which was about threepence of our money. These were coarsely stamped with the king's image on the one side, and either the mint-master's, or the city's where it was coined, on the other. Five of these pence made their schilling, probably so called from *scilingus*, which the Romans used for the fourth part of an ounce. Forty of these schillings made their pound; and 400 of these pounds were a legacy, or a portion for a king's daughter, as appears by the last will of king Alfred. By these names they translated all sums of money in their old English testament; talents by *pundes*; Judas's thirty pieces of silver by *thirtig scillinga*; tribute-money, by *penining*: the mite by *feorthling*.

But it must be observed, they had no other real money, but pence only; the rest being imaginary moneys, i. e. names of numbers or weights. Thirty of these pence made a mancus, which some take to be the same with a mark; manca as appears by an old MS. was *quinta pars unciæ*. These mancas or mancuses were reckoned both in gold and silver. For in the year 680 we read that Ina king of the West Saxons obliged the Kentish men to buy their peace at the price of 30,000 mancas of gold. In the notes on king Canute's laws, we find this distinction, that *mancusa* was as much as a mark of silver; and *manca* a square piece of gold, valued at 30 pence.

The Danes introduced a way of reckoning money by ores, *per oras*, mentioned in Domesday-book; but whether they were a several coin, or a certain sum, does not plainly appear. This, however, may be gathered from the Abbey-book of Burton, that 20 ores were equivalent to two marks. They had also a gold coin called *byzantine* or *bezant*, as being coined at Constantinople, then called *Byzantium*. The value of which coin is not only now lost, but was so entirely forgot even in the time of king Edward III. that whereas the bishop of Norwich was fined a byzantine of gold to be paid the abbot of St. Edmund's Bury for infringing his liberties (as it had been enacted by parliament in the time of the Conqueror), no man then living could tell how much it was: so it was referred to the king to rate how much he should pay. Which is the more unaccountable, because but 100 years before, 200,000 bezants were exacted by the soldan for the ransom of St. Louis of France; which were then valued at 100,000 livres.

Though the coining of money be a special prerogative of the king, yet the ancient Saxon princes communicated it to their subjects, insomuch that in every good town there was at least one mint; but at London eight; at Canterbury four for the king, two for the archbishop, one for the abbot at Winchester, six at Rochester; at Hastings two, &c.

The Norman kings continued the same custom of coining only pence, with the prince's image on one side, and on the other the name of the city where it was coined, with a cross so deeply impressed, that it might be easily parted and broke into two halves, which, so broken, they called halfpence; or into four parts, which they called fourthings or farthings.

In the time of king Richard I. money coined in the east parts of Germany came in special request in England on account of its purity, and was called easterling money, as all the inhabitants of those parts were called Easterlings. And shortly after, some of those people skilled in coining were sent for hither, to bring the coin to perfection; which since has been called sterling for Easterling. See Sterling.

King Edward I. who first adjusted the measure of an ell by the length of his arm, herein imitating Charles the Great, was the first also who established a certain standard for the coin, which is expressed to this effect by Greg. Rockley, mayor of London, and mint-master.—" A pound of money containeth twelve ounces: in a pound there ought to be eleven ounces, two easterlings, and one farthing; the rest alloy. The said pound ought to weigh twenty shillings and three-pence in account and weight. The ounce ought to weigh twenty pence, and a penny twenty-four grains and a half. Note, that eleven ounces two-pence sterling ought to be of pure silver, called leaf-silver; and the minter must add of other weight seventeen-pence halfpenny farthing, if the silver be so pure."

About the year 1320 the states of Europe first began to coin gold; and among the rest our king Edward III. The first pieces he coined were called florences, as being coined by Florentines; afterwards he coined nobles; then rose-nobles, current at 6s. and 8d. half-nobles called half-pennies, at 5s. and 4d. of gold; and quarters at 20d. called farthings of gold.—The succeeding kings coined rose-nobles, and double rose-nobles, great sovereigns, and half Henry nobles, angels, and shillings.

King James I. coined unites, double crowns, Britain crowns; then crowns, half-crowns, &c.

2. *Comparative value of money and commodities at different periods.*—The English money, though the same names do by no means correspond with the same quantity of precious metal as formerly, has not changed so much as the money of most other countries. From the time of William the Conqueror, the proportion between the pound, the shilling, and the penny, seems to have been uniformly the same as at present.

Edward III. as already mentioned, was the first of our kings that coined any gold; and no copper was coined by authority before James I. These pieces were not called farthings, but farthing tokens, and all people were at liberty to take or refuse them. Before the time of Edward III. gold was exchanged, like any other commodity, by its weight; and before the time of James I. copper was stamped by any one person who chose to do it.

In the year 712 and 727, an ewe and lamb were rated at 1s. Saxon money till a fortnight after Easter. Between the years 900 and 1000, two hides of land, each containing about 120 acres, were sold for 100 shillings. In 1000, by king Ethelred's laws, a horse was rated at 30s. a mare, or a colt of a year old, at 20s. a mule, or young ass, at 12s. an ox at 30s. a cow at 24s. a swine at 8d. sheep at 1s. In 1043, a quarter of wheat was sold for 60d. Hence it is computed, that in the Saxon times there was ten times less money, in proportion to commodities, than at present. Their nominal specie, therefore, being about three times higher than ours, the price of every thing, according to our present language, must be reckoned thirty times cheaper than it is now.

In the reign of William the Conqueror, commodities were ten times cheaper than they are at present; from which we cannot help forming a very high idea of the wealth and power of that king: for his revenue was 400,000l. per annum, every pound being equal to that weight of silver, consequently the whole may be estimated at 1,200,000l. of the present computation; a sum which, considering the different value of money between that period and the present, was equivalent to 12,000,000l. of modern estimation.

The most necessary commodities do not seem to have advanced their price from William the Conqueror to Richard I.

The price of corn in the reign of Henry III. was near half the mean price in our times. Bishop Fleetwood has shown, that in the year 1240, which was in this reign, 4l. 13s. 9d. was worth about 50l. of our present money. About the latter end of this reign, Robert de Hay, rector of Souldern, agreed to receive 100s. to purchase to himself and successor the annual rent of 5s. in full compensation of an acre of corn.

Butcher's meat, in the time of the great scarcity in the reign of Edward II. was, by a parliamentary ordinance, sold three times cheaper than our mean price at present; poultry somewhat lower, because, being now considered as a delicacy, it has risen beyond its proportion. The mean price of corn at this period was half the present value, and the mean price of cattle one-eighth.

In the next reign, which was that of Edward III. the most necessary commodities were in general about three or four times cheaper than they are at present.

In these times, knights who served on horseback in the army had 2s. a day, and a foot archer 6d. which last would now be equal to a crown a day. This pay has continued nearly the same nominally (only that in the time of the commonwealth the pay of the horse was advanced to 2s. 6d. and that of the foot 1s. though it was reduced again at the Restoration), but soldiers were proportionably of a better rank formerly.

In the time of Henry VI. corn was about half its present value, other commodities much cheaper. Bishop Fleetwood has determined, from a most accurate consideration of every circumstance, that 3l. in this reign was equivalent to 28l. or 30l. now.

In the time of Henry VII. many commodities were three times as cheap here, and in all Europe, as they are at present, there having been a great increase of gold and silver in Europe since his time, occasioned by the discovery of America.

The commodities whose price has risen the most since before the time of Henry VII. are butchers' meat, fowls, and fish, especially the latter. And the reason why corn was always much dearer in proportion to other eatables, according to their prices at present, is, that in early times agriculture was little understood. It required more labour and expence, and was more precarious than it is at present. Indeed, notwithstanding the high price of corn in the times we are speaking of, the raising of it so little answered the expence, that agriculture was almost universally quitted for grazing; which was more profitable, notwithstanding the low price of butchers' meat. So that there was constant occasion for statutes to restrain grazing, and to propagate agriculture; and no effectual remedy was found till the bounty upon the exportation of corn; since which, above ten times more corn has been raised in this country than before.

The price of corn in the time of James I. and consequently that of other necessaries of life, was not lower, but rather higher, than at present: wool is not two-thirds of the value it was then; the finer manufactures having sunk in price by the progress of art and industry, notwithstanding the increase of money. Butchers' meat was higher than at present. Prince Henry made an allowance of near 4d. per pound for all the beef and mutton used in his family. This may be true with respect to London; but the price of butchers' meat in the country, which does not even now much exceed this price at a medium, has certainly greatly increased of late years, and particularly in the northern counties.

The prices of commodities are higher in England than in France; besides that the poor people of France live upon much less than the poor in England, and their armies are maintained at less expence. It is computed by Mr. Hume, that a British army of 20,000 men is maintained at near as great an expence as 60,000 in France, and that the English fleet, in the war of 1741, required as much money to support it as all the Roman legions in the time of the emperors. However, all that we can conclude from this is, that money is much more plentiful in Europe at present than it was in the Roman empire.

In the 13th century the common interest which the Jews had for their money, Voltaire says, was 20 per cent. But with regard to this, we must consider the great contempt that nation was always held in, the large contributions they were frequently obliged to pay, the risk they ran for never receiving the principal, the frequent confiscations of all their effects, and the violent persecutions to which they were exposed; in which circumstances it was impossible for them to lend money at all, unless for most extravagant interest, and much disproportioned to its real value. Before the discovery of America, and the plantation of our colonies, the interest of money was generally 12 per cent. all over Europe; and it has been growing gradually less since that time, till it is now generally about four or five.

When sums of money are said to be raised by a whole people, in order to form a just estimate of it we must take into consideration not only the quantity of the precious metal according to the standard of the coin, and the proportion of the quantity of coin to the commodities, but also the number and riches of the people who raise it: for populous and rich countries will much more easily raise any certain sum of money than one that is thinly inhabited, and chiefly by poor people. This circumstance greatly adds to our surprise at the vast sums of money raised by William the Conqueror, who had a revenue nearly in value equal to 12,000,000l. of our money (allowance being made for the standard of coin and the proportion it bore to commodities), from a country not near so populous or rich as England is at present. Indeed, the accounts historians give us of the revenues of this prince, and the treasure he left behind him, are barely credible.

II. IMAGINARY MONEY, or *Money of account*, is that which has never existed, or at least which does not exist in real specie, but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed, like current coins, which the authority of the sovereign raises or lowers according to the exigences of the state. Of which kind are pounds, livres, marks, maravedies, &c.

Money of account among the ancients.—1. The Grecians reckoned their sums of money by *drachma*, *minæ*, and *talenta*. The drachma was equal to 7¾d. sterling; 100 drachmæ made the mina, equal to 3l. 4s. 7d. sterling; 60 minæ made the talent, equal to 193l. 15s. sterling: hence 100 talents amounted to 19,375l. sterling. The mina and talentum, indeed, were different in different provinces: their proportions in Attic drachms are as follow. The Syrian mina contained 25 Attic drachms; the Ptolemaic 33⅓; the Antiochic and Eubæan 100; the Babylonic 116; the greater Attic and Tyrian 133⅓; the Æginean and Rhodian 166⅔. The Syrian talent contained 15 Attic minæ; the Ptolemaic 20; the Antiochic 60: the Eubæan 60; the Babylonic 70; the greater Attic and Tyrian 80; the Æginean and Rhodian 100.

2. Roman moneys of account were the *sestertius* and *scstertium*. The sestertius was equal to 1d. 3¾q. sterling. One thousand of these made the sesterium equal to 8l. 1s. 5d. 2q. sterling. One thousand of these sestertia made the decies sestertium (the adverb *centies* being always understood) equal to 8072l. 18s. 4d. sterling. The decies sestertium they also called *decies centena millia nummum.* Centies sestertium, or centies HS, were equal to 80,729l. 3s. 4d. Millies HS to 807,291l. 13s. 4d. Millies centies HS to 888,020l. 1s. 8d.

THEORY OF MONEY.

1. *Of artificial or material money.*

I. As far back as our accounts of the transactions of mankind reach, we find they had adopted the precious metals, that is, silver and gold, as the common measure of value, and as the adequate equivalent for every thing alienable.

The metals are admirably adapted for this purpose: they are perfectly homogeneous: when pure, their masses, or bulks, are exactly in proportion to their weights: no physical difference can be found between two pounds of gold or silver, let them be the production of the mines of Europe, Asia, Africa, or America: they are perfectly malleable, fusible, and suffer the most exact division which human art is able to give them: they are capable of being mixed with one another, as well as with metals of a baser, that is, of a less homogeneous nature, such as copper: by this mixture they spread themselves uniformly through the whole mass of the composed lump, so that every atom of it becomes proportionally possessed of a share of this noble mixture; by which means the sub-division of the precious metals is rendered very extensive.

Their physical qualities are invariable: they lose nothing by keeping; they are solid and durable; and though their parts are separated by friction, like every other thing, yet still they are of the number of those which suffer least by it.

If money, therefore, can be made of any thing, that is, if the proportional value of things vendible can be measured by any thing material, it may be measured by the metals.

II. The two metals being pitched upon as the most proper substances for realising the ideal scale of money, those who undertake the operation of adjusting a standard must constantly keep in their eye the nature and qualities of a scale, as well as the principles upon which it is formed.

The unit of the scale must constantly be the same, although realised in the metals, or the whole operation fails in the most essential part. This realising the unit is like adjusting a pair of compasses to a geometrical scale, where the smallest deviation from the exact opening once given must occasion an incorrect measure. The metals, therefore, are to money what a pair of compasses is to a geometrical scale.

This operation of adjusting the metals to the money of account implies an exact and determinate proportion of both metals to the money-unit, realised in all the species and denominations of coin, adjusted to that standard.

The smallest particle of either metal added to, or taken away from, any coins, which represent certain determinate parts of the scale, overturns the whole system of material money. And if, notwithstanding such variation, these coins continue to bear the same denominations as before, this will as effectually destroy their usefulness in measuring the value of things, as it would overturn the usefulness of a pair of compasses to suffer the opening to vary, after it is adjusted to the scale representing feet, toises, miles or leagues, by which the distances upon the plan are to be measured.

III. Debasing the standard is a good term; because it conveys a clear and distinct idea. It is diminishing the weight of the pure metal contained in that denomination by which a nation reckons, and which we have called the money-unit. Raising the standard requires no farther definition, being the direct contrary.

IV. Altering the standard (that is, raising or debasing the value of the money-unit) is like altering the national measures or weights. This is best discovered by comparing the thing altered with things of the same nature which have suffered no alteration. Thus, if the foot of measure was altered at once over all England, by adding to it, or taking from it any proportional part of its standard length, the alteration would be best discovered by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound sterling, which is the English unit, shall be found any how changed, and if the variation it has met with be difficult to ascertain because of a complication of circumstances, the best way to discover it will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

V. Artists pretend, that the precious metals, when absolutely pure from any mixture, are not of sufficient hardness to constitute a solid and lasting coin. They are found also in the mines mixed with other metals of a baser nature; and the bringing them to a state of perfect purity occasions an unnecessary expence. To avoid, therefore, the inconvenience of employing them in all their purity, people have adopted the expedient of mixing them with a determinate proportion of other metals, which hurts neither their fusibility, malleability, beauty, or lustre. This metal is called alloy; and, being considered only as a support to the principal metal, is accounted of no value in itself. So that eleven ounces of gold, when mixed with one ounce of silver, acquires by that addition no augmentation of value whatever.

This being the case, we shall, as much as possible, overlook the existence of alloy, in speaking of money, in order to render language less subject to ambiguity.

2. *Incapacities of the metals to perform the office of an invariable measure of value.*

I. Were there but one species of such a substance as we have represented gold and silver to be; were there but one metal possessing the qualities of purity, divisibility, and durability; the inconveniences in the use of it for money would be fewer by far than they are found to be as matters stand.

Such a metal might then, by an unlimited division into parts exactly equal, be made to serve as a tolerably steady and universal measure. But the rivalship between the metals, and the perfect equality which is found between all their physical qualities, so far as regards purity and divisibility, render them so equally well adapted to serve as the common measure of value, that they are universally admitted to pass current as money.

What is the consequence of this? That the one measures the value of the other, as well as that of every other thing. Now the moment any measure begins to be measured by another, whose proportion to it is not physically, perpetually, and invariably the same, all the usefulness of such a measure is lost. An example will make this plain.

A foot of measure is a determinate length. An English foot may be compared with the Paris foot, or with that of the Rhine; that is to say, it may be measured by them: and the proportion between their lengths may be expressed in numbers; which proportion will be the same perpetually. The measuring the one by the other will occasion no uncertainty; and we may speak of length by Paris feet, and be perfectly well understood by others who are used to measure by the English foot, or by the foot of the Rhine.

But suppose that a youth of twelve years old takes it into his head to measure from time to time, as he advances in age, by the length of his own foot, and that he divides this growing foot into inches and decimals, what can be learned from his account of measures? As he increases in years, his foot, inches, and subdivisions, will be gradually lengthening; and were every man to follow his example, and measure by his own foot, then the foot of a measure now established would totally cease to be of any utility.

This is just the case with the two metals. There is no determinate invariable proportion between their value; and the consequence of this is, that when they are both taken for measuring the value of other things, the things to be measured, like lengths to be measured by the young man's foot, without changing their relative proportion between themselves, change, however, with respect to the denominations of both their measures. An example will make this plain.

Let us suppose an ox to be worth 3000 pounds weight of wheat, and the one and the other to be worth an ounce of gold, and an ounce of gold to be worth exactly 15 ounces of silver: if the case should happen, that the proportional value between gold and silver should come to be as 14 is to 1, would not the ox, and consequently the wheat, be estimated at less in silver, and more in gold, than formerly? Farther, would it be in the power of any state to prevent this variation in the measure of the value of oxen and wheat, without putting into the unit of their money less silver and more gold than formerly?

If therefore any particular state should fix the standard of the unit of their money to one species of the metals, while in fact both the one and the other are actually employed in measuring value; does not such a state resemble the young man who measures all by his growing foot? For if silver, for example, be retained as the standard, while it is gaining upon gold one fifteenth additional value; and if gold continue all the while to determine the value of things as well as silver; it is plain, that, to all intents and purposes, this silver-measure is lengthening daily like the young man's foot, since the same weight of it must become every day equivalent to more and more of the same commodity; notwithstanding that we suppose the same proportion to subsist, without the least variation, between that commodity and every other species of things alienable.

Buying and selling are purely conventional, and no man is obliged to give his merchandise at what may be supposed to be the proportion of its worth. The use, therefore, of an universal measure, is to mark, not only the relative value of the things to which it is applied as a measure, but to discover in an instant the proportion between the value of those, and of every other commodity valued by a determinate measure in all the countries of the world.

Were pounds sterling, livres, florins, piastres, &c. which are all money of account, invariable in their values, what a facility would it produce in all conversions, what an assistance to trade! But as they are all limited or fixed to coins, and consequently vary from time to time, this example shows the utility of the invariable measure which we have described.

There is another circumstance which incapacitates the metals from performing the office of money: the substance of which the coin is made is a commodity which rises and sinks in its value with respect to other commodities, according to the wants, competition, and caprices of mankind. The advantage, therefore, found in putting an intrinsic value into that substance which performs the function of money of account, is compensated by the instability of that intrinsic value; and the advantage obtained by the stability of paper, or symbolical money, is compensated by the defect it commonly has of not being at all times susceptible of realization into solid property or intrinsic value.

In order, therefore, to render material money more perfect, this quality of metal, that is, of a commodity, should be taken from it; and in order to render paper-money more perfect, it ought to be made to circulate upon metallic or land security.

II. There are several smaller inconveniences accompanying the use of the metals, which we shall here shortly enumerate.

1*mo*, No money made of gold or silver can circulate long without losing its weight, although it all along preserves the same denomination. This represents the contracting a pair of compasses which had been rightly adjusted to the scale.

2*do*, Another inconvenience proceeds from the fabrication of money. Supposing the faith of princes who coin money to be inviolable, and the probity as well as the capacity of those to whom they commit the inspection of the business of the metals to be sufficient, it is hardly possible for workmen to render every piece exactly of a proper weight, or to preserve the due proportion between pieces of different denominations; that is to say, to make every ten sixpences exactly of the same weight with every crown-piece and every five shillings struck in a coinage. In proportion to such inaccuracies the parts of the scale become unequal.

3*tio*, Another inconvenience, and far from being inconsiderable, flows from the expence requisite for the coining of money. This expence adds to its value as a manufacture, without adding any thing to its weight.

4*to*, The last inconvenience is, that by fixing the money of account entirely to the coin, without having any independent common measure, (to mark and controul these deviations from mathematical exactness, which are either inseparable from the metals themselves, or from the fabrication of them,) the whole measure of value, and all the relative interests of debtors and creditors, become at the disposal not only of workmen in the mint, of Jews who deal in money, of clippers and washers of coin; but they are also entirely at the mercy of princes, who have the right of coinage, and who have frequently also the right of raising or debasing the standard of the coin, according as they find it most for their present and temporary interest.

3. *Methods which may be proposed for lessening the several inconveniences to which material money is liable.*

The inconveniences from the variation in the relative value of the metals to one another may in some measure be obviated by the following expedients.

1*mo*, By considering one only as the standard, and leaving the other to seek its own value like any other commodity.

2*do*, By considering one only as the standard, and fixing the value of the other from time to time by authority, according as the market-price of the metals shall vary.

3*tio*, By fixing the standard of the unit according to the mean proportion of the metals, attaching it to neither; regulating the coin accordingly; and upon every considerable variation in the proportion between them, either to make a new coinage, or to raise the denomination of one of the species, and lower it in the other, in order to preserve the unit exactly in the mean proportion between the gold and silver.

4*to*, To have two units and two standards, one of gold and one of silver, and to allow every body to stipulate in either.

5*to*, Or last of all, to oblige all debtors to pay one half in gold, and one half in the silver standard.

4. *Variations to which the value of the money-unit is exposed from every disorder in the coin.*

Let us suppose, at present, the only disorder to consist in a want of the due proportion between the gold and silver in the coin.

This proportion can only be established by the market-price of the metals; because an augmentation and rise in the demand for gold or silver has the effect of augmenting the value of the metal demanded. Let us suppose, that to-day one pound of gold may buy fifteen pounds of silver; if to-morrow there be a high demand for silver, a competition among merchants to have silver for gold will ensue: they will contend who shall get the silver at the rate of 15 pounds for one of gold: this will raise the price of it; and in proportion to their views of profit, some will accept of less than the 15 pounds. This is plainly a rise in the silver, more properly than a fall in the gold; because it is the competition for the silver which has occasioned the variation in the former proportion between the metals.

Let us now suppose that a state, having with great exactness examined the proportion of the metals in the market, and having determined the precise quantity of each for realising or representing the money-unit, shall execute a most exact coinage of gold and silver coin. As long as that proportion continues unvaried in the market, no inconvenience can result from that quarter in making use of metals for money of account.

But let us suppose the proportion to change; that the silver, for example, shall rise in its value with regard to gold: will it not follow, from that moment, that the unit realized in the silver will become of more value than the unit realized in the gold coin?

But as the law has ordered them to pass as equivalents for one another, and as debtors have always the option of paying in what legal coin they think fit, will they not all choose to pay in gold? and will not then the silver coin be melted down or exported, in order to be sold as bullion, above the value it bears when it circulates in coin? Will not this paying in gold also really diminish the value of the money-unit? since upon this variation every thing must sell for more gold than before, as we have really observed.

Consequently, merchandise, which have not varied in their relative value to any other thing but to gold and silver, must be measured by the mean proportion of the metals; and the application of any other measure to them is altering the standard. If they are measured by gold, the standard is debased; if by silver, it is raised.

If, to prevent the inconvenience of melting down the silver, the state shall give up affixing the value of their unit to both species at once, and shall fix it to one, leaving the other to seek its price as any other commodity; in that case, no doubt, the melting down of the coin will be prevented; but will this ever restore the value of the money-unit to its former standard? Would it, for example, in the foregoing supposition, raise the debased value of the money-unit in the gold coin, if that species were declared to be the standard? It would indeed render silver coin purely a merchandise, and, by allowing it to seek its value, would certainly prevent it from being melted down as before; because the pieces would rise conventionally in their denomination; or an agio, as it is called, would be taken in payments made in silver: but the gold would not, on that account, rise in its value, or begin to purchase any more merchandise than before. Were therefore the standard fixed to the gold, would not this be an arbitrary and a violent revolution in the value of the money-unit, and a debasement of the standard?

If, on the other hand, the state should fix the standard to the silver, which we suppose to have risen in its value, would that ever sink the advanced value which the silver coin had gained above the worth of the former standard unit? and would not this be a violent and an arbitrary revolution in the value of the money-unit, and a raising of the standard?

The only expedient, therefore, is, in such a case, to fix the numerary unit to neither of the metals, but to contrive a way to make it fluctuate in a mean proportion between them; which is in effect the introduction of a pure ideal money of account.

The regulation of fixing the unit by the mean proportion, ought to take place at the instant the standard unit is fixed with exactness both to the gold and silver. If it be introduced long after the market proportion between the metals has deviated from the proportion established in the coin; and if the new regulation is made to have a retrospect, with regard to the acquitting of permanent contracts entered into while the value of the money-unit had attached itself to the lowest currency in consequence of the principle above laid down; then the restoring the money-unit to that standard where it ought to have remained (to wit, to the mean proportion) is an injury to all debtors who have contracted since the time that the proportion of the metals began to vary.

This is clear from the former reasoning. The moment the market price of the metals differs from that in the coin, every one who has payments to make pays in that species which is the highest rated in the coin; consequently, he who lends, lends in that species. If after the contract, therefore, the unit is carried up to the mean proportion, this must be a loss to him who had borrowed.

From this we may perceive, why there is less inconvenience from the varying of the proportion of the metals, where the standard is fixed to one of them, than when it is fixed to both. In the first case, it is at least uncertain whether the standard or the merchandise species is to rise; consequently it is uncertain whether the debtors or the creditors are to gain by a variation. If the standard species should rise, the creditors will gain; if the merchandise species rises, the debtors will gain; but when the unit is attached to both species, then the creditors never can gain, let the metals vary as they will: if silver rises, then debtors will pay in gold; if gold rises, the debtors will pay in silver. But whether the unit be attached to one or to both species, the infallible consequence of a variation is, that one half of the difference is either gained or lost by debtors and creditors. The invariable unit is constantly the mean proportional between the two measures.

5. *How the variations of the intrinsic value of the unit of money must affect all the domestic interest of a nation.*

If the changing the content of the bushel by which grain is measured would affect the interest of those who are obliged to pay, or who are entitled to receive, a certain number of bushels of grain for the rent of lands; in the same manner must every variation in the value of the unit of account affect all persons who, in permanent contracts, are obliged to make payments, or who are obliged to received sums of money stipulated in multiples or in fractions of that money-unit.

Every variation, therefore, upon the intrinsic value of the money-unit has the effect of benefiting the class of creditors at the expence of debtors, or *vice versa*.

This consequence is deduced from an obvious principle. Money is more or less valuable in proportion as it can purchase more or less of every kind of merchandise. Now, without entering anew into the causes of the rise and fall of prices, it is agreed upon all hands, that whether an augmentation of the general mass of money in circulation has the effect of raising prices in general, or not, any augmentation of the quantity of the metals appointed to be put into the money-unit must at least affect the value of that money-unit, and make it purchase more of any commodity than before: that is to say, 113 grains of fine gold, the present weight of a pound sterling in gold, can buy 113 pounds of flour; were the pound sterling raised to 114 grains of the same metal, it would buy 114 pounds of flour: consequently, were the pound sterling augmented by one grain of gold, every miller who paid a rent of ten pounds a year would be obliged to sell 1140 pounds of his flour, in order to procure ten pounds to pay his rent, in place of 1130 pounds of flour, which he sold formerly to procure the same sum: consequently, by this innovation, the miller must lose yearly ten pounds of flour, which his master consequently must gain. From this example it is plain, that every augmentation of metals put into the pound sterling, either of silver or gold, must imply an advantage to the whole class of creditors who are paid in pounds sterling, and consequently must be a proportional loss to all debtors who must pay by the same denomination.

6. *Regulations which the principle of this inquiry point out as expedient to be made by a new statute for regulating the British coin.*

Let us now examine what regulations it may be proper to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value of the pound sterling realized in gold and in silver, in spite of all the incapacities inherent in the metals to perform the functions of an invariable scale or measure of value.

1. The first point is to determine the exact number of grains of fine gold and fine silver which are to compose it, according to the then proportion of the metals in the London market.

2. To determine the proportion of these metals with the pound troy; and in regard that the standard of gold and silver is different, let the mint price of both metals be regulated according to the pound troy fine.

3. To fix the mint price within certain limits; that is to say, to leave to the king and council, by proclamation, to carry the mint price of bullion up to the value of the coin, as is the present regulation, or to sink it to per cent. below that price, according as government shall incline to impose a duty upon coinage.

4. To order, that silver and gold coin shall be struck of such denominations as the king shall think fit to appoint; in which the proportion of the metals above determined shall be constantly observed through every denomination of the coin, until necessity shall make a new general coinage unavoidable.

5. To have the number of grains of the fine metal in every piece marked upon the exergue, or upon the legend of the coin, in place of some initial letters of titles, which not one person in a thousand can decypher; and to make the coin of as compact a form as possible, diminishing the surface of it as much as is consistent with beauty.

6. That it shall be lawful for all contracting parties to stipulate their payments either in gold or silver coin, or to leave the option of the species to one of the parties.

7. That where no particular stipulation is made, creditors shall have power to demand payment, half in one species, half in the other; and when the sum cannot fall equally into gold and silver coins, the fractions to be paid in silver.

8. That in buying and selling, when no particular species has been stipulated, and when no act in writing has intervened, the option of the species shall be competent to the buyer.

9. That all sums paid or received by the king's receivers, or by bankers, shall be delivered by weight, if demanded.

10. That all money which shall be found under the legal weight, from whatever cause it may proceed, may be rejected in every payment whatsoever: or if offered in payment of a debt above a certain sum, may be taken according to its weight, at the then mint price, in the option of the creditor.

11. That no penalty shall be incurred by those who melt down or export the nation's coin; but that washing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the variation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the market-price of the metals, the price of both shall be changed according to the following rule:

Let the price of the pound troy fine gold in the coin be called G.

Let the price of ditto in the silver be called S.

Let the new proportion between the market-price of the metal be called P.

Then state this formula:

$$\frac{G}{2P} + \frac{S}{2} = \text{to a pound troy fine silver in sterling currency.}$$

$$\frac{S}{2} + P + \frac{G}{2} = \text{to a pound troy fine gold in sterling currency.}$$

This will be a rule for the mint to keep the price of the metals constantly at par with the price of the market; and coinage may be imposed, as has been described, by fixing the mint price of them at a certain rate below the value of the fine metals in the coin.

13. As long as the variation of the market-price of the metals shall not carry the price of the rising metal so high as the advanced price of the coin above the bullion, no alteration need be made on the denomination of either species.

14. So soon as the variation of the market price of the metals shall give a value to the rising species, above the difference between the coin and the bullion; then the king shall alter the denominations of all the coin, silver and gold, adding to the coins of the rising metal exactly what is taken from those of the other. An example will make this plain:

Let us suppose that the coinage has been made according to the proportion of 14.5 to 1; that 20 shillings, or 4 crown-pieces, shall contain, in fine silver, 14.5 times as many grains as the guinea, or the gold pound, shall contain grains of fine gold. Let the new proportion of the metals be supposed to be 14 to 1. In that case, the 20 shillings, or the 4 crowns, will contain $\frac{11}{26}$ more value than the guinea. Now, since there is no question of making a new general coinage upon every variation, in order to adjust the proportion of the metals in the weight of the coins, that proportion might be adjusted by changing their respective denominations according to this formula:

Let the 20 shillings, or 4 crowns, in coin, be called S. Let the guinea be called G. Let the difference between the old proportion and the new, which is $\frac{1}{29}$, be called P. Then say, $S + \frac{P}{2}$ = a pound sterling, and $G + \frac{P}{2}$ = a pound sterling.

By this it appears that all the silver coin must be raised in its denomination $\frac{1}{58}$, and all the gold coin must be lowered in its denomination $\frac{1}{58}$; yet still $S + G$ will be equal to two pounds sterling, as before, whether they be considered according to the old or according to the new denominations.

But it may be observed, that the imposition of coinage rendering the value of the coin greater than the value of the bullion, that circumstance gives a certain latitude in fixing the new denominations of the coin, so as to avoid minute fractions. For, providing the deviation from the exact proportion shall fall within the advanced price of the coin, no advantage can be taken by melting down one species preferably to another; since, in either case, the loss incurred by melting the coin must be greater than the profit made upon selling the bullion. The mint price of the metals, however, may be fixed exactly, that is, within the value of a farthing upon a pound of fine silver or gold. This is easily reckoned at the mint; although upon every piece in common circulation the fractions of farthings would be inconvenient.

15. That notwithstanding the temporary variations made upon the denomination of the gold and silver coins, all contracts formerly entered into, and all stipulations in pounds, shillings, and pence, may continue to be acquitted according to the old denominations of the coins, paying one-half in gold and one-half in silver: unless in the case where a particular species has been stipulated; in which case the sum must be paid according to the new regulation made upon the denomination of that species, to the end that neither profit nor loss may result to any of the parties.

16. That notwithstanding the alterations on the mint price of the metals, and in the denomination of the coins, no change shall be made upon the weight of the particular pieces of the latter, except in the case of a general re-coinage of one denomination at least: that is to say, the mint must not coin new guineas, crowns, &c. of a different weight from those already in currency, although by so doing the fractions might be avoided. This would occasion confusion, and the remedy would cease to be of any use upon a new change in the proportion of the metals. But it may be found convenient for removing the small fractions in shillings and sixpences, to recoin such denominations altogether, and to put them to their integer numbers, of twelve and of sixpence, without changing in any respect their proportion of value to all other denominations of the coin: this will be no great expence, when the bulk of the silver coin is put into 5 shilling pieces.

By this method of changing the denominations of the coin, there never can result any alteration in the value of the pound sterling; and although fractions of value may now and then be introduced, in order to prevent the abuses to which the coin would otherwise be exposed by the artifice of those who melt it down, yet still the inconvenience of such fractions may be avoided in paying, according to the old denominations, in both species, by equal parts. This will also prove that no change is thereby made in the true value of the national unit of money.

17. That it be ordered, that shillings and sixpences shall only be current for twenty years; and all other coins, both gold and silver, for forty years or more. For ascertaining which term there may be marked upon the exergue of the coin the last year of their currency, in place of the date of their fabrication. This term elapsed, or the date effaced, that they shall have no more currency whatsoever; and, when offered in payment, may be received as bullion at the actual price of the mint, or refused, at the option of the creditor.

18. That no foreign coin shall have any legal currency, except as bullion at the mint price.

By these and the like regulations may be prevented, 1mo, The melting or exporting of the coin in general. 2do, The melting or exporting one species, in order to sell it as bullion at an advanced price. 3tio, The profit in acquitting obligations preferably in one species to another. 4to, The degradation of the standard, by the wearing of the coin, or by a change in the proportion between the metals. 5to, The circulation of the coin below the legal weight. 6to, The profit that other nations reap by paying their debts more cheaply to Great Britain than Great Britain can pay hers to them.

And the great advantage of it is, that it is an uniform plan, and may serve as a perpetual regulation, compatible with all kinds of denominations of coins, variations in the proportion of the metals, and with the imposition of a duty upon coinage, or with the preserving it free; and further, that it may in time be adopted by other nations, who will find the advantage of having their money of account preserved perpetually at the same value, with respect to the denominations of all foreign money of account established on the same principles.

A TABLE, exhibiting the standard weight, value, and a comparative view of English Gold Money from King William I. Ann. 1066, to King George III. Ann. 1764.

Years of the kings and queens reigns, or the dates of the several mint indentures.		Standard of the gold at each period.		Value or No of pounds, &c. the lb. Troy of stand. gold has been coined into.	Value or number of pounds, &c. the oz. Troy has been coined into.	Value of 20 shillings of coined gold at each period in our present money.	Proportion of the same 20 shillings to our present 20 shillings.	Proportion between the current value of the lb. Troy. of standard silver and standard gold.	Proportion of fine silver to fine gold at each period.

Before we terminate this article, we add the following brief account of the coins, or current moneys, of different countries.

In Ireland the coins are as in England, viz. guineas, shillings, &c. with this difference, that the English shilling passes for twenty-six halfpence, which are the only coin peculiar to that country.

Coins of the French Empire.

The current coins of France were formerly the double louis (gold), the louis (gold), the piece of six livres (silver), that of three livres, the ecu (silver), twenty-four sols piece (silver), the twelve (silver), the six sols piece (silver), the large or double sol (of copper), the sol (of copper), and the half and quarter sol, or pieces of two and one liard. There are also ancient pieces made of copper and silver, denominated pieces of six liards, value one sol and a half.

According to the new system, an attempt has been made, with partial success, to introduce the following currency. The denomination of livre has been changed into that of franc, with an alteration, in the small proportion of only threepence to the louis. The franc is then assumed as the basis or unit of all their computations; and all values are reckoned upwards by tens, hundreds, and thousands of francs, and downwards by tenth parts and hundredth parts of francs.

Some coins have been put into circulation agreeably to this new system, viz. in silver pieces of 5 francs, in pieces of 30 sols, being a fourth of the franc, and in pieces of 15 sols, being the eighth of the franc; in copper pieces of 5 centimes (five hundredths) equal to the old sol, and of 10 centimes (ten hundredths) or 1 decime, equal to the double sol.

Value of the coinage of both nation.—As a primary principle, the traveller must recollect, that whenever the course of exchange between the two countries is at par, the French louis is to be considered as of equal value to the English pound sterling.

Existing English coins.		*French value.*
The guinea	is equal to	One louis and one 24 sols piece.
The crown piece	—	The six livre piece.
The half-crown	—	The three livre piece.
The shilling	—	The 24 sols piece.
The sixpence	—	The 12 sols piece.
The penny	—	The double sol.
The halfpenny	—	The sol.
The farthing	—	The deux liards.

Existing French coins.		*English value.*
The louis, containing 24 livres or francs		One pound sterling.
The six livre piece	—	Five shillings.
The five franc piece	—	Four shillings and twopence.
The livre piece	—	Half-crown.
The 30 sol piece	—	Fifteen pence.
The 24 sol piece	—	One shilling.
The 15 sol piece	—	Seven pence halfpenny.
The 12 sol piece	—	Six pence.
The 6 sol piece	—	Three pence.
The double piece	—	A penny.
The 6 liard piece	—	Three farthings.
The sol	—	One halfpenny.
The 2 liard piece	—	One farthing.
The liard	—	Half a farthing.

The livre or franc is a nominal value, equal to ten-pence English. The tenth part of a franc is called a decime, and the hundredth part of a franc is called a centime.

Spanish coins.—In Spain, and the states depending upon it, the gold coin is the pistole; above which are the double pistole and piece of four pistoles, and under it the half-pistole; to which must be added the castillans of gold. The silver money is the piastre, or piece of eight rials, and its diminutions; as also the simple rial, with its diminutions. The copper coins are the ochavos, or octavos, which are of two kinds; the one equal to only four maravedis, and ordinarily called quarta; the other double this, and called double quarta: and lastly the maravedis. It must be observed, that in Spain they have new money and old; the old current in Sevil, Cadiz, Andalusia, &c. is worth 25 per cent. more than the new current at Madrid, Bilboa, St. Sebastian, &c. This difference is owing to their king Charles II. who, to prevent the exportation of money, raised it 25 per cent, which however he was able to effect only in part, several provinces still retaining the ancient rate.

Value and proportion of the Spanish coin.

Quarto, 4 maravedis			
Octavo, or double quarta, 8 maravedis			
Rial, old plata, equal to	0	0	6¾
Piece of eight, or piastre	0	4	6
Pistole	0	16	9.3

Portuguese coins.—Those of gold are the moeda d'oro, or as we call it, moidore, which is properly their pistole; above this are doppio moedas or double pistoles, and quadruple species equal to five pistoles.—The silver coins are the crusada, pataca, or piece of eight, and vintem, of which they have two sorts, the one silver and the other billon. The ree is of copper, which serves them in accompts as the maravedis do the Spaniards.

Res, ree, or rez, equal to three-fifths of a farthing sterling

Vintem. 20 res

Cruzada, 26 vintems.

	l.	*s.*	*d.*
Mi-moeda, or half-pistole	0	13	6
Moeda d'oro, or pistole	1	7	0
Doppio moeda, or double pistole	2	14	0
Ducat of fine gold	6	15	0

Besides the above, they have also pieces of gold of the value of 3*l.* 12*s.*, 1*l.* 16*s.*, and other subdivisions.

Dutch coins.—Those of silver are crowns or dollars, ducatoons, florins, and schellings, each of which has its diminution. The stiver is of billon: the duyt and penny, of copper.

	l.	*s.*	*d.*
Ducat of Holland	0	9	3.2
Ducatoon	0	5	5.59
Patagon, or rix dollar	0	4	4.28
The three-guilder piece, or sixty stivers	0	5	2.46
The guilder-florin, or twenty stivers	0	1	8.08
The lion dollar	0	3	7.07

The schelling goes for six stivers, and the ortke is the fourth part of a stiver.

Flemish coins.—Those of gold are imperials, rides, or philips, alberts, and crowns; those of silver are philips, rix dollars, patagons, schellings, and guldens; and those of copper, patards.

	l.	*s.*	*d.*
Groat, 8 patards			
Single stiver	0	0	1½

	l.	s.	d.
Schelling	0	0	7¼
Gulden	0	2	0
Rix dollar, dollar, patagon	0	4	6
Imperial	0	11	9

The German, Dutch, and French coins are current here.

German coins.—Those of gold are ducats, which are of various kinds, oboli of the Rhine, and florins: of this last kind there are some likewise of silver, besides rix dollars, and izelottes, which are all of that metal.

	s.	d.
Ducat of the bishop of Bamberg	9	3.2
Ducat of Hanover	9	2.7
Ducat of Brandenburg	9	3.2
Ducatoon of Cologn	5	5.02
Rix dollar or patagon of Cologn	4	4.53
Rix dollar or patagon of Liege	4	7.48
Rix dollar of Mentz	4	7.27
Rix dollar of Frankfort	4	6.53
Rix dollar of the Palatinate of Nuremberg	4	7.55
Rix dollar of Lunenburg	4	6.65
Old rix dollar of Hanover	3	6.03
Old bank dollar of Hamburg	4	6.92
Rix dollar of Lubeck	4	7.54
Gulden of Hanover	2	4.14
Gulden of Zell	2	3.07
Gulden of Brandenburg	2	3.81
Gulden of Saxony	2	4.12

Italian coins.—The several states of Italy have several current moneys, though there are some common to all, such as the pistole of gold, and the ducatoon and florin of silver, which are of various weights, fineness, &c. The coins peculiar to Rome are the julios of silver, the pignatelle of billon, and the bayoco, demi-bayoco, and quadrine of copper. Venice has its sequins of gold; its justins, or ducatoons, and derlingues, of silver: Naples its carlins: Genoa, its croisats: Savoy and Piedmont, lys, or silver: this last state has its papyroles and cavales of billon.

Gold coins of Italy.

	s.	d.
The sequin of Venice	9	5.7
The old Italian pistole	16	7.6
Pistole of Rome, Milan, Venice, Florence, Savoy, Genoa	16	6.7
Double ducat of Genoa, Venice, and Florence	18	7.7
Single ducat of the same places	9	3.8

Silver coins.

The old ducat of Venice	3	4.50
The ducat of Naples	3	4.43
The ducat of Florence or Leghorn	5	4.62
The tarin, or fifth part of the ducat of Naples	0	8.09
The carlin, or tenth part	0	4.04
The escudi, or crown, of Rome, or piece of ten julios, or one hundred bayocos	5	1
The teston of Rome, or piece of three julios	1	6.32
The julio of Rome	0	6.10
The croisat of Genoa	6	6.74
Justine of Venice	4	9
Derelingue, one-fourth of the justine	1	2

Swiss coins.—Are ratzes and blazes of billon: the ratz equal to ⅞ of a penny sterling: and the blaze of Berne, nearly equal to the ratz.

The German, French, and Italian coins, are current here.

Polish coins.

	s.	d.
The golden ducat	9	2.1
The old silver dollar of Dantzic	4	6.27
The old rix dollar of Thorn	4	5.85
The rix dollar of Sigismund III. and Uladislaus IV. kings of Poland	4	6.4
Abra	1	0 ⅕
Roup	0	4 ¾
Groch	0	0 ⅚

Danish coins.

	s.	d.
The gold ducat	9	3.2
The horse	1	1 ½
The four mark-piece	2	8.23
Marc lubs	1	6
Schesdal, or two marks	3	0
Rix mark	0	11
Slet mark	0	9

Swedish coins.—Those of copper are the roustique, alluvre, mark, and money.

	s.	d.
A gold ducat is equal to	9	3.2
An eight-mark piece of silver	7	2
A four-mark piece	2	7
A christine	1	1 ½
Caroline	1	5 ¼

The Swedish money properly so called is a kind of copper, cut into little square pieces, or plates, about the thickness of three English crowns, and stamped at the four corners with the Swedish arms; and current in Sweden for a rix dollar, or piece of eight.

Muscovite coins.—The proper coins of Muscovy are,

	s.	d.
The copec of gold, worth	1	6$\frac{1}{11}$
Copec of silver, or denaing	0	1
Polusk	0	0½
Motofske	0	0¼
The ruble of silver, valued at	4	6
The cheroonitz of gold, called ducat by foreigners	9	6

Turkish coins.—The gold coins are zingerlees, worth two dollars two-thirds; and tomilees, worth two dollars and a half, reckoning each dollar at 108 aspers; the sultani, xeriff, and chequeens, each worth about 9*s.* 4*d.*, 5*d.*, or 6*d.*, sterling.

The silver ones are the asper, worth a trifle more than a farthing sterling; and the para, or medin, worth three aspers.

Coins of the coast of Barbary.—Though the general currency in these parts is Spanish dollars, French crowns, Hungarian ducats, and the Turkish golden sultanins, there are some coins struck by the kings or deys in their different territories.

At Morocco, the metacals are a sort of gold ducats made by the Jews at their pleasure, so that their standard is very uncertain.

There are also the blanquille of silver, worth 2¼*d.*; and the filours of copper, eight of which go to a blanquille.

At Algiers, the gold coins are sultanins and aspers; and burbas, of which six go to an asper. The dubla is silver, and worth about 4*s.* 6*d.* The rubie, median, and zian, are of gold, the first equal to 35 aspers, or 1*s.* 9*d.* and the last 100 aspers.

At Tunis, they have sultanins of gold, but heavier by one-third than those of Constantinople: the nasura of silver, cut nearly square: and du-blas and burbas, of the same value with those of Algiers.

Persian coins.—Are either of silver or copper: of the first kind are the

	s.	d.
Abassi, equal to	1	$4\frac{1}{2}$
Mamoudi	0	$8\frac{1}{4}$
Shakee	0	$4\frac{1}{8}$

The copper coins are the casbequi, or cabsequi, equal to 5-12ths of a penny sterling. The telac, or cherasis, is of gold, but it has no currency among the merchants, being only a medal struck by every king of Persia upon his accession to the crown.

Chinese coins.—Throughout the kingdom of China and Tonquin there are not properly any coins struck; instead of these they cut their gold and silver into little pieces, of different weights: those of gold are called goltschuts; those of silver the natives call leam, the Portuguese taels. Beside these they have a small money of lead mixed with the scum of copper, having holes in the middle to string them on for the ease of numbering; this species is called caxa, cas, and pitis; and the string, which usually holds 200, is called santa. There are two sorts of goltschuts, the one of 32 and 1-7th ounces, and the other but half as much. The tael, or leam, is equal to 6*s.* 8*d.* sterling. The caxa, cas, or pites, is one-third of a farthing; 300,000 of them are only worth about 56 guilders and 5 stivers of Holland.

Coins of Japan.—The Japanese strike coupants both of gold and silver; and copper pieces with holes in the middle, like those of China, six hundred of which make the tael. The other moneys, which they cut, like the Chinese, of different weights, are chiefly three: the largest of the weight of six reals, viz. 48 taels, the tael equivalent to 75 Dutch stivers; the second equal to six and a half, and the third to 1 and 1-16th.

Coupant of gold weighs one ounce six drachms; its figure is a long oval, the longest diameter about four inches, and the shortest half an inch: worth 6*l.* 12*s.* 6*d.*

Other coupants of gold, near one-third of the former, amounting to about 2*l.* 4*s.* 2*d.* Coupant of silver current at 4*s.* 6*d.*

Copper money seven-twelfths of a farthing.

Coins of Siam.—In the dominions of Siam are struck gold pieces five or six grains heavier than the half pistole of Spain: but these are rather pieces of curiosity than of use in commerce. Their silver coin is the tical or baat: the diminutions of which are the mayon or seling, $\frac{1}{4}$ of the tical; the fouang, $\frac{1}{2}$ of the mayon; the page, $\frac{1}{4}$ of the fouang; and clam $\frac{1}{2}$ of the page; there are also sompays, in value $\frac{1}{2}$ a fouang. The tical weighs 3 gross and 23 grains, which, reckoning the ounce of silver at $3\frac{1}{2}$ louis tournois, is 32 sols and 4 deniers of that money, as it weighs near half an ounce.

Coins of the coasts and islands of the Indies.—The principal, and those most generally current, are pagodos, rupees, larins, fanos or fanoms, and coupans, each of which are struck both of gold and silver. Besides these, there are also particular coins: as at Goa, St. Thomases of gold; at Surat, Agra, and the rest of Indostan, the pecha, or pessa, and doudus, all of copper; the basarucos and chedas, of tin. The gold pagodo is common on all the coasts of Coromandel, and almost the only one in use in the trade carried on there. The English make them at Fort St. George, and the Dutch at Negapatam, of the same standard and weight with those of the country. The value is 5*s.* The value of the silver pagodo is very different: the smallest are worth eight tangas, reckoning the tanga at 90 or 100 basarucos, 8*s.*

The gold rupee is worth 1*l.* 11*s.* 6*d.*

Silver rupee varies in fineness and value. There are three kinds current, viz. rupee sicca, worth at Bengal, 2*s.* 11*d.*

Rupee of Madras, 2*s.* $5\frac{1}{2}$*d.*

Rupee of Surat, 2*s.* 3*d.*

This is to be understood of the new rupees; for as to the old ones of each kind, their value is less; those of Madras are but equal to 1*s.* 11*d.* those of Surat 2*s.* and the siccas 2*s.* 4*d.*

Larin, in form of a cylinder, bent in two, and flatted at each end, worth 9*d.*

Fanoms of gold are of different fineness, weight, and value. The heaviest are not worth above 5*d.* or $5\frac{1}{2}$*d.* and the lightest little more than five farthings.

The silver fanoms are not worth at most above 2*d.*

St. Thomas, equal to 9*s.*

Pecha or pessa of copper, worth about $\frac{1}{2}$*d.*

Doudou, somewhat less than $\frac{1}{2}$*d.*

Basaruco, 1-5th of a farthing.

Cheda of pewter is of two kinds: the one octagonal, current at $1\frac{3}{4}$*d.*

The other round, at $\frac{3}{4}$*d.*

In the dominions of the Great Mogul are rupees, mamoudas, and pechas; the first, both of gold and silver; the second of silver alone; and the third of copper. There are others struck by the princes tributary to him, particularly a silver piece of the king of Matoucha, worth $\frac{1}{2}$*d.* a silver piece of the king of Ogden, worth 6*d.* a gold piece of the king of Achem, worth 1*l.* 3*s.* a gold piece of the king of Macasser, taken for a guilder.

Shells current for coin are, 1. Cowries, brought from the Maldives, and pass for $\frac{1}{130}$ of a penny sterling. The natives of the coast of Africa call them bouges. 2. Porcelaine, in America, a shell nearly on the same footing with the cowrie. 3. Zimbi, current particularly in the kingdoms of Angola and Congo.

Fruits current for coin are, 1. Cacao, among the Americans, fifteen of which are esteemed equivalent to a Spanish rial. 2. Maize, which has ceased to be current since the discovery of America by the Europeans. 3. Almonds, used in the East Indies, where cowries are not current. The value of these is higher or lower, according as the year is more or less favourable to this fruit; in a common year, an almond is worth about 1-20th part of a farthing.

For more on the subject of this article we would refer to Dr. Kelly's elaborate work, The Universal Cambist, just published.

MONEY (Paper). See BANK.

MO'NEYBAG. *s.* (*money* and *bag.*) A large purse (*Shakspeare*).

MO'NEYBOX. *s.* (*money* and *box.*) A till; repository of ready coin.

MO'NEYCHANGER. *s.* (*money* and *change.*) A broker of money (*Arbuthnot*).

MO'NEYED. *a.* (from *money.*) Rich in money: often used in opposition to those who are possessed of lands (*Locke*).

MO'NEYER. *s.* (from *money.*) 1. One

that deals in money; a banker. 2. A coiner of money.

MO’NEYLESS. *a.* (from *money*.) Wanting money; penniless (*Swift*).

MO’NEYMATTER. *s.* (*money* and *matter*.) Account of debtor and creditor (*Arbuthnot*).

MO’NEYSCRIVENER. *s.* (*money* and *scrivener*.) One who raises money for others (*Arbuthnot*).

MO’NEYSWORTH. *s.* (*money* and *worth*.) Something valuable (*L’Estrange*).

MO’NGCORN. *s.* (manȝ, Saxon, and *corn*.) Mixed corn: as, wheat and rye.

MO’NGER. *s.* (manȝeꞃe, Saxon, a trader.) A dealer; a seller (*Hudibras*).

MONGOZ, in mastiology. See LEMUR.

MO’NGREL. *a.* (from manȝ, Saxon, or *mengen*, to mix, Dutch.) Of a mixed breed.

MONILIA, in botany, a genus of the class cryptogamia, order fungi, consisting of moniliform filaments clustered into a head. Six species; of which four are stipitate, and two sessile: most of them indigenous to our own country.

MONILIFORM, in natural history, beaded like a necklace.

MONIMA, a beautiful woman of Miletus, whom Mithridates the Great married. When his affairs grew desperate, Mithridates ordered his wives to destroy themselves. Monima attempted to strangle herself, but when her efforts were unavailing, she ordered one of her attendants to stab her.

MO’NIMENT. *s.* (from *moneo*, Latin.) It seems to signify inscription in *Spenser*.

To MO’NISH. *v. a.* (*moneo*, Latin.) To admonish (*Ascham*).

MO’NISHER. *s.* (from *monish*.) An admonisher; a monitor.

MONI’TION. *s.* (*monitio*, Latin.) 1. Information; hint (*Holder*). 2. Instruction; document (*L’Estrange*).

MO’NITOR. *s.* (Latin.) One who warns of faults, or informs of duty. It is used of an upper scholar in a school commissioned by the master to look to the boys (*Locke*).

MO’NITORY. *a.* (*monitorius*, Lat.) Conveying useful instruction; giving admonition.

MO’NITORY. *s.* Admonition; warning (*Bacon*).

MONK anciently denoted a person who retired from the world to give himself up wholly to God, and to live in solitude and abstinence. The word is derived from the Latin *monachus*, and that from the Greek μοναχος, solitary; of μονος, *solus*, alone.

The original of monks seems to have been this: the persecutions which attended the first ages of the gospel forced some christians to retire from the world, and live in deserts and places most private and unfrequented, in hopes of finding that peace and comfort among beasts which were denied them among men. And this being the case of some very extraordinary persons, their example gave so much reputation to retirement, that the practice was continued when the reason of its commencement ceased. After the empire became christian, instances of this kind were numerous; and those whose security had obliged them to live separately and apart, became afterwards united into societies. We may also add, that the mystic theology, which gained ground towards the close of the third century, contributed to produce the same effect, and to drive men into solitude for the purposes of enthusiastic devotion.

The monks, at least the ancient ones, were distinguished into solitaries, cœnobites, and sarabaites. The solitary are those who live alone in places remote from all towns and habitations of men, as do still some of the hermits.—The cœnobites are those who live in community with several others in the same house, and under the same superiors.—The sarabaites were strolling monks, having no fixed rule or residence.

The houses of monks again were of two kinds, viz. monasteries and lauræ. (See MONASTERY and LAURA.) Those we call monks now-a-days are cœnobites, who live together in a convent or monastery, who make vows of living according to a certain rule established by the founder, and wear a habit which distinguishes their order. Those that are endowed, or have a fixed revenue, are most properly called monks, *monachi*; as the Chartreux, Benedictines, Bernardines, &c. The Mendicants, or those that beg, as the Capuchins and Franciscans, are more properly called religious and friars; though the names are frequently confounded.

The first monks were those of St. Antony; who, towards the close of the fourth century, formed them into a regular body, engaged them to live in society with each other, and prescribed to them fixed rules for the direction of their conduct. These regulations, which Antony had made in Egypt, were soon introduced into Palestine and Syria by his disciple Hilarion. Almost about the same time, Aones or Eugenius, with their companions Gaddanas and Azyzas, instituted the monastic order in Mesopotamia and the adjacent countries; and their example was followed with such rapid success, that in a short time the whole east was filled with a lazy set of mortals, who abandoning all human connections, advantages, pleasures, and concerns, wore out a languishing and miserable life, amidst the hardships of want, and various kinds of suffering, in order to arrive at a more close and rapturous communication with God and angels.

From the east this gloomy institution passed into the west, and first into Italy and its neighbouring islands; though it is uncertain who transplanted it thither. St. Martin, the celebrated bishop of Tours, erected the first monasteries in Gaul, and recommended this religious solitude with such power and efficacy, both by his instructions and his example, that his funeral is said to have been attended by no less than 2000 monks. From hence the monastic discipline extended gradually its progress through the other provinces and countries of

Europe. There were besides the monks of St. Basil (called in the east *calogeri*, from καλος γερων, good old man), and those of St. Jerom, the hermits of St. Augustine, and afterwards those of St. Benedict and St. Bernard; at length came those of St. Francis and St. Dominic, with a legion of others; all which see under their proper heads.

Anciently the monks were all laymen, and were only distinguished from the rest of the people by a particular habit and an extraordinary devotion. Not only the monks were prohibited the priesthood, but even priests were expressly prohibited from becoming monks, as appears from the letters of St. Gregory. Pope Syricius was the first who called them to the clericate, on occasion of some great scarcity of priests, that the church was then supposed to labour under: and since that time the priesthood has been usually united to the monastical profession in Roman catholic countries.

Monk fish, in ichthyology. See Squalus.

Monk's-hood, in botany. See Aconitum.

Monk's rhubarb. See Rumex.

MONKERY. *s.* (from *monk.*) The monastic life.

MONKEY, in mastiology. See Simia.

Monkey flower, in botany. See Mimulus.

Monkey's beard. See Adansonia.

MONKISH. *a.* (from *monk.*) Monastic; pertaining to monks (*Smith*).

MONMOUTH, the capital of the county of Monmouth in England, 129 miles from London.—It has its name from its situation at the conflux of the Monow or Mynwy, and the Wye, over each of which it has a bridge, and a third over the Frothy.—Here was a castle in William the Conqueror's time, which Henry III. took from John baron of Monmouth. It afterwards came to the house of Lancaster, who bestowed many privileges upon the town. Here Henry V. surnamed *of Monmouth*, was born. The famous historian Geoffrey was also born at this place. Formerly it gave the title of earl to the family of Carey, and of duke to king Charles the second's eldest natural son; but now of earl to the Mordaunts, who are also earls of Peterborough. It is a populous and well built place, and carries on a considerable trade with Bristol by means of the Wye. It has a weekly market, and three fairs. In 1801 the number of inhabited houses in Monmouth was 638, of inhabitants 3,345, of electors about 800. Lat. 51. 49 N. Lon. 2. 46 W.

MONMOUTHSHIRE, a county of England; anciently reckoned a part of Wales, but in Charles the Second's time taken into the Oxford circuit, and made an English county. It is bounded on the north by Herefordshire, on the east by Gloucestershire, on the south by the river Severn, and on the west by the Welch counties of Brecknock and Glamorgan. Its extent from north to south is about thirty miles, from east to west twenty-six, and in circumference 110. It is subdivided into six hundreds; and contains seven market-towns, 127 parishes. In 1801 it contained 8,948 houses, and 9,903 families; the whole population amounting to 45,582 persons. It sends only three members to parliament, that is, one for Monmouth, and two for the county. The air is temperate and healthy; and the soil fruitful, though mountainous and woody. The hills feed sheep, goats, and horned cattle; and the valleys produce plenty of grass and corn. This county is extremely well watered by several fine rivers; for, besides the Wye, which parts it from Gloucestershire, the Mynow, which runs between it and Herefordshire, and the Rumney, which divides it from Glamorganshire, it has, peculiar to itself, the Usk, which enters this county a little above Abergavenny, runs mostly southward, and falls into the Severn by the mouth of the Edwith; which last river runs from north to south in the western side of the county. All these rivers, especially the Wye and Usk, abound with fish, particularly salmon and trout.

MONNIER (Peter Charles Le), was born at Paris on the 20th of November 1715. The profession of his father, or the rank which he held in society, we have not learned; and we are equally ignorant of the mode in which he educated his son. All that we know is that young Monnier, from his earliest years, devoted himself to the study of astronomy; and that when only sixteen years of age, he made his first observation, viz. of the opposition of Saturn. At the age of twenty he was nominated a member of the Royal Academy of Sciences at Paris. In the year 1735 he accompanied Maupertuis in the celebrated expedition to Lapland, to measure a degree of latitude. In 1748 he went to Scotland with lord Macclesfield, to observe the annular eclipse of the sun, which was most visible in that country; and he was the first astronomer who had the pleasure to measure the diameter of the moon on the disk of the sun.

Louis XV. it is well known, was extremely fond of astronomy, and greatly honoured its professors: he loved and esteemed Le Monnier. "I have seen the king himself (says Lalande) come out of his cabinet, and look around for Le Monnier; and when his younger brother was presented to him on his appointment to the office of first physician, his majesty was pleased to wish him the merit and reputation of his brother the astronomer." All the remarkable celestial phenomena were always observed by the king, in company with Le Monnier. Thus he observed with him at his chateau of St. Hubert, the two celebrated transits of Venus through the disk of the sun in the years 1761 and 1769; as appears from the Memoirs of the Royal Parisian Academy of Sciences. It well deserves to be here recorded in what manner the king behaved during these important observations, and how little he disturbed his astronomers (the celebrated La Condamine being likewise permitted to observe the transit in his presence) in this occupation; the proper time for which, if permitted to pass by, could not be recalled. Le Monnier relates in his Dissertation, that "his majesty perceiving that we judged the last contacts to be of the greatest importance, a profound silence at that moment reigned around us." At the transit of Venus in 1769, the king allowed the marquis de Chabert, an intelligent and expert naval officer, who was just returned from a literary voyage to the Levant, to assist at the observation. In a court like that of Louis XV. so scrupulously observant of etiquette, these will be allowed to have been most distinguished marks of honour, and of royal favour and condescension.

In the year 1750, Le Monnier was ordered to draw a meridian at the royal chateau of Bellevue, where the king frequently made observations. The monarch on this occasion rewarded him with a present of 15,000 livres; but Le Monnier applied this sum of money likewise in a manner that redounded to the honour of his munificent sovereign and of his country, by procuring new and accurate instruments, with which he afterwards made his best and most remarkable observations. In 1742 the king gave him in Paris *Rue de la Poste*, a beautiful free dwelling, where, till the breaking out of the revolution, he resided, and pursued his astronomical labours, and where his instruments in part yet remain. Some of them the present French government has, at the instance of Lalande, purchased for the National Observatory. In 1751 the king presented him with a block of marble, eight feet in height, six feet in breadth, and fifteen inches in thickness, to be used for fixing his mural quadrant of five feet. This marble wall, together with the instruments appending to it, turns on a large brass ball and socket, by which the quadrant may be directed from south to north; thus serving to rectify the large mural quadrant of eight feet, which is immoveably made fast to a wall towards the south.

With these quadrants Le Monnier observed, for the long period of forty years, the moon with unwearied perseverance at all hours of the night. It is requisite, to be a diligent astronomer, to be able to conceive to what numberless inconveniencies the philosopher is exposed during an uninterrupted series of lunar observations. As the moon during a revolution may pass through the meridian at all hours of the day or night; the astronomer who, day after day, prosecutes such observations, must be prepared at all, even the most inconvenient, hours, and sacrifice to them his sleep and all his enjoyments. How secluded from all the pleasures of social intercourse, and how fatiguing such a mode of life is, those astronomers, indeed, know not who then only set their pendulum clocks in motion, when some of the eclipses of the sun, moon, or of the satellites of Jupiter, are to be viewed. At this time, and in the present state of the science, these are just the most insignificant observations; and an able astronomer, well supplied with accurate instruments, may every day, if he take into his view the whole of his profession, make more important and more necessary observations.

Le Monnier was Lalande's preceptor, and worthy of such a scholar; and he promoted his studies by his advice, and by every other means in his power. Le Monnier's penetrating mind, indeed, presaged in young Lalande, then only sixteen years old, what in the sequel has been so splendidly confirmed. In his twentieth year he became, on the recommendation of his preceptor, a member of the Royal Academy: and in 1752 he was proposed by him as the fittest person to be sent to Berlin, to make with La Caille's, who had been sent to the Cape of Good Hope, correspondent observations, for the purpose of determining the parallaxes of the moon, then but imperfectly known. Le Monnier lent his pupil for this expedition his mural quadrant of five feet. His zeal for astronomy knew no bounds. For this reason Lalande, in his Notice des Travaux du C. Le Monnier, says of himself: "Je suis moi-meme le principal resultat de son zele pour l'astronomie."

Le Monnier was naturally of a very irritable temper: as ardently as he loved his friends, so easily could he be offended; and his hatred was then implacable. Lalande, as he himself expresses it, had the misfortune to incur the displeasure of his beloved preceptor; and he never after could regain his favour. But Lalande's gratitude and respect for him always continued undiminished, and were on every occasion with unremitting constancy publicly declared: patiently he endured from him undeserved ill treatment; so much did he love and esteem his instructor and master to the day of his death. "I have not ceased to exclaim (writes Lalande), as Diogenes exclaimed to his master Antisthenes, You cannot find a stick strong enough to drive me away from you!"

What a noble trait in the character of Lalande, who in 1797 wrote likewise an eulogium on Le Monnier in the style of a grateful pupil, penetrated with sentiments of profound veneration and esteem for his beloved master; but Le Monnier would not read it. This is not the place to give a circumstantial account of this intricate quarrel; we shall only further remark, that Lalande was the warm friend and admirer of the no less eminent astronomer La Caille, whom Le Monnier mortally hated. An intimate friendship likewise subsisted between Le Monnier and D'Alembert; but Lalande had no friendly intercourse with the latter.

Among the scholars of Le Monnier may likewise be reckoned Henwart, the celebrated geometrician and professor of mathematics at Utrecht; who, in a letter to Von Zach, astronomer to the duke of Saxe Gotha, dated the 26th of May, 1797, says, "Le Monnier is a penetrating and philosophical astronomer: I learned much from him in Paris; though I lodged with the late De l'Isle, where I frequently made observations in company with

Messier. Le Monnier was the friend of D'Alembert; and consequently an opposer of Lalande."

This great man, who had, for some years, ceased to exist either for the science of astronomy, or for the comfort of his friends, died at Lizeaux, in the province of Normandy, in 1799, aged 84 years. He left behind him some valuable manuscripts, and a number of good observations; with respect to which he had always been very whimsical, and of which in his latter years he never would publish any thing. He had by him a series of lunar observations, and a multitude of observations of the stars, for a catalogue of the stars, which he had announced so early as the year 1741. The more he was requested to communicate his observations, the more obstinate he became; he even threatened to destroy them. At the breaking out of the revolution, Lalande was greatly alarmed for the safety of these papers; he wished to preserve them from destruction, and made an attempt to get them into his possession; but all his endeavours were in vain. He was only able to learn that Le Monnier had hidden them under the roof of his house. Le Monnier having been first seized with a fit of the apoplexy so early as the 10th of November 1791, Lalande apprehended, lest, if no one except himself should know where he had hidden his papers, the infirm old man might perhaps have himself forgot it. He hopes, however, that La Grange, who married his second daughter, may have some information concerning them. Le Monnier left behind him no son.

MONNIERIA, in botany, a genus of the class diadelphia, order pentandria. Calyx five-parted, the upper division long; corol ringent; filaments two; the upper with two anthers, lower with three; capsules five, one-seeded. One species only; a Guiana plant, with forked stem; ternate leaves; white spiked flowers.

MONOCEROS, unicorn, in astronomy, a southern constellation formed by Hevelius, containing in his catalogue 19 stars, and in the Britannic catalogue 31, viz. 0.0.0.7.10.14.

MONOCEROS, in zoology. See MONODON.

MONOCHORD, a musical instrument wherewith to try the variety and proportion of musical sounds.

The monochord, according to Boethius, is an instrument invented by Pythagoras, for measuring geometrically, or by lines, the quantities and proportions of sounds.

The ancient monochord was composed of a rule divided and subdivided into divers parts, whereon there was a string pretty well stretched upon two bridges at each extreme thereof. In the middle between both was a moveable bridge, called magas, by means of which, in applying it to the different divisions of the line, the sounds were found to be in the same proportion to one another, as the divisions of the line cut by the bridge were.

The monochord is also called the harmonical canon, or canonical rule; because serving to measure the degrees of gravity, and acuteness of sounds. Ptolemy examines his harmonical intervals by the monochord.

There are also monochords with divers strings, and a multitude of fixed bridges; but the use of all these may be supplied by one single moveable bridge; by only shifting it under a new chord or string, which is placed in the middle, and represents the entire sound, or open note, answering to all the divisions on the other bridges.

When the chord was divided into equal parts, so that the terms were as 1 and 1, they called them unisons; if they were as 2 to 1, octaves, or diapasons; when they were as 8 to 2, fifths, or diapentes; if they were as 4 to 3, they called them fourths, or diatessarons; if the terms were as 5 to 4, diton, or a greater third; if as 6 to 5, a demi-diton, or a lesser third; lastly, if as 24 to 25, demi-diton, or diesis.

The monochord, being thus divided, was properly what they call a system, of which there were many kinds, according to the different divisions of the monochord.

Lord Stanhope, who has paid much attention to the subject of musical temperament, has given the following description of a new monochord:

1. The wire is made of steel, which does not keep continually lengthening, like brass or iron. 2. The whole wire forms one straight horizontal line, so that the moveable bridge can be moved without altering the tension of the wire; which is not the case when the wire pulls downwards on the bridges. 3. The ends of the wire are not twisted round the two stout steel pins that keep it stretched; but each end of the wire is soft soldered in a long groove formed in a piece of steel, which goes over its corresponding pin. 4. One of these two steel pins is strongly fastened by a brass slider, which is moved by means of a screw with very fine threads, this screw having a large micrometer head minutely divided on its edge, and a corresponding nonius; whence the tension of the wire may be very exactly adjusted. 5. A slider is fixed across the top of the moveable bridge, and is moved by means of another screw with very fine threads. 6. The slider is adjusted to the steel rod or scale, by means of mechanical contact against projecting pieces of steel firmly fixed on that steel scale, at the respective distances specified in the monochord table. 7. Each bridge carries a metallic finger, which keeps the wire close to the top of such bridge, while the remainder of the wire is made to vibrate. 8. The vibrations of the wire are produced by touching it with a piece of cork with the same elastic force, and always at the distance of one inch from the immoveable bridge.

The Stanhope monochord, though very ingeniously constructed, is in some respects inferior to the monochord contrived by Mr. Atwood. In this gentleman's apparatus the string hangs vertically, its tension being regulated by a weight suspended at its lower extremity, a little below the place where the string comes into contact with a fixed pulley; the length of the string is terminated at top by a horizontal edge: the other point of termination, which in the common monochord, as well as in many musical instruments, and in the Stanhope monochord, is a bridge over which the string is stretched, is in this construction effected by two steel edges vertically placed, that are capable of approaching, or of receding from, one another, like the cheeks of a vice: these being fixed on a frame worked by micrometer screws, can be easily moved in the vertical direction, so as to alter the length of the string in any desired proportion: these edges are separated occasionally by a spring, in order to let the string pass freely through, when its length is altered, and are closed again, so as to press the string slightly when that length is properly adjusted. By means of this construction the alteration of the tending force, by the application of bridges, &c. is wholly avoided. The scale placed under the string of this monochord is divided into 100 equal parts, and each of these by a micrometer screw into 1000 equal parts; so that by the aid of a microscope and a proper index, the length of a given part of the string may be adjusted on the monochord true to the $\frac{1}{100000}$dth part of its whole length.

The following table contains the chief scales that have hitherto been computed. In column first is given the natural scale, or scale of perfect intervals. The second column contains a new tempered scale, which seems better adapted than any other to keyed instruments, when chiefly designed for lesson-playing, or playing without accompaniments. The third is a scale proposed by Mr. Emerson, in his Mechanics, and since recommended by Mr. Jones in his Physiological Disquisitions, and by Mr. Cavallo in the Philosophical Transactions for 1788. The fourth and fifth exhibit the systems of mean tones, and of equal harmony, calculated by Dr. Smith for instruments of a more perfect construction than those now in use.

Note.	Natural Scale.	Tempered Scale.	Emerson, Jones, &c.	Mean Tones.	Equal Harmony.

N.B. Mr. Jones proposes to have the two numbers which are denoted by stars respectively altered to the numbers 796 and 531.

The method of tuning any instrument by means of the monochord is as follows: First tune the C of the monochord to the concert pitch by means of a tuning-fork; next, put the middle C of the instrument in perfect unison with the C of the monochord: then move the sliding fret to the next division on the scale, and proceed in the same manner with all the several notes and half notes within the compass of an octave. When this is done with accuracy, the other keys are all to be tuned, by comparing them with the octave which is already tempered.—The monochord is here supposed to be made to the pitch of C; but this may be varied at the will of the constructor.

The curious reader who may wish for further information respecting the construction and use of monochords will be highly gratified in perusing the appendix of Mr. Atwood's Treatise on Rectilinear Motion, Mr. Jones's ingenious and entertaining observations on the scale of music, monochord, &c. in his Physiological Disquisitions, Lord Stanhope's Essay on tuning musical instruments, and some interesting papers by Lord Stanhope, Mr. Farey, and others, in various numbers of Tilloch's Philosophical Magazine. See also TEMPERAMENT, and TRUMPET (Marine), in this work.

MONOCOTYLEDONOUS PLANTS. Plants which have only one cotyledon or lobe in the seed; as grasses, palms, and liliaceous plants. Linnéus remarks that these are more properly acotyledonous, since the cotyledon continues within the seed.

MONO'CULAR. MONO'CULOUS. *a.* (μόνος and *oculus.*) One-eyed (*Glanville*).

MONOCULUM. A name given to the cæcum or blind gut by Paracelsus, because perforated only at one end.

MONOCULUS. (*monoculus*, from μονος, one, and *oculus*, an eye.) *Monopia.* A very uncommon species of monstrosity, in which there is but one eye, and that mostly above the root of the nose.

This term however is bad and unclassical, as compounded of two languages. *Monopia* is, on this account, a far better word.

MONOCULUS, in zoology, a genus of the class insecta, order aptera. Legs from four to eight, formed for swimming and very long; body covered with a crust or shell divided into segments: antennas four, two, or none: eyes one or two, approximate and fixed in the shell; feelers four, in continual motion when swimming; the hind ones very small and hook-shaped. Sixty-eight species, found chiefly in Europe, a few in India, commonly in muddy waters or ditches, frequently in sea-waters, often parasitic on fuci, confervæ, ulvæ, and other aquatic plants: many of them inhabit our own ditches or sea-coasts. They may be thus subdivided:

A. With a single eye and crustaceous body.

B. With a single eye and bivalve shell; antennas branched.

C. With a single eye and bivalve shell: antennas simple.

D. With a single eye and bivalve shell: antennas tufted at the tip.

E. With a single eye, and univalve shell: antennas two.

F. Shell univalve: eyes two, placed beneath.

G. Shell bivalve: eyes two, placed on the back.

H. Shell bivalve: eyes two: antennas capillary.

The greater part are minute insects, requiring the assistance of a microscope to investigate their separate organs; a few however deviate from this rule, and especially the two following:

1. M. polyphemus. Molucca or king-crab. Shell orbicular, the suture lunate and toothed behind: tail subulate and very long. Inhabits India, and is the largest known insect, sometimes growing to four feet in length from tail to snout. It is said to be generally found in pairs, the male and female swimming together.

2. M. apus. Shell oblong, truncate and serrate behind; tail ending in two bristles. Inhabits Europe, and is found in the stagnant waters of our own country.

In the new zoological system of Cuvier, Lamark, and Latreille, this genus is removed from the class of insects, and in conjunction with the cancer and oniscus genera, constitute an additional class denominated crustacea, under which term we have given a detailed statement of the new arrangement. See the article CRUSTACEA.

MONODON. Narwhal. In zoology, a genus of the class mammalia, order cete. Teeth two in the upper jaw, extending straight forwards, long, spiral; spiracle on the fore and upper part of the head. One species only, M. monoceros. Skin white, spotted on the head with black; without dorsal fin; two small pectoral fins: head small; eyes very minute. This animal is peculiarly distinguished from every other kind of whale by its very long horn-like tooth, which is perfectly straight, of a white or yellowish white colour, spirally wreathed throughout its whole length, and gradually tapering to a sharp point. It measures from six to nine or ten feet in length, and proceeds from a socket on one side of the upper jaw, having a large cavity at its base or root running through the greater part of its length. In the young animals, and occasionally in the full grown ones, especially in the males, there are two of these teeth, sometimes nearly equal and sometimes very unequal in length, seated close to each other at the base, and running nearly in parallel lines to their extremity. The skin is smooth; and there is a considerable depth of oil or blubber beneath it.

The narwhal chiefly inhabits the northern parts of Davis's Straits: its food consists of the

NATURAL HISTORY.

Muræna.
M. Ophis, Spotted Eel.

M. Helena.
or Roman Eel.

London, Published by Sherwood & Co. Paternoster Row, April 1st 1812.

smaller kinds of flat-fishes, actiniæ, medusæ, and other marine animals. It is principally seen in the unfrozen spots of the northern seas towards the coasts. To such places it resorts in multitudes for the conveniency of breathing, while at the same time it is certain of finding near the shores a due supply of food. It is taken by means of harpoons, and its flesh is eaten by the Greenlanders both raw, boiled, and dried: the intestines and oil are used as a food; the tendons make a good thread, and the teeth serve the purpose of hunting horns, as well as the more important one of building tents and houses: but before this animal was distinctly known to the naturalists of Europe they were held in high estimation, as the supposed horns of unicorns. Various medical virtues were also attributed to them, and they were even numbered among the articles of regal magnificence. A Danish throne is said to be still preserved in the castle of Rosenberg composed entirely of narwhal's teeth.

A specimen of this whale, measuring about eighteen feet, exclusive of the horn or tooth, was some time ago stranded on the coast of Lincolnshire, at no great distance from Boston, and was said to have been taken alive; so that the narwhal may, in consequence, be numbered among the rarer animals of British zoology.

Monodon spurius. Bastard narwhal. An animal nearly resembling the narwhal, but perhaps of a different genus, is given under this name in the Fauna Groenlandica of Fabricius. It has no teeth in the mouth, but from the extremity of the upper mandible two minute, conic, obtuse teeth project, a little curved at the tips, weak, and not above an inch long; body elongated, cylindric, black: pectoral fins two, dorsal fin minute, tail horizontal. Its flesh and oil are considered as very purgative: inhabits the main ocean, seldom approaching the shore. It has been very seldom taken alive, and must be ranked among the rarest of the whale or cete tribe.

MONODY, in ancient poetry, a mournful kind of song, sung by a person all alone, to give vent to his grief. The word is derived from μονος, alone, and αιδω, I sing.

MONŒCIA. (μονος, and οικος, a house.) The name of the twenty-first class in the Linnéan system; comprehending the androgynous plants, or such as produce male and female flowers, on the same individual, without any mixture of hermaphrodites.

MONOGAMY. (compounded of μονος, *solus*, and γαμος marriage.) The state or condition of those who have only married once, or are restrained to a single wife. See Polygamy.

MONOGLOSSUM. (anc. geog.) A marttown of the Hither India, situated on the Sinus Canthi, into which the Indus empties itself. Said to be Mangalor on the coast of Malabar. Lon. 74 E. Lat. 3 N.

MONOGRAM. A character or cypher, composed of one, two, or more letters interwoven; being a kind of abbreviation of a name, anciently used as a seal, badge, arms, &c.

MONOGYNIA. (from μονος, alone, and γυνη, a woman.) The name of the first order or subdivision in each of the thirteen first classes of the Linnéan system. Comprehending such plants as have one pistil, or stigma only, in a flower.

MO'NOLOGUE. *s.* (μονος and λογος.) A scene in which a person of the drama speaks by himself; a soliloquy (*Dryden*).

MO'NOMACHY. *s.* (μονομαχια.) A duel; a single combat.

MO'NOME, or Monomial. *s.* In algebra, a quantity that has but one denomination or name (*Harris*).

MONOMOTAPA, a kingdom on the eastern coast of Africa, bounded on the north by Monomugi, on the east by the Mosambique, on the south by Sofala and Manica, and on the west by unknown regions. It is watered by several rivers, of which Zambera is the chief. The air is temperate, and the soil fertile in rice and sugar canes, which last grow without cultivation. There are a great many ostriches and elephants, with several mines of gold and silver. The inhabitants are negroes, who have as many wives as they choose to take. Their religion is paganism; but they believe in one God who created the world. The army of the king consists only of foot, for they have no horses in the country. The Portuguese had a settlement here in 1560, but they were all murdered, or forced away. The houses are built of wood, and covered with plaster, but there are very few towns, of which Monomotapa is the chief. Lon. 27. 30 E. Lat. 19. 0 S.

MONOMUGI, a region of Africa, lying near the equator, between Abyssinia on the north, Zanguebar on the east, Monomotapa on the south, and Congo on the west. This country is very little known to the Europeans.

MONONGAHELA, a river of North America, which rises in Virginia, and running north into Pensylvania, meets the Allegany at Fort Pitt, where their united streams assume the name of Ohio. It is deep and gentle, and navigable for barges fifty miles from its mouth.

MONOPETALOUS COROL. In botany, a corol of only one petal. It may be cut deeply, but is not separated at the base. Exemplified in convolvulus, primula, &c.

The most remarkable forms of the monopetalous corol are the bell-shaped, funnel-shaped, salver-shaped, wheel-shaped, and labiate.

MONOPHYL PERIANTH. (μονος, and φυλλον, a leaf.) In botany, a monophyllous or one-leaved perianth. All in one; if cut, not separated to the base. As in datura, primula. Applied also to the involucre.

MONOPHYSITES. (from μονος, *solus*, and φυσις, *natura*.) A general name given to all those sectaries in the Levant, who only own one nature in Jesus Christ; and who maintain that the divine and human nature of Christ were so united as to form only one nature, yet without any change, confusion, or mixture of the two natures. The monophysites, however, properly so called, are the followers of Severus, a learned monk of Palestine, who was created patriarch of Antioch in 513, and Petrus Fullensis.

The monophysites were encouraged by the emperor Anastasius, but depressed by Justin and succeeding emperors. However, this sect was restored by Jacob Baradæus an obscure monk, insomuch that when he died bishop of Edessa, A. D. 588, he left it in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were seconded in Egypt and the adjacent countries by Theodosius bishop of Alexandria; and he became so famous that all the monophysites of the east considered him as their second parent and founder, and are to this day called jacobites, in honour of their new chief.

MONOPOLI, an episcopal town of Naples, in Terra di Bari, seated on the gulf of Venice, twenty-eight miles S. E. of Bari. Lon. 17. 37 E. Lat. 41. 20 N.

MONO'POLIST. *s.* (*monopoleur*, Fr.) One who by engrossing or patent obtains the sole power or privilege of vending any commodity.

To MONO'POLIZE. *v. a.* (μονος and ϖολεω.) To have the sole power or privilege of vending any commodity (*Arbuthnot*).

MONO'POLY. *s.* (μονοπωλια.) The exclusive privilege of selling any thing (*Shaks.*).

MONO'PTOTE. *s.* (μονος and πτωσις.) A noun used only in some one oblique case.

MONOSPERMOUS PLANT. A plant that has one seed to each flower. As in polygonum, and collinsonia. A monospermous or one-seeded plant.

MONOSPERMOUS BERRY. A one-seeded berry; called monopyrena by the older botanical writers.

MO'NOSTACH CAULIS. (μονος, and σταχυς, a spike.) In botany, a stem bearing a single spike.

MONO'STICH. *s.* (μονοστιχον.) A composition of one verse.

MONOSYLLA'BICAL. *a.* (from *monosyllable.*) Consisting of words of one syllable.

MONOSY'LLABLE, in grammar, a word that consists only of one syllable, and is composed either of one or more letters pronounced at the same time. The too frequent use of monosyllables has a very bad effect in English poetry, as Mr. Pope both intimates and exemplifies in the same verse, viz.

"And ten slow words oft creep in one dull line."

MONOSY'LLABLED. *a.* (from *monosyllable.*) Consisting of one syllable (*Cleaveland*).

MONOTHELITES. (compounded of μονος, single, and θελημα, will, of θελω, *volo*, I will.) An ancient sect, which sprung out of the Eutychians; thus called, as only allowing of one will in Jesus Christ. The opinion of the Monothelites had its rise in 630, and had the emperor Heraclius for an adherent: it was the same with that of the Acephalous Severians. They allowed of two wills in Christ, considered with regard to the two natures; but reduced them to one, by reason of the union of the two natures; thinking it absurd there should be two free wills in one and the same person. They were condemned by the sixth general council in 680, as being supposed to destroy the perfection of the humanity of Jesus Christ, depriving it of will and operation. Their sentiments were afterwards embraced by the Maronites.

MONOTONY, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tone. See READING.

MONOTROPA. Bird's nest. In botany, a genus of the class decandria, order monogynia. Calyxless; petals ten; the five outermost hollowed at the base, and producing honey; capsule five-valved, a fifth part of the fructification often wanting. Two species; one common to the pine woods of our own country; the other a North American plant, the orobanche of Catesby.

MONPAZIER, a town of France, in the department of Dordogne, eighteen miles S. W. of Sarlat. Lon. 0. 47 E. Lat. 44. 46 N.

MONREALE, a town of Sicily, in Val di Mazara. It was erected into a bishopric in 1183, which has been suppressed, and the revenues appropriated to the marine, and the defence of the island against corsairs. It is three miles W.S.W. of Palermo.

MONRO (Alexander), a celebrated physician, was born in Scotland in 1697. He studied at Leyden, and contracted an intimate friendship with Boerhaave. In 1719 he returned to Edinburgh, where he read lectures on anatomy. He died in 1767, after publishing some valuable works; as, 1. Osteology; 2. Anatomy of the Nerves; 3. Several papers in the Medical Essays of Edinburgh; 4. On the Success of Inoculation in Edinburgh.

MONRO (John), an eminent physician, was born at Greenwich in Kent, of a Scotch family, in 1715, and educated at Merchant Taylors' school, London, from whence he was removed to St. John's college, Oxford, of which he became fellow. He studied physic at various universities, and was honoured with his doctor's degree by that of Oxford while he was abroad. In 1757 he was appointed joint physician with his father to Bridewell and Bethlem hospitals. He published an excellent answer to Dr. Battie's treatise on Madness. He died in 1791.

MONRO (Alexander), an episcopal divine, was born in Rossshire in 1648, and educated at King's college, Aberdeen, where he was chosen professor of philosophy. In 1686 he was appointed principal of Edinburgh, and died in 1713. He wrote several pieces against the presbyterians.

MONS, an ancient, large, handsome, rich, and very strong city of the Austrian Netherlands, in Hainault. There is a chapter, consisting of thirty ladies of distinction, who have the liberty of leaving the community when they intend to marry. They have several manufactures, and a good trade. It was taken by the allies in 1709, and by the French in July 1746; but rendered back by the treaty of Aix-la-Chapelle, after the fortifications were demolished. It stands partly on a hill, and partly on a plain in a marshy soil, on the rivers Haine and Trouilli, by which the country about it may be overflowed at pleasure. It was taken by the French in 1794. Lon. 4. 31 E. Lat. 50. 25 N.

Mons sacer. (anc. geog.) A mountain of the Sabines beyond the Anio, to the east of Rome; whither the common people retired once, and again to avoid the tyranny of the patricians. From this secession, and the altar of Jupiter Terribilis erected there, the mountain took its name.

MONSEIGNEUR. (in the plural *Messeigneurs.*) A title of honour and respect used by the French in writing to persons of superior rank or quality, before the late abolition of all ranks. Dukes, peers, archbishops, bishops, and presidents *à la mortier*, were complimented with the title of Monseigneur. In the petitions presented to the sovereign courts, they used the term Messeigneurs.

MONSELEMINES, a people inhabiting that part of Biledulgerid which borders on the territories of the emperor of Morocco.

MONSIEUR. (in the plural *Messieurs.*) A term or title of civility used by the French in speaking to their equals, or those a little below them, answering to Mr. or Sir among the English. The republicans however have taken pains to abolish this with other titles of distinction, and endeavour to substitute for it the indiscriminating appellation of Citoyen.

Monsieur, absolutely used, was a title or quality appropriated to the second son of France, or the king's brother. The king was also called Monsieur; but that only by the children of France.

MONSONIA, in botany, a genus of the class monadelphia, order dodecandria. Calyx five-leaved; petals five; stamens fifteen, united, with the cup connecting them five-cleft; style five-cleft; fruit separating into five one-seeded capsules, each tipped with a long terminal awn. Five species, natives of the Cape, and bearing, in their flower, a considerable resemblance to the geranium. They should be treated as hardy green-house plants; and, as their seeds seldom ripen among us, they are best propagated by cuttings of the root.

MONSOON, a regular or periodical wind in the East Indies, blowing constantly the same way during six months of the year, and the contrary way the remaining six. In the Indian ocean the winds are partly general, and blow all the year round the same way, as in the Ethiopic ocean; and partly periodical, i.e. half the year blow one way, and the other half near on the opposite points; and those points and times of shifting differ in different parts of this ocean. These latter are what we call monsoons. The shifting of these monsoons is not all at once; and in some places the time of the change is attended with calms, in others with variable winds; and particularly those of China, at ceasing to be westerly, are very subject to be tempestuous; and such is their violence, that they seem to be of the nature of the West India hurricanes, and render the navigation of those seas very unsafe at that time of the year. These tempests the seamen call the breaking up of the monsoons.

Monsoons, then, are a species of what we otherwise call trade-winds. They take the denomination monsoon from an ancient pilot, who first crossed the Indian sea by means hereof;—though others derive the name from a Portuguese word, signifying motion, or change of wind and sea.

Lucretius and Apollonius make mention of annual winds which arise every year, *etesia flabria*, which seem to be the same with what in the East Indies we now call monsoons. For the physical cause of these winds, see Wind.

MO'NSTER. *s.* (*monstrum*, Latin.) 1. Something out of the common order of nature (*Locke*). 2. Something horrible for deformity, wickedness, or mischief (*Pope*).

To Mo'nster. *v. a.* (from the noun.) To put out of the common order of things (*Sh.*).

Monster, in anatomy, a *lusus naturæ*, or sport of nature, by which the young of any class of animals is born mis-shapen; either from deficiency, redundance, or confusion of parts.

To these might perhaps be added, without impropriety, another kind, in which there is neither redundance, nor deficiency, nor confusion of parts, but an error of place, as in transpositions of the viscera. But children born with diseases, as the hydrocephalus, or their effects, as in some cases of blindness from previous inflammation, cannot be properly considered as monsters, though they are often so denominated.

Of the first order there may be two kinds, redundance or multiplicity of natural parts, as of two heads and one body, of one head and two bodies, an increased number of limbs, as legs, arms, fingers, and toes; or excrescences or additions to parts of no certain form, as those upon the head and other parts of the body, and these are usually more or less important according to their size or the part where they grow. But as such excrescences, whatever may be their size, have, from their texture, a disposition to enlarge, and to assume a morbid action, it is become an established rule to extirpate them whenever it can be done with safety.

2d, Of monsters from deficiency or want of parts, the instances are less frequent than those of the former kind, as of the brain and back part of the head, or of the whole head, as in the acephalus; or of one eye, as in the monoculus; of the lip and palate, as in the hare-lip; of one or both arms; of the fore-arm or hand; of one or more fingers; of a portion or of the whole of the spinal processes of the vertebæ, as in the spina bifida; of the incomplete formation of the skin, most frequently at the navel, or some part of the abdomen; of the penis, especially of the prepuce; of one or both of the inferior extremities; of the heart, of the liver, spleen, or any of the abdominal viscera; of the lower part of the rectum, terminating before it reaches the anus; and many others.

3d, Monsters from confusion of parts, as when the whole body is in one mass (usually called a mole), in which various parts of the child are found lying together in apparent confusion; of parts adhering together, as of the fingers and toes; of the rectum, as in the closure of the anus: of the vagina; of the external or internal parts of generation, as in those called hermaphrodites; of the two inferior extremities connected together and terminating in a point; of the club foot; and many others.

As we are ignorant of the manner in which the primordial parts of a regular conception are formed and established, and, in many respects, of the order in which the various parts of a fœtus are unfolded or enlarged, it is not surprising that we should be ignorant also of the manner in which monsters or irregular births are generated or produced; though it is probable that the laws by which these are governed are as regular, both as to cause and effect, as in common or natural productions. Formerly, and indeed till within these few years, it was a generally-received opinion, that monsters were not primordial or aboriginal, but that they were caused subsequently by the power of the imagination of the mother, transferring the imperfection of some external object, or the mark of something for which she longed, with which she was not indulged, to the child of which she was pregnant; or by some accident which happened to her during her pregnancy. Such opinions, it is now said, were permitted to pass current, in order to protect pregnant women from all hazardous and disagreeable occupations, to skreen them from severe labour, and to procure for them a greater share of indulgence and tenderness than could be granted to them in the common occurrences of life. The laws and customs of every civilised nation have, it is added, in some degree, established a persuasion that there was something sacred in the person of a pregnant woman: and this may be right in several points of view; but these go a little way towards justifying the opinion of monsters being caused by the imagination of the mother. The opinion has been attempted to be disproved by common observation, and by philosophy, not perhaps by positive proofs, but by many strong negative facts; as the improbability of any child being born perfect, had such a power existed; the freedom of children from any blemish, their mothers being in situations most exposed to objects likely to produce them; the ignorance of the mother of any thing being wrong in the child, till, from information of the fact, she begins to recollect every accident which happened during her pregnancy, and assigns the worst or the most plausible as the cause; the organization and colour of these adventitious substances; the frequent occurrence of monsters in the brute creation, in which the power of the imagination cannot be great; and the analogous appearances in the vegetable system, where it does not exist in any degree.

We believe the older opinion to be more correct and philosophical than the newer. We have no doubt that it is well supported by an accumulation of facts that cannot be otherwise explained: while the whole that can be urged from those advanced above is (not that they are in opposition to it but) that they do not directly support it, and may be explained upon a different principle. The power of the mind which affects the capillaries of the skin, and makes us blush or turn pale, excites an ague or a perspiration, according to the feeling of the moment, may easily be conceived to exercise an influence upon the womb, which is the most subject to mental influence of all the organs of the frame.

MONSTRO'SITY. Monstruo'sity. *s.* (from *monstrous*). The state of being monstrous, or out of the common order of the universe (*Bacon. Shakspeare*).

MO'NSTROUS. *a.* (*monstrosus*, Latin.) 1. Deviating from the stated order of nature (*Locke*). 2. Strange; wonderful (*Shakspeare*). 3. Irregular; enormous (*Pope*). 4. Shocking; hateful (*Bacon*).

Mo'nstrous. *ad.* Exceedingly; very much. A cant term (*Bacon*).

MO'NSTROUSLY. *ad.* (from *monstrous.*) 1. In a manner out of the common order of nature; shockingly; terribly; horribly (*South*). 2. To a great or enormous degree (*Dryden*).

MO'NSTROUSNESS. *s.* (from *monstrous.*) Enormity; irregular nature or behaviour (*Sh.*)

MONT-ALBAN, a strong town of Spain, in the kingdom of Arragon, with a strong citadel; seated on the river Riomartin, 44 miles south of Saragossa, and 92 north by west of Valencia. Lon. 0. 30 W. Lat. 41. 9 N.

Mont-Blanc. See Blanc (Mont).

Mont-Didier, a town of France, in the department of Somme and late province of Picardy, where the kings of France formerly had a palace. It is seated on a mountain, 24 miles S.E. of Amiens, and 57 N. of Paris. Lon. 2. 34 W. Lat. 49. 39 N.

Mont-L'heri, a town of the Isle of France. 15 miles from Paris. Here are the remains of a tower, which may be seen at a great distance. Lon. 2. 0 E. Lat. 48. 38 N.

Mont-Louis, a town of France, in the department of the Eastern Pyrennees and late province of Rousillon. It is the capital of the French part of Cerdagna, and has a regular fortress, on a rock, at the foot of the Pyrennees, built in 1680, by Louis XIV. for the protection of the frontiers. It is 40 miles W.S.W. of Perpignan, and 430 S. of Paris. Lon. 2. 5 E. Lat. 42. 30 N.

Mont-Luet, a town of France, in the department of Ain and late province of Bresse, seated on the Seraine, 12 miles N.E. of Lyons, and 205 S.E. of Paris. Lon. 5. 8 E. Lat. 45. 49 N.

Mont-Luzon, a town of France, in the department of Allier and late province of Bourbonnois, seated on the Cher, 35 miles S.W. of Moulins, and 150 S. of Paris. Lon. 2. 45 E. Lat. 46. 22 N.

MONTABOUR, a small fortified town of Germany, in the electorate of Treves, between Coblentz and Limpurg. Lon. 7. 50 E. Lat. 50. 30 N.

MONTAGNIAC, a considerable town of Asia, in Natolia, and in the province of Bec-Sangel, on the sea of Marmora. It carries on a great trade, especially in fruits, and is seated on a bay of the same name, 12 miles from Bursa, and 60 S.E. of Constantinople. Lon. 29. 40 E. Lat. 40. 20 N.

MONTAGUE (Edward), Earl of Sandwich, who perished in the great Dutch fight in which the duke of York commanded in 1672. He translated the Art of Metals, in which is declared the manner of their generation, and the concomitants of them, from the Spanish, 8vo. His Letters have also been published, in 2 vols. 8vo.

Montague (Lady Mary Wortley), an ingenious English lady. She accompanied her husband, who was appointed ambassador, to Constantinople; and wrote an account of her travels, which is very entertaining. She is also celebrated for having introduced the practice of inoculation into England.

Montague (Edward Wortley), son of the preceding lady. He was an extraordinary character. When a boy at Westminster school he eloped, and was found in the disguise of a chimney-sweeper; afterwards he connected himself with a fisherman; and next he went as a cabin-boy on board a vessel to Spain, in which country he became servant to a mule-driver. In this situation he was discovered and restored to his friends, who sent him to the West Indies; on his return from whence he became a member of parliament, and behaved himself for some time in a manner suited to his rank. At length the fit of rambling returned, and he went to the East, where he adopted all the manners of the Turks, and died in 1776. He wrote, 1. Observations on the Rise and Fall of the Roman Empire; 2. An Examination into the Causes of Earthquakes.

Montague-island, one of the Hebrides, in the South Sea, near Sandwich Island. Lon. 138. 37 E. Lat. 17. 26 S.

MONTAIGNE (Michel de), a French gentleman, was born in Perigord in 1533. His father educated him with great care, and made him learn Latin as other children learn their mother-tongue. His tutors were Nicholas Gronchi, who wrote De Comitiis Romanorum: William Guerenti, who wrote on Aristotle; George Buchanan; and M. Ant. Muret. He was also taught Greek by way of recreation; and because some think that starting children out of their sleep spoils their understanding, he was awakened every morning with the sound of music. He was counsellor for a while in the parliament of Bourdeaux; afterwards made mayor of Bourdeaux. He published his Essays, so much known in the world, in 1580. Montaigne had a great deal of wit and subtlety, but no small share of conceit and vanity. The learned and ingenious are much divided in their opinion about his works. He died in 1592.

MONTALCINO, a small populous town of Italy, in Tuscany, and in the territory of Sienna, with a bishop's see. It is seated on a mountain, 17 miles S.E. of Sienna, and 44 S.E. of Florence. Lon. 11. 30 E. Lat. 45. 7 N.

MONTALTO, an episcopal town of Italy, in the Marca of Ancona; seated on the river Monacio, 10 miles north of Ascoli, and 45 south of Ancona. Lon. 13. 30 E. Lat. 44. 54 N.

MONTANINI (Pietro), called Petruccio Perugino, an eminent landscape painter, was born at Perugia in 1619. At first he was instructed by his uncle Pietro Barsotti; but was afterwards placed as a disciple with Ciro Ferri. Yet he did not long adhere to the manner of either of those masters, choosing preferably to study under Salvator Rosa; and he imitated the style of that celebrated painter with exceeding great success. The taste of his landscapes was generally admired; the rocks, situations, torrents, and abrupt precipices, were designed with spirit, and in a grand style; and his figures recommended themselves to the eye by a very uncommon correctness, propriety, and elegance. He died in 1689.

MONTANISTS, Christian heretics, who sprung up about the year 171, in the reign of the emperor Marcus Aurelius. They were so called from their leader Montanus, a Phrygian by birth; whence they are sometimes styled Phrygians and Cataphrygians.

Montanus, it is said, embraced Christianity in hopes of rising to the dignities of the church. He pretended to inspiration; and gave out that the Holy Ghost had instructed him in several points which had not been revealed to the apostles. Priscilla and Maximilla, two enthusiastic women of Phrygia, presently became his disciples; and in a short time he had a great number of followers. The bishops of Asia, being assembled together, condemned his prophecies, and excommunicated those who dispersed them. Afterwards they wrote an account of what had passed to the western churches, where the pretended prophecies of Montanus and his followers were likewise condemned.

The Montanists, finding themselves exposed to the censure of the whole church, formed a schism, and set up a distinct society under the direction of those who called themselves prophets. Montanus, in conjunction with Priscilla and Maximilla, was at the head of the sect.

MONTARGIS, a considerable town of France, in the department of Loiret and late province of Orleanois. Its mustard and cutlery are excellent; and from the river Loing is a navigable canal hence to the Seine. It is seated near a fine forest, 15 miles S. of Nemours, and 62 S. by E. of Paris.

MONTAUBON, a commercial town of France, in the department of Lot, lately the episcopal see of the province of Querci. The inhabitants amount to 40,000; and have manufactures of silk stockings and stuffs, serges, shalloons, &c. This town was taken from the Huguenots in 1629, and the fortifications were demolished. It is seated on an eminence, on the river Tarn, 20 miles N. of Toulouse, and 30 S. of Cahors.

MONTBAZON, a town of France, in the department of Indre and Loire and late province of Touraine, seated at the foot of a hill, on which is an ancient castle, 135 miles S.W. of Paris. Lon. 0. 45 E. Lat. 47. 1 N.

MONTBELLIARD, a strong town of France, capital of a principality of the German empire, of the same name, between the department of Doubs and that of Upper Rhine. It is seated at the foot of a rock, on which is a citadel. It was taken in 1674 by the French, who demolished the fortifications; but it was restored to the prince. It is seated near the Alaine and Doubs, 33 miles W. of Basle, and 45 N.E. of Besancon. Lon. 6. 50 E. Lat. 4. 31 N.

MONTBLANC, one of the highest mountains of the Alps, in Savoy, so called from its uncommonly white appearance. It is 15,662 feet above the level of the sea, which is 414 feet higher than the peak of Teneriff. The summit was deemed inaccessible till 1786, when Dr. Paccard ascended it. The French have given the name of this mountain to the conquered duchy of Savoy, as an eighty-fourth department of France.

Montblanc, a town of Spain, in Catalonia, 15 miles N. of Tarragona. Lon. 1. 5 E. Lat. 41. 10 N.

MONTBRISON, a town of France, in the department of Rhone and Loire and late province of Forez, seated on the Vezize, 40 miles W. of Vienne, and 250 S.E. of Paris. Lon. 4. 27 E. Lat. 45. 32 N.

MONTECCHIO, a considerable town of Italy, in the duchy of Reggio, 10 miles S. E. of Parma, and 8 N.W. of Reggio. Lon. 15. 54 E. Lat. 38. 8 N.

MONTE-FALCO, a town of Italy, in the territory of the church and duchy of Spalatto: seated on a mountain near the river Clitunno, 12 miles west of Spalatto. Lon. 12. 40 E. Lat. 42. 58 N.

Monte-Falcone, a town of Italy, in Venetian Friuli, with a castle, near the river Ponzano, 12 miles N.W. of Triest. Lon. 13. 0 E. Lat. 46. 4 N.

Monte-Fiascone, a populous town of Italy, in the territory of the church, with a bishop's see. It is seated on a mountain, near the lake Bolsena, 12 miles S.W. of Orvietto, and 45 N.W. of Rome. Lon. 12. 4 E. Lat. 42. 26 N.

Monte-Leone, a town of Naples, in Calabria Ulteriore. It was ruined by an earthquake in 1638, and is 12 miles N.E. of Nicotera.

Monte-Marana, a populous town of Naples, in Principata Ulteriore, seated on the Calore, 18 miles S. of Benevento. Lon. 15 0 E. Lat. 40. 48 N.

Monte-Peloso, an episcopal town of Naples, in Basilicata, seated on a mountain, near the river Basiento, 14 miles E. of Cirenza. Lon. 16. 28 E. Lat. 40. 46 N.

Monte-Pulciano, a town of Tuscany, with a bishop's see. It is seated on a mountain, near the river Chiana, in a country noted for excellent wine, 25 miles S.E. of Sienna, and 50 S. by E. of Florence. Lon. 11. 49 E. Lat. 43. 10 N.

Monte-Sancto, formerly Mount-Athos, a mountain of Turkey in Europe, on the gulf of Contessa. It is called Monte-Sancto, or Holy Mount, because there are 22 monasteries thereon, in which are 4000 monks, who never suffer a woman to come near them. It is 17 miles S. of Salonichi. Lon. 24. 39 E. Lat. 40. 27 N.

Monte-Santo, a town of Portugal, in Beira, 6 miles N. of Idanha a Velha.

MONTEGO, a seaport, on a bay of the same name, on the N. side of the island of Jamaica. In June 1795 a fire consumed an immense quantity of stores, and great part of the town. Lon. 78. 5 W. Lat. 18. 40 N.

MONTELIMAR, a commercial town of France, in the department of Drome, with an ancient citadel. The inhabitants, in the 16th century, were the first to embrace the reformed religion. It is seated in a fertile plain, 25 miles S. of Valence, and 325 S. by E. of Paris. Lon. 4. 55 E. Lat. 44. 33 N.

MONTEMOR-O-NOVO, a town of Portugal, in Estremadura, 50 miles E. by S. of Lisbon. Lon. 15. 0 E. Lat. 38. 42 N.

Montemor-o-velho, a town of Portugal, in Beira, with a castle, 10 miles S.W. of Coimbra, and 83 N. Lisbon. Lon. 8. 9 W. Lat. 40. 5 N.

MONTESA, a strong town of Spain, in Valencia, which is the seat of an order of knighthood of the same name. It is five miles N.W. of Xativa. Lon. 0. 30 W. Lat. 39. 0 N.

MONTESQUIEU (Charles de Secondat), baron, a most illustrious Frenchman descended from an ancient and noble family of Guienne, was born at the castle of La Brede, near Bourdeaux, in 1689. The greatest care was taken of his education; and at the age of 20 he had actually prepared materials for his Spirit of Laws, by well digested extracts from those immense volumes of civil law which he had studied, not barely as a civilian, but as a philosopher. He became a counsellor of the parliament of Bourdeaux in

1714, and was received president a mortier two years after. In 1721 he published his Persian Letters; in which, under the screen of Oriental manners, he satirized those of France, and treated of several important subjects by delicate and transient glances: he did not avow this publication; but was no sooner pointed out as the author, than zeal without knowledge, and envy under the mask of it, united at once against the Persian Letters. He was received into the French Academy in 1728; and having previously quitted his civil employments, he entirely devoted himself to his genius, and was no longer a magistrate, but a man of letters. Having thus set himself at liberty, he travelled through Germany, Italy, Switzerland, Holland, and England, in which last country he resided three years, and contracted intimacies with the greatest men then alive; for Locke and Newton were dead. The result of his observations was, that Germany was fit to travel in, Italy to sojourn in, England to think in, and France to live in. On his return he retired for two years to his estate at La Brede, where he finished his work On the Causes of the Grandeur and Declension of the Romans; which appeared in 1734. The reputation acquired by this last work only cleared the way for his greater undertaking, the Spirit of Laws, which was printed at Geneva in 2 vols. 4to. 1750. This was immediately attacked by the adversaries of his Persian Letters, in a multitude of anonymous pamphlets, containing all the reproaches to which a liberal mind is exposed from craft and ignorance. M. Montesquieu drew up a defence of this work; which for truth, moderation, and delicacy of ridicule, may be regarded as a model in its way. This great man was peaceably enjoying that fulness of esteem which his great merits had procured him, when he fell sick at Paris, and died on the 10th of February 1755.—The following character of this great man is drawn by lord Chesterfield: "His virtues did honour to human nature, his writings justice. A friend to mankind, he asserted their undoubted and unalienable rights with freedom, even in his own country; whose prejudices in matters of religion and government he had long lamented, and endeavoured, not without some success, to remove. He well knew, and justly admired, the happy constitution of this country, where fixed and known laws equally restrain monarchy from tyranny, and liberty from licentiousness. His works will illustrate his name, and survive him, as long as right reason, moral obligation, and the true spirit of laws, shall be understood, respected, and maintained." As to his personal qualities, we are told by his eulogist, M. d'Alembert, that "he was of a sweet, gay, and even temper. His conversation was spirited, agreeable, and instructive. Nobody told a story in a more lively manner, or with more grace and less affectation. He had frequent absence of mind; but always awakened from it by some unexpected stroke that re-animated the languishing conversation. Though he lived with the great, he retired whenever he could to his estate in the country, and there met his books, his philosophy, and his repose. Surrounded at his leisure hours with peasants, after having studied man in the commerce of the world, he studied him in those simple people, solely instructed by nature. With them he cheerfully conversed; he endeavoured, like Socrates, to find out their genius, and appeared as happy with them as in the most brilliant assemblies; especially when he reconciled their differences, and by his beneficence relieved them from their distresses."

The following interesting story we present on the authority of Mr. Muirhead of Glasgow, in his Travels in the Low Countries:

'A young man, named Robert, sat alone in his boat, in the harbour of Marseilles. A stranger had stept in and taken his seat near him, but quickly rose again; observing, that, since the master had disappeared he would take another boat. "This, Sir, is mine,"—said Robert,—"would you sail without the harbour?" "I meant only to move about in the bason, and enjoy the coolness of this fine evening.—But I cannot believe you are a sailor." "Nor am I—yet on Sundays and holidays I act the bargeman, with a view to make up a sum."—"What! covetous at your age!—your looks had almost prepossessed me in your favour."—"Alas! Sir, did you know my situation you would not blame me."—"Well—perhaps—I am mistaken—let us take our little cruize of pleasure, and acquaint me with your history."

'The stranger having resumed his seat, the dialogue, after a short pause, proceeded thus:—"I perceive, young man, you are sad—what grieves you thus?" "My father, Sir, groans in fetters, and I cannot ransom him. He earned a livelihood by petty brokerage, but, in an evil hour, embarked for Smyrna, to superintend in person the delivery of a cargo, in which he had a concern. The vessel was captured by a Barbary corsair, and my father was conducted to Tetuan, where he is now a slave. They refuse to let him go for less than 2000 crowns, a sum which far exceeds our scanty means. However we do our best—my mother and sisters work day and night—I ply hard at my stated occupation of a journeyman jeweller, and, as you perceive, make the most I can of Sundays and holidays. I had resolved to put myself in my father's stead; but my mother, apprized of my design, and dreading the double privation of a husband and only son, requested the Levant captains to refuse me a passage."—"Pray, do you ever hear from your father?—under what name does he pass?—or what is his master's address?"—"His master is overseer of the royal gardens at Fez—and my father's name is Robert at Tetuan, as at Marseilles."—"Robert—overseer of the royal gardens?"—"Yes, Sir."—"I am touched with your misfortunes—but venture to predict their termination."

'Night drew on apace. The unknown, upon

landing, thrust into young Robert's hand a purse containing eight double louis d'ors, with ten crowns in silver—and instantly disappeared.

'Six weeks had passed since this adventure, and each returning sun bore witness to the unremitting exertions of the good family. As they sat one day at their unsavoury meal of bread and dried almonds, old Robert entered the apartment, in a garb little suited to a fugitive prisoner, tenderly embraced his wife and children, and thanked them with tears of gratitude for the fifty louis they had caused remit to him on his sailing from Tetuan, his free passage, and a comfortable supply of wearing apparel. His astonished relatives eyed one another in silence. At length, madame Robert suspecting her son had secretly concerted the whole plan, recounted the various instances of his zeal. "Six thousand livres," continued she, "is the sum we wanted—and we had already procured somewhat more than the half, owing chiefly to his industry. Some friends, no doubt, have assisted him upon an emergency like the present." A gloomy suggestion crossed the father's mind. Turning suddenly to his son, and eyeing him with the sternness of distraction, "Unfortunate boy," exclaimed he, "what have you done? How can I be indebted to you for my freedom, and not regret it? How could you effect my ransom, without your mother's knowledge, unless at the expence of virtue? I tremble at the thought of filial affection having betrayed you into guilt. Tell the truth at once—and let us all die if you have forfeited your integrity." "Calm your apprehensions, my dearest father," cried the son, embracing him,—"no, I am not unworthy of such a parent, though fortune has denied me the satisfaction of proving the full strength of my attachment—I am not your deliverer—but I know who is.—Recollect, mother, the unknown gentleman who gave me the purse. He was particular in his enquiries. Should I pass my life in the pursuit, I must endeavour to meet with him, and invite him to contemplate the fruits of his beneficence." He then related to his father all that passed in the pleasure-boat, and removed every distressing suspicion.

'Restored to the bosom of his family, Robert again partook of their joys, prospered in his dealings, and saw his children comfortably established. At last, on a Sunday morning, as his son sauntered on the quay, he recognized his benefactor, clasped his knees, and entreated him as his guardian angel, as the saviour of a father and a family, to share the happiness of his own creation. The stranger again disappeared in the crowd—but, reader, this stranger was Montesquieu.'

Besides the works above-mentioned M. Montesquieu wrote several small pieces, as the Temple of Gnidus, Lysimachus, and Essay upon Taste, which is left unfinished. His works have been collected since his death, and printed at Paris in a splendid edition, in quarto. They have likewise all of them been translated into English.

Montesquieu, a town of France, in the department of Upper Garonne, 15 miles S.S.E. of Toulouse.

MONTESQUIOU, a town of France, in the department of Gers, 11 miles W.S.W. of Auch.

MONTETH. *s.* (from the name of the inventor.) A vessel in which glasses are washed.

MONTE VELINO, a mountain of Italy, supposed to be the most lofty part of the Appennines, and 8397 feet above the level of the Mediterranean. It is 46 miles N.E. of Rome.

Monte-Verde, a town of Naples, in Principato Ulteriore, with a bishop's see, 60 miles E. of Naples. Lon. 15. 42 E. Lat. 40. 51 N.

MONTEZUMA, the last emperor of Mexico, was a prince of noble qualities. He opposed the invaders of his country with firmness; but at last was seized by Cortes, who forced him to acknowledge himself a vassal of Spain. An insurrection taking place among the Mexicans, Cortes brought forth Montezuma dressed in his royal robes with a view to appease them. The unhappy monarch received two mortal wounds from arrows, of which he shortly after died. He left two sons who embraced the Christian religion, and Charles V. made the eldest Count de Montezuma, and gave him a considerable estate.

MONTFAUCON (Bernard de), a very learned Benedictine of the congregation of St. Maur, singularly famous for his knowledge in pagan and ecclesiastical antiquities, was born of an ancient and noble family in Languedoc, in 1655. He served for some time in the army; but the death of his parents mortified him so with regard to the world, that he commenced Benedictine monk in 1675, and applied himself intensely to study. Though Montfaucon's life was long, healthy, retired, and laborious, his voluminous publications seem sufficiently to have employed the whole; exclusive of his greatest undertaking, for which he will be always memorable. This was his Antiquité expliquée, written in Latin and French, illustrated with elegant plates, in 10 vols. folio; to which he added a supplement of 5 vols. more. He died at the abbey of St. Germain in 1741.

MONT-FERRAND. See Clermont.

MONTFERRAT, a duchy of Italy, bounded on the E. by the Milanese and the territory of Genoa, on the N. and W. by Piedmont, and on the S. by the territory of Genoa, from which it is separated by the Apennines. It is very fertile and well cultivated, abounding in corn, wine, oil, and silk; and is subject to the king of Sardinia. Casal is the capital.

MONTFORT, a town of France, in the department of Seine and Oise, 16 miles W. of Versailles. Lon. 2. 50 E. Lat. 48. 45 N.

Montfort, a town of France, in the department of Isle and Vilaine, 12 miles W. of Rennes. Lon. 1. 58 W. Lat. 48. 8 N.

Montfort, a strong town of the United

Provinces, in Utrecht, with an ancient castle, seated on the Yssel, seven miles S. by E. of Utrecht. Lon. 5. 0 E. Lat. 52. 4 N.

Montfort, a town of Suabia, capital of a country of the same name, subject to the house of Austria. It is 16 miles S. of Lindau and the lake of Constance. Lon. 9. 51 E. Lat. 47. 22 N.

Montfort-de-Lemos, an ancient town of Spain, in Galicia, with a magnificent castle, seated in a fertile country, 25 miles N.E. of Orense, and 55 S.E. of Compostella. Lon. 7. 9 W. Lat. 42. 28 N.

MONTGOLFIER (Stephen James), in biography, famous as the inventor of aerostatic balloons, was born at Annonay, thirty-six miles from Lyons, and there carried on an extensive manufacture of paper, in conjunction with his brother Joseph. They were distinguished for their ingenuity in this branch, and were the first in France who made the beautiful vellum paper. It is said, that the incident of covering a coffee-pot, in which water was boiling, with a spherical cap of paper, which rose in the air as the water heated, first gave him the idea of an air-balloon. Others affirm, that reflecting on the ascent of smoke and clouds in the atmosphere suggested the hint. However this were, it appears that Stephen, in the middle of November, 1782, made an experiment at Avignon with a bag of fine silk, of the shape of a parallelopipedon, and of forty cubic feet in capacity, to the aperture of which he applied burning paper till it was filled with a kind of cloud, when it ascended rapidly to the ceiling. This experiment was repeated by the two brothers at Annonay, with a success that induced them to form a machine of the capacity of six hundred and fifty cubic feet, which filled in like manner with smoke, ascended to the height of six hundred feet. They proceeded enlarging the experiment, till they had constructed a globe of linen, lined with paper, of the capacity of twenty-three thousand four hundred and thirty cubic feet, which, inflated with the smoke of straw and chopped wool, rose to an elevation of about six thousand feet. This power of ascent M. Montgolfier attributed not merely to the rarefaction of the air from the heat (which appears to be the true cause), but to a species of gas specifically lighter than the common air, supposed to be disengaged from the burning substances. When the event of these experiments was reported at Paris, the philosophers of that capital immediately thought of applying, for the purpose of inflation, a gas which they knew to be eight or ten times lighter than common air, namely inflammable air, and trials were immediately made upon that principle, which have proved highly successful. In the mean time Montgolfier continued to extend his plans, and on September 19, 1783, he exhibited before the king and royal family at Versailles a grand machine, near sixty feet high, and forty-three in diameter, which ascended with a cage, containing a sheep, a cock, and a duck, and conveyed them through the air in safety to the distance of above ten thousand feet. Emboldened by this success, M. Pilatre de Rozier first offered himself to undertake the hazardous adventure of an aerial navigation in a new machine of Montgolfier's, of still larger dimensions. After first ascending alone to the height of eighty-four feet, he again seated himself in the car with the marquis d'Arlandes, when they gave all Paris the astonishing spectacle of hovering in the air over that city for about nine minutes at the height of three hundred and thirty feet. This brilliant experiment caused the annual prize of the Academy of Sciences to be awarded to M. Montgolfier, and from that era, October 19, 1783, the atmosphere has been a new field of human daring. The first principle of ascent, however, though applied in various succeeding instances, gradually gave way to the safer and more efficacious one of a gaseous fluid permanently lighter than the air. In one unfortunate instance the two modes were combined, and the result was, that the balloon caught fire, and occasioned the death of the first adventurer, Pilatre de Rozier, and his companion Romain. Montgolfier was rewarded for his discovery by admission into the Academy of Sciences, the cordon of St. Michael, and a pension of two thousand livres. He died in 1799.

MONTGOMERY, the capital of a county of the same name in North Wales, 158 miles from London, took its name from Roger de Montgomery earl of Shrewsbury, who built the castle; but it is called by the Welsh Tre Valdwin, that is, Baldwin's town; having been built by Baldwin, lieutenant of the marches of Wales, in the reign of William I. The Welsh, after having put the garrison to the sword, demolished it in 1095; but Henry III. rebuilt it, and granted it the privileges of a free borough, with other liberties. It is a large and tolerably well built town, in a healthful situation and fertile soil. It sends a member to parliament, and has the title of an earldom. It had formerly a tower and castle; but they were demolished in the civil wars. It has a weekly market and four fairs. Lon. 3. 5 W. Lat. 52. 26 N.

MONTGOMERYSHIRE, a county of North Wales, 36 miles long, and nearly the same broad; bounded on the N. by Merionethshire and Denbighshire, on the N.E. and E. by Shropshire, on the S. by Radnorshire, on the S.W. by Cardiganshire, and on the W by Merionethshire. It contains five market-towns, and 47 parishes, nearly 50,000 inhabitants, and sends two members to parliament. Though barren and mountainous in many parts, it has a greater mixture of fertile vale and plain than several of the Welsh counties. Its riches proceed from its sheep and wool, the hilly tracts being almost entirely sheep-walks; and the flocks, like those of Spain, are driven from distant parts to feed on them during the summer. This county also affords mineral treasures, particularly lead; and it abounds with slate and lime; but there is no coal. Its principal rivers are the Severn, Vyrnew, and Tannat, which are remarkable for salmon.

MONTH, in chronology, one of the twelve parts into which a year is divided. In its proper acceptation, it is that space of time which the moon takes up in passing from any certain point to the same again, which is called a periodical month; or it is the space of time between two conjunctions of the moon with the sun, which is called a synodical month. That space of time which the sun takes up in passing through one sign, or twelfth part of the zodiac, is also called (but improperly) a month. So that there are two sorts of months; lunar, which are measured by the moon; and solar, which are measured by the sun. The lunar periodical month consists of 27 days, 7 hours, 43 minutes, 5 seconds: the lunar synodical month is 29 days, 12 hours, 44 minutes, 3 seconds, and 11 thirds. A solar month contains, upon a mean calculation, 30 days, 10 hours, 29 minutes, 5 seconds.

The Jews, Greeks, and Romans, made use of lunar synodical months; but, to avoid fractions, they consisted alternately of 29 or 30 days. The former the Romans called *cavi*, and the Greeks χοιλοι; the latter were termed *pleni* and πληρεις.

1. The Hebrew months were ranged differently in their sacred and in their civil year.

Order of the sacred year.

1 Nisan	Answering to our	March
2 Jiar		April

7 Nisan		March
8 Jiar		April
9 Sivan		May
10 Thammuz		June
11 Ab		July
12 Elul		August

These months, being lunar, cannot exactly answer to our solar months; but every Jewish month must be conceived to answer to two of ours, and partake of both. As these twelve lunar months consisted only of 354 days, the Jews, in order to bring it nearer to the true year, took care every three years to intercalate a thirteenth month into the number, which they called veadar, or the second adar. The new moon was always the beginning of the month; and it is said the Jews had people posted on elevated places, to give notice to the Sanhedrim as soon as she made her appearance. After this, proclamation was made by sound of trumpet, and "the feast of the new moon, the feast of the new moon," resounded amongst the people.

The ancient Hebrew months were of thirty days each, excepting the last, which consisted of thirty-five; so that the year contained 365 days, with an intercalary month at the end of 120 years, which, by absorbing the odd hours which remained at the conclusion of each year, brought it back nearly to its proper place. This regulation of the year was borrowed from the Egyptians.

2. The months of the Athenian year, as we have before observed, consisted alternately of twenty-nine or thirty days. The first month, according to Meton's reformation of the calendar, began with the first new moon after the summer solstice and was called hecatombæon, answering to the latter half of June, and the former half of July. The order of the months, with the number of days in each, are as follows:

1 Hecatombæon,	30
2 Metagilnion,	29
3 Boedromion,	30
4 Mæmacterion,	29

Each month was divided into three decades of days, called δεχημερα. The first was called Μηνος αρχομενȣ or ιϛαμενȣ, or the decade of the beginning of the month; the second was Μηνος μεσȣντος, or the decade of the middle; and the third was Μηνος φθινοντος, παυομενȣ or λεγοντος, the decade of the expiring month.

The first day of the first decade was termed Νεομηνια, because the first month began with the new moon; the second day was δευτερα ιϛαμενȣ; the third τριτη ιϛαμενȣ, &c. The first day of the second decade was πρωτη μεσȣντος, the second δευτερα μεσȣντος, &c. The days of this decade were also called πρωτη επι δεκα, δευτερα επι δεκα, &c. The first day of the third decade was πρωτη επ’ εικαδι; the second was δευτερα επ’ εικαδι, &c. i. e. the first, second, &c. after twenty, because the last decade began on the twentieth day. This decade was also counted by inversion thus; φθινοντος δεκατη the twenty-first; φθινοντος εννατη the twenty-second; φθινοντος ογδοη the twenty-third; and so of the rest to the last day of the month, which was called ενη και νεα, the old and the new, because one part of that day belonged to the old and the other to the new moon; but after the time of Demetrius, the last day of the month was called from him Δημητριας; it sometimes was named τριακας.

The Grecian months, thus consisting of twenty-nine and thirty days alternately, fell short of the solar year 11 days 6 hours. To remedy this defect the cycle of four years, called τετραετηρις, was invented. In this cycle, after the first two years, they added an intercalated month, called εμβολιμος, consisting of twenty-two days; and again, after the expiration of two years more, they inserted another month of twenty-three days, the fourth part of a day having in the space of four years amounted to a whole year. See YEAR.

3. The Roman year under Romulus consisted of ten months only, and began with March, which contained thirty-one days; then followed April,

which had 30, May 31, June 30, Quintilis 31, Sextilis 30, September 30, October 31, November 30, December 30. These ten months containing no more than 304 days, this account was in a short time found to be deficient. Numa Pompilius, therefore, took away one day from each of these six months, April, June, Sextilis, September, November, December; and to the six days thus obtained he added fifty-one, which was the number that Romulus's year, in his opinion, wanted to make it perfect. Numa had now fifty-seven days to dispose of; he therefore divided them, and constituted two other months, January and February; the former consisting of twenty-nine, and the latter of twenty-eight days. The month of January, which he placed at the winter solstice, he made instead of March to begin the year. Thus Numa's year consisted of 355 days: but this being found 11 days 6 hours short of the solar year, he made use of the intercalation of ninety days at the expiration of eight years perpetually; which number, being made up of the eleven days and a quarter, kept the year pretty well to its place. The beginning of the year in Julius Cæsar's time had anticipated its true place 67 whole days: these he intercalated betwixt November and December; so that the year consisted, for this one time, of fifteen months or 445 days. This reformation was called the Julian correction, and this year the year of confusion. At the end of twelve years, by the ignorance of priests, who did not understand intercalation, twelve days had been intercalated for nine. This was observed by Augustus Cæsar, and rectified by ordering twelve years to pass without any intercalary days. The order and succession of months was the same as that of Numa. But January, March, May, Quintilis, Sextilis, October and December, had each 31 days; April, June, September 30, and February, in common years, 28; but every fourth year, or bissextile, 29. This, with a very little difference, is the account observed at present. Quintilis, in compliment to Julius Cæsar, was called July, because in this month he was born; and Sextilis, in honour of Augustus, was called August; both which names are still continued. See YEAR.

Each month by the Romans was divided into kalends, nones, and ides, all of which were reckoned backwards. The kalends were the first day of the month. The nones fell on the seventh, and the ides on the 15th, of March, May, July, October; but in all other months the nones were on fifth, and the ides on the 13th. For the more easy comprehension of the Roman manner of dating, according to this division of the months, here follows a table.

	March, May, July, October.	January, August, December.	April, June, September November.	February.
1	Kalendæ	Kalendæ	Kalendæ	Kalendæ

N. B. Every leap year, February consisting of twenty-nine days, the 24th and 25th of that month are written sexto Kal. Mart.; hence leap year is called Bissextilis.

It is remarked by Camden, that "the old English, or Anglo-Saxons, could express most aptly all the conceptions of the mind in their own tongue, without borrowing from any:" of this, the names they gave to the months may be adduced as an example.

January. (Wulꝼe-Monað, Sax. i. e. Wolf-month.) Because in that month the wolves were most mischievous to them, for that, through the extremity of cold and snow, they could not find beasts sufficient to satisfy their ravenous appetites.

February. (Sꞃꞃouꞇ-Kele, Sax. i. e. Colewort, or Spring-wort.) Because then worts begin to sprout.

March. (Lencꞇ-Monað, Sax. i. e. Lengthening-month.) Because then the days begin in length to exceed the nights.

April. (Ooꞅꞇeꞃ-Monað, Sax.) Because their Easter generally fell in April.

May. (Tꞃı-Mılcı, Sax. i. e. Three-milkings.) Because they then milked their cattle three times a day.

June. (Meꝺe-Monað, Sax. i. e. Hay-month.) Because then they generally cut their hay.

August. (Aꞃn-Monað, Sax. i. e. Barn-month.) Because they then filled their barns.

September. (Leꞃꞅꞇ-Monað, Sax. i. e. Grist-month.) Because then they carried their new corn to the mill.

October. (Wyn-Monað, Sax. i. e. Wine-month.) Because grapes were then usually pressed to make wines.

November. (Wynꝺe-Monað, Sax. i. e. Windy-month.) Because of the high winds happening commonly in that month.

December. (Wynꞇeꞃ-Monað, Sax. i.e. Winter-month.) Because of the cold then growing intense; and afterwards, (Þælıᵹ-Monað, Sax. i. e. Holy-month) on account of the nativity of Christ.

Month's mind. *s.* Longing desire. (*Shak.*).

MO'NTHLY. *a.* (from *month.*) 1. Continuing a month; performed in a month. (*Bent.*). 2. Happening every month. (*Dry.*).

Mo'nthly. *ad.* Once in a month. (*Hook.*).

MONTIA. Water-chickweed. In botany, a genus of the class triandria; order trigynia. Calyx two-leaved; corol one-petalled, irregular; capsule one-celled, three-valved, three-seeded. One species only; common to the wet fields of our own country.

MONTI'NIA, in botany, a genus of the class dioecia, order tetrandria. Calyx four-toothed; petals four. Fem. style cloven; capsule oblong, two-celled; seeds numerous, flat. One species only; a Cape plant with shrubby angular stem; oblong-oval glabrous leaves; terminal, solitary flowers.

MONTMORENCI, a town of France, remarkable for the tombs of the ancient dukes of Montmorenci. It is seated on a hill, seven miles from St. Dennis, and ten from Paris.

MONTMORENCY (Anne de), constable of France, and one of the greatest generals of his age. He defended Menziers against Charles V. in 1512, and compelled the count of Nassau to raise the siege. He was taken prisoner with Francis I. at the battle of Pavia; and was mortally wounded in that of St. Dennis in 1567.

Montmorency (Charles de), third son of the preceding, was made admiral of France by Henry IV. for his bravery. He died in 1612, aged 75. This illustrious house produced more great men than any family in France.

MONTMORILLON, a town of France, in the department of Vienne, seated on the Gartempe, over which is a bridge, 24 miles S. E. of Poitiers.

MONTO'IR. *s.* (French.) In horsemanship, a stone as high as the stirrups, which riding-masters mount their horses from.

MONTPELLIER, one of the largest and most beautiful cities of France, in the department of Herault, with a citadel, a bishop's see, a university, in which is a celebrated school of medicine, and a late royal botanic garden, the first established in Europe. The cathedral was ruined by the Huguenots, but has been partly rebuilt. The number of inhabitants is computed at 32,000. The trade consists in silks, blankets, cotton goods, printed calicoes, gauzes, hides, cordials, perfumed waters, hair-powder, and verdigrise. The air is extremely healthy, and many invalids resort hither, from all parts, to recover their health. Montpellier is seated on a hill, five miles from the Mediterranean, near the Lez, a small navigable river, and on the rivulet Merdanson, which is conveyed into different parts of the city by subterraneous canals. It is 27 miles S.W. of Nismes, 47 N.E. of Narbonne, and 180 S. by W. of Paris. Lon. 3. 58 E. Lat. 43. 37 N.

MONTREAL, a fertile island of Canada, in the river St. Lawrence, 28 miles long and 10 broad. It was surrendered by the French to the English in 1760. It has a fortified town of the same name, built on the side of the river, whence there is a gradual easy ascent to what is called the Upper Town. It has suffered much by fires since it has been in the possession of the English. It is 110 miles N. of Albany, and 120 S. W. of Quebec. Lon. 71. 20 W. Lat. 45. 55 E.

Montreal, a town of Spain, in Arragon, with a castle, seated on the Xilcoa, 25 miles N.N.W. of Terruel, and 40 S. by E. of Calatajud. Lon. 1. 2 W. Lat. 40. 53 N.

Montreal, a town of Sicily, in Val di Mazara, with an archbishop's see; seated on a rivulet, five miles W. of Palermo, and 50 N.E. of Mazara. Lon. 13. 31 E. Lat. 38. 14 N.

Montreal, or Montroyal, a fortress of Germany, in the electorate of Treves, seated on the Moselle, 22 miles N.E. of Treves. Lon. 7. 6 E. Lat. 49. 59 E.

MONTREUIL, a strong town of France, in the department of the Straits of Calais, with a castle; seated on a hill, near the river Canche, 10 miles N.W. of Hesdin, and 117 N. of Paris. Lon. 1. 52 E. Lat. 50. 27 N.

Montreuil-Bellay, a town of France, in the department of Maine and Loire, seated on the Touet, 12 miles S.S.W. of Saumur, and 155 S.W. of Paris. Lon. 0. 9 W. Lat. 47. 6 N.

MONTRICHARD, a town of France, in the department of Loir and Cher, and late province of Blasois, with a castle. It is seated near the Cher, 12 miles S.E. of Amboise, and 112 S.W. of Paris. Lon. 1. 22 E. Lat. 47. 22 N.

MONTROSE, a handsome town of North Britain, in the shire of Angus, situated at the mouth of the river Esk, on the German ocean, 46 miles N.E. of Edinburgh, but 70 miles distance by road. The houses are neat, and many of them in the modern taste. The most remarkable public buildings are, the town house, the church, and an elegant episcopal chapel.—Montrose is a parliament town, and a dukedom in the family of Graham. It stands between two rivers, the south and north Esks, over which there have been lately built two very handsome bridges, at a great expence. The salmon fisheries on these rivers are very valuable, and form a good branch of commerce. The harbour is a fine semicircular bason, defended by a handsome stone pier. A great number of trading vessels belong to this port. The inhabitants of Montrose are about 8000.

MONTSAUJEON, a town of France, in the department of Upper Marne, 15 miles S.S.W. of Langres, and 145 S.E. of Paris. Lon. 5. 16 E. Lat. 47. 36 N.

MONTSERRAT, a mountain of Spain, in Catalonia, on which is a famous monastery and chapel, dedicated to the Virgin, resorted to by numbers of pilgrims. It is inhabited by monks of several nations, who entertain all that come out of devotion or curiosity, for three days, gratis. This mountain is said to be 10 miles in circumference, and 3300 feet above the level of the sea, towering over a hilly country, like a pile of grotto work, or Gothic spires. It is 25 miles N.W. of Barcelona.

MONTSERRAT, one of the Leeward Caribbee Islands, discovered in 1493 by Columbus, and so named by him from its resemblance to the mountain mentioned in the preceding article. It is about nine miles in length and breadth; and the hills are covered with cedar and other trees. It belongs to the English, and is 30 miles S.W. of Antigua. Lon. 62. 34 W. Lat. 16. 54 N.

MONT ST. MICHEL, a strong town of France, in the department of the Channel, built on a rock in the sea, which is ascended at low water. Its late Benedictine abbey served at once for a castle of defence, and a state prison, and was also much frequented by pilgrims. The prior of the abbey was governor of the town, and the keys were brought to him every evening. This place gave name to the late military order of St. Michel, founded by Louis XI. in 1479. It is 10 miles S.W. of Avranches, and 180 W. of Paris. Lon. 1. 30 W. Lat. 48. 37 N.

MONTUCLA (John Stephen), a celebrated mathematician, was born at Lyons, September 5, 1725. His father was a banker, and he was intended for the same profession; but the science of calculations to which he was introduced, soon indicated the natural bent of his mind. He was instructed in the ancient languages, and in the rudiments of mathematics, in the Jesuit's college at Lyons: and by his own private exertions obtained a competent acquaintance with the Italian, German, Dutch, and English languages; the latter of which he not only read, but also spoke very correctly. Having finished his studies at Lyons, he went about his twentieth year to Toulouse to study the law; a branch of knowledge then deemed essential in the liberal education of every person not destined for the profession of arms. From Toulouse he repaired to Paris, where he soon became acquainted with Diderot, Dalembert, Lalande, Blondel, Cochin, Leblond, Lagrange, &c. the society of whom riveted his choice for mathematics and natural philosophy. It was in relaxing and unbending his mind from his severer studies, that he in a manner made an entire new book of Ozanam's Mathematical Recreations; a work, which, with Montucla's improvements, has been translated into the English language by Dr. Hutton. Many other pieces were in an anonymous manner published by Montucla: among which we cannot omit mentioning an ingenious and learned History of Researches relating to the Quadrature of the Circle, published in 1754; a work very interesting on account of the number of speculators who have gone astray after that seducing phantom, and of the curious properties to which those researches have given rise.

Montucla and Condamine introduced into France, in 1756, the practice of inoculation for the small-pox, which had been brought into England in 1721, by lady Mary Wortley Montague, on her return from Constantinople. Montucla made a translation from the English of the principal writings on that subject, which he added to a memoir of Condamine.

In the year 1758 came out Montucla's grand work, the History of Mathematics, in two large quarto volumes: a work of profound erudition, and upon which, young as he was, he had spent many years. This performance of immense labour and knowledge, published at thirty-three years of age, justly procured the author a most distinguished place in the learned and scientific world. This history, so truly admirable, whether we consider the extreme clearness and precision with which the subjects are treated, or the profound learning it exhibits, having been long out of print, the author's employment under the old French government, as first commissary of the king's buildings, for many years prevented his fully yielding to the solicitations of his friends, to continue the work through the eighteenth century, in a new and enlarged edition. But the loss of his fortune and employment by the revolution in France left him but too much leisure for that purpose. The consequence, happy in this instance for the abstruse sciences, has been a new edition, in four large quarto volumes; in which the history is continued down to the end of the eighteenth century; and the former parts also very much enlarged and improved. This new edition, however, was not published till after the death of Montucla; and then under the superintendance of Lalande, who obtained some valuable additions from Lacroix and others.

In 1755 Montucla was elected an associate member of the academy of sciences at Berlin.

And in 1761 he was placed at Grenoble as secretary to the office of intendance; where he married Maria Françoise Romand, who survived him.

The duke de Choiseul having ordered, in 1764, a colony to be formed at Cayenne, Montucla went out there as secretary to the commission and astronomer royal. The affairs of the colony not proving successful, after fifteen months, Montucla returned again to Grenoble, bringing with him many useful observations and specimens in botany and natural history. This voyage also furnished him with those curious observations on the luminousness of the sea in many places, and of those luminous insects, which he inserted in the fourth volume of the later editions of his Recreations.

Soon after his return, Montucla was appointed at Versailles to the honourable and profitable office of first commissioner of the royal and public buildings; an employment which he executed with great ability and usefulness during more than twenty-five years, till the overthrow of the monarchy put an end at once to his office, and the little fortune his regularity and economy had enabled him to save; throwing him again on the world, in his old age, naked and stript of every thing except his talents, his integrity, and the respect and esteem of his friends.

Montucla's modesty and uprightness were not less remarkable than his erudition. He was offered a place in the Paris academy of sciences; which through delicacy he refused, as he felt that he should not have leisure sufficient properly to attend to the duties of it. Montucla was named a member of the National Institute from the time of its commencement: and the government of 1795 employed him in examining and analyzing the treatises deposited in the national archives. He was named professor of mathematics in the central school at Paris; but his bad state of health compelled him to decline the office: the department therefore honoured him with a place in the jury of central instruction. But a place in the national lottery office was the only resource for his family during two years. A pension of 2400 francs (100*l.*) was given him by the minister Neufchateau on the death of Saussure; but this he enjoyed only four months previous to his death, which happened December 18, 1799; and was chiefly occasioned, as often happens to literary and sedentary men, by a retention of urine. He left, besides his widow, a daughter married in 1783, and a son employed in the office of the minister for the interior.

Montucla was one of the most considerable mathematicians of the eighteenth century; being well acquainted with all the branches of the abstruse sciences. His taste, however, always pure and clear, and not at all vitiated by any fondness for ostentatious display, led him to prefer the pure and luminous methods of the ancient mathematicians; and to blame, in the French and the Germans, the great neglect of the same principles, which they evinced on all occasions by their uniform preference of the mere modern analysis. As a historian his principal characteristic was candour: he has been accused of giving way to national prejudices; but in this respect his conduct is infinitely less culpable than a subsequent historian in the same department—Bossut. Montucla translated in some of his days of leisure Carver's Travels in North America.

In the qualities of his heart Montucla was truly estimable: remarkably modest in his deportment; benevolent far beyond the means of his small fortune; breathing in all his conduct the delicacy of a fine taste, and the sweetness of virtue.

MO'NUMENT. *s.* (*monument*, French.) 1. Any thing by which the memory of persons or things is preserved; a memorial (*Raleigh*). 2. A tomb; a cenotaph (*Pope*).

MONUME'NTAL. *a.* (from *monument.*) 1. Memorial; preserving memory (*Pope*). 2. Raised in honour of the dead; belonging to a tomb (*Crashaw*).

MONYCHUS, in fabulous history, a powerful giant, who could root up trees, and hurl them like a javelin. He receives his name from his horse's feet, as the word implies.

MONZA, a town of Italy, in the Milanese, seated on the Lambro, eight miles N.E. of Milan. Lon. 9. 20 E. Lat. 45. 33 N.

MONTZINGEN, a town of Germany, in the circle of Upper Rhine, 12 miles W. of Creutznach, and 42 E. of Treves. Lon. 7. 14 E. Lat. 49. 50 N.

MOOD. *s.* (*modus*, Latin.) 1. The form of an argument. (See MODE). 2. Style of music (*Milton*). 3. The change the verb undergoes in some languages, to signify various intentions of the mind, is called *mood.* (See GRAMMAR). 4. (from *mod*, Gothic; moð, Sax.) Temper of mind; state of mind as affected by any passion; disposition (*Addison*). 5. Anger; rage; heat of mind (*Hooker*).

MO'ODY. *a.* (from *mood.*) 1. Angry; out of humour (*Shakspeare*). 2. Mental; intellectual (*Shakspeare*).

MOON, (*Luna*, ☽) in astronomy, one of the heavenly bodies, usually ranked among the planets; but with more propriety accounted a satellite, or secondary planet. Among the ancients, the moon was an object of prime regard. By the Hebrews she was more regarded than the sun, and they were more inclined to worship her as a deity. The new moons, or first days of every month, were kept as festivals among them, which were celebrated with sound of trumpets, entertainments, and sacrifice. (See Numb. xxviii. 11. x. 16. 1 Sam. xx. 5—18.) People were not obliged on these days to rest. The feasts of new moons were a miniature representation of the feast of trumpets, which was held on the first of the month Tisri, which was the beginning of the civil year. The Jews, not being acquainted with the physical cause of eclipses, looked upon them, whether of sun or moon, as signs of the divine displeasure. The Grecians looked upon the moon as favourable to marriage; and the full moons, or the times of conjunction of sun and moon, were held the most lucky seasons for celebrating marriages; because they imagined the moon to have great influence over generation. The full moon was held favourable for any undertakings by the Spartans, and no motive could induce them to enter upon an expedition, march an army, or attack an enemy, till the full of the moon. The moon was supposed both by Greeks and Romans to preside over childbirth. The patricians at Rome wore a crescent on their shoes, to distinguish them from the other orders of men. This crescent was called *Lunula*. Some say it was of ivory, others that it was worked upon the shoe and others, that it was only a particular kind of fibula, or buckle.

As all the other planets move primarily round the sun, so does the moon round the earth: her orbit is an ellipsis, in which she is retained by the force of gravity; performing her revolution round the earth, from change to change, in 29 days 12 hours and 44 minutes, and round the sun with it every year: she goes round her orbit in 27 days 7 hours 43 minutes, moving about 2290 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side toward us; and that her day and night taken together are as long as our lunar month.

The mean distance of the moon from the earth is 60½ semi-diameters of the earth; which is equivalent to 240,000 miles. The mean eccentricity of her orbit is $\frac{55}{1000}$ of her mean distance, or in miles 13000, which makes a considerable variation in that mean distance. Her diameter is to that of the earth as 100 to 365, as 11 to 40.15, or 2180 miles; its mean apparent diameter is 31 minutes 16½, and that of the sun 32 minutes 12 seconds. Its mean diameter, as seen from the sun, is six seconds.

The moon's surface contains 14,898,750 square miles, and its solidity 5,408,246,000 cubical ones. The density of the moon's body is to that of the earth as 48,911 to 29,214; to that of the sun, as 48,911 to 10,000; its quantity of matter to that of the earth, nearly as 1 to 39.15; the force of gravity on its surface is to that on the surface of the earth as 139.2 to 407.8; and the moon's bulk to that of the earth as $\frac{1}{50}$ to 1. The moon has scarce any difference of seasons; because her axis is almost perpendicular to the ecliptic.

The different appearances of the moon are very numerous: sometimes she is increasing, then waning; sometimes horned, then semicircular; sometimes gibbous, then full and round. Sometimes, again, she illumines us the whole night, sometimes only a part of it; sometimes she is found in the southern hemisphere, sometimes in the northern: all which variations having been first observed by Endymion, an ancient Grecian who watched her motions, she was fabled to have fallen in love with him. The source of most of these appearances is, that the moon is a dark, opaque, and spherical body, and only shines with the light she receives from the sun; whence only that half turned towards him at any instant can be illuminated, the opposite half remaining in its native darkness. The face of the moon, visible on our earth, is that part of her body turned towards the earth; whence, according to the various positions of the moon, with regard to the sun and earth, we observe different degrees of illumination; sometimes a large and sometimes a less portion of the enlightened surface being visible.

The motions of the moon are most of them irregular, and very considerably so. The only equable motion she has, is her revolution on her own axis, in the space of a month, or time in which she moves round the earth; which is the reason that she always turns the same face towards us.

This exposure of the same face is not so uniformly so, however, but that she turns sometimes a little more of the one side, and sometimes of the other, called the moon's libration; and also shews sometimes a little more towards one pole, and sometimes towards the other, by a motion like a kind of wavering, or vacillation. The former of these motions happens from this: the moon's rotation on her axis is equable or uniform; while her motion in her orbit is unequal, being quickest when the moon is in her perigee, and slowest when in the apogee, like all other planetary motions; which causes that sometimes more of one side is turned to the earth, and sometimes of the other. And the other irregularity arises from this: that the axis of the moon is not perpendicular, but a little inclined to the plane of her orbit: and as this axis maintains its parallelism in the moon's motion round the earth, it must necessarily change its situation in respect of an observer on the earth; whence it happens, that sometimes the one, and sometimes the other pole of the moon becomes visible.

The very orbit of the moon is changeable, and does not always persevere in the same figure: for though her orbit be elliptical, or nearly so, having the earth in one focus, the excentricity of the ellipse is varied, being sometimes increased, and sometimes diminished; viz. being greatest when the line of the apses coincides with that of the syzygies, and least, when these lines are at right angles to each other.

Nor is the apogee of the moon without an irregularity; being found to move forward, when it coincides with the line of the syzygies; and backward, when it cuts that line at right angles. Neither is this progress or regress uniform; for in the conjunction or opposition, it goes briskly forward; and in the quadratures, it either moves slowly forward, stands still, or goes backward.

The motion of the nodes is also variable; being quicker and slower in different positions.

The physical cause of the moon's motion about the earth is the same as that of all the primary planets about the sun, and of the satellites about their primaries, viz. the mutual attraction between the earth and moon. See ASTRONOMY. See also Newton's Principia, Vince's Astronomy, 4to., and Laplace's Mecanique Celeste.

New observations on the atmosphere, twilight, &c. *of the moon.*—M. Schroeter of the Royal Society of Gottingen has lately published a very curious and elaborate work in German, entitled, Selenotopographische Fragmente, &c. or Selenotopographical Fragments, intended to promote a more accurate knowledge of the moon's surface. The several maps of the moon, which have been delineated by Hevelius, Ricciolus, Cassini, and Mayer, are well known to every person conversant with astronomical subjects. See ASTRONOMY. These, however, are very defective. M. Schroeter has, therefore, devoted many years to this part of astronomy; and in the work of which we shall here present our readers with an abridged account, he has aimed at giving his own observations with such clearness and accuracy that they may be verified by less skilful astronomers than himself; he has set down the exact time and epoch of each observation, and minutely described every accessary circumstance of the moment, such as the libration of the moon, the precise limits of her luminous rays, and her diameter, together with the magnifying power of the astronomical instrument employed.

It must be confessed that the means within his reach were of the most ample kind: his thirteen and twenty-seven feet reflectors magnified two and three thousand times and even more; but finding that he gained in point of clearness in the image in most of his observations when he used eye-glasses of less power, he preferred an eye-glass which magnified 130 times for his thirteen feet telescope, and an eye-glass of 180 for his seven and twenty feet instrument.

In order to give an idea of the first three sections, which contain in twenty-eight chapters a very precise description of some particular regions of the moon, we shall present our readers with the following analysis.

The author informs us, that in order to examine the surface of the moon with advantage, he confined his enquiries to very small portions of the planet at a time which were illuminated under a very small angle of light. In this way he frequently discovered incomparably more with glasses of small power than with the most powerful instruments, when taking observations under much larger angles of illumination, i. e. when the rays of the sun arrive under a greater altitude at any given point in the moon.

It may sometimes happen that one astronomer does not see objects in the same light as another, although their instruments and the other circumstances were precisely similar: this does not always arise from the effects of the different angles of illumination under which the object is discovered, and the very different reflections which frequently result; but may also be ascribed to the accidental variations of the atmosphere of the moon, which are very frequent, or to other causes which must be investigated by actual observations of the planet itself. It has also more than once happened that M. Schroeter himself saw objects quite differently at one time and at another, and sometimes even he lost sight of them altogether, although he employed instruments of the greatest magnifying power. He cites as an example of this anomaly, an observation upon the spot of Gassendi, which he has represented by two drawings of different dates. He remarks a great number of these accidental variations observed at various points in the moon's disk, and takes occasion to offer some conjectures, which are perhaps worthy of being repeated.

On the 1st November, 1791, for instance, he saw the crater which forms the centre of Possidonius under the appearance of a tolerably uniform circular plain of a greyish colour, without any darker shade, while the seven craters surrounding it were very deeply shaded. Next day in the evening the same object, seen with the same telescope, shewed itself as a profound crater, with obscure shades, although, if it could have been judged by the direction of the solar rays upon this part of the moon, the shadows ought to have appeared longer and stronger that evening than the day before. Nothing but an accidental cause could have altered the apparent form of the crater in twenty-four hours, whether we attribute this accident to a change in the atmosphere of the moon, or to a fermentation in its interior, or to the actions of some animated beings who inhabit it.

In this same region of Possidonius, M. Schroeter saw with the greatest precision on the 4th of June, 1794, in a clear and calm day, five new objects: whether these were new craters, or chains of mountains which he had not seen before, he never observed them since.

On the other hand, he could not recognise with the twenty-seven feet telescope the crater which he had previously and repeatedly observed with the seven feet telescope; this he attributes to a variation in the atmosphere of the moon. He also observed with a thirteen feet reflector a new production, which unexpectedly appeared in a very distinct manner, in a crater, on the 6th of February, 1797, although in the course of nine years of anterior observations made with the best instruments, he had never discovered the least trace of such a phenomenon. This new production had in all probability made its appearance between the 12th of October, 1796, and the 6th of February, 1797. Subsequent to this last period, it had generally been visible under very different, and sometimes unfavourable angles of illumination; and yet other variable appearances were exhibited, particularly subsequent to the 4th of July, 1797, at which period this new crater was confounded in a mass of atmospheric fermentation, and perhaps new eruptions ensued.

In order to render more sensible the different forms under which the various objects in the moon may present themselves to the astronomical observer, and according to the accidental variations of the atmosphere of this planet, the author represents the landscape around Lilienthal, the place of his residence, as seen from the moon in the month of July, when the inhabitants of these environs burn the wrack off their fields, and when a thick smoke is spread over the ground. An observer placed in the moon at this period would see a grey envelop extended over that part of the north of Germany, an appearance which would not take place under any other circumstances. M. Schroeter is of opinion, that the crater of Possidonius, as already mentioned, having appeared grey on the 1st of November, and of an obscure black next day, may be ascribed to similar circumstances. In this former volume he had spoken of a great number of luminous points in the obscure hemisphere of the moon, subject to variations which had not for their only cause the differences in the reflection of the light of the earth. All these facts have now been confirmed by the help of great reflectors, and particularly in the luminous spots Aristarchus, Manilius, and Menelaus, in which the author has found at certain times distinct objects, and at others has not been able to discover even the objects themselves. The following luminous appearances appear to be somewhat remarkable: on the 2d of April, 1794, at eight o'clock in the evening, the obscure part of the disk being very distinctly visible, M. Schroeter discovered near the western boundaries of the sea of vapours (*mare vaporum*), in opposition to the dull light of the other parts, a luminous point extremely brilliant, which equalled a fixed star in lustre, and which the author had never perceived at that particular spot. It was evident, at the first glance, that this light could not have been reflected from the earth, and, in fact, in half an hour or less this brilliant point vanished so completely that it could no longer be recognized, and the author frequently afterwards conjectured that it no longer existed in the same place, but a similar point shewed itself towards the west. The kind of meteor which thus vanished is an appendage to the phenomenon observed long before in the spot of Plato in the Alps of the moon, when upon the 26th of September, 1788, M. Schroeter feebly discerned a similar luminous point, and found that it began to be less and less discernible until it disappeared, nor did he see it again for twelve years. This former phenomenon in the Alps of the moon may have been the effect of a very active effort of nature, and the new phěnomenon which happened in the milder temperature of the sea of vapours may rather be considered as the effect of a voluntary or involuntary action of the inhabitants of the moon. An illumination at London; a city on fire; the flashes of gunpowder from a besieged fortress, seen from the moon with M. Schroeter's reflectors, would present a spectacle similar to these luminous evanescent appearances seen from the earth upon the surface of its satellite. The Sea of the Crisis, in particular, which is one of the most remarkable places upon the surface of the moon, is thickly strewed with luminous points, which seem to belong to a plain abounding in asperities, natural or artificial.

Besides several high mountains, the exact measurements of which are here given, the author has discovered in several places of the moon, for instance in Possidonius, small elevations which are nearly fifty feet in height, and even less; an innumerable quantity of similar asperities is also to be found at a small distance from Marius. These eminences are not constantly visible, and their form is variable.

In the sea of vapours near Plato, and in other places, M. Schroeter discovered deep furrows, or a kind of long narrow valley resembling a canal. This phenomenon extends for seventy geographic miles into the sea of vapours. We are acquainted with no sublunary valley of so great a length. It is somewhat singular that this valley stretches over inequalities of mountains and craters in such a manner, that the upper ridge of these eminences is intersected by the furrow or valley in question. Can this be a production of nature, or of the free agency of animated beings? Such is the question put by M. Schroeter to his readers; and his observations seem to place it beyond a doubt that the moon has not at its surface any fluid so dense as the water of our earth; and he has also apparently demonstrated that his favourite planet has no considerable rivers, nor natural basins which serve to contain water, as in this sublunary world; but it does not follow from all this that the moon is a chalky body entirely dry; these long vallies or canals may perhaps contain rivers which have the same relative density to the subtle atmosphere of the moon, that is observed between water and our terrestrial atmosphere. Thus, in a certain sense, we may say that the moon has its rivers Plata and Amazon. Throughout these lunar Alps, (a chain of mountains equally continuous with those of Europe) we find the valley or furrow above mentioned stretching like a narrow pass, as if a violent convulsion of nature had cleft the mountains in a straight line.

In the fourth section, which contains observations upon the structure of the moon, the first chapter treats of the eminences and depression of that planet, and of its craters and vallies in general. The highest mountains, as the author had formerly estimated, are five times higher than the mountains of our globe, keeping in view the relative diameters of the two planets. The highest mountains of Venus and Mercury are, with respect to the mountains in the moon, nearly in the proportion of the relative diameters of these planets. The greatest height, according to the former observations of M. Schroeter, was to be met with in some peaks of the chains of mountains known by the name of Leibnitz and Dorfelsh, towards the south pole of the moon; and in the eastern parts of the southern hemisphere, in the mountains D'Alembert and De Rook. The height of the latter is from 24 to 25,000 feet, and none so high have been as yet observed in the northern hemisphere. The eclipses of the sun afford opportunities of observing directly the vertical altitudes of the mountains of the moon which are exhibited upon its obscure edge. An observation in these circumstances succeeded with the author at the time of the great eclipse of the sun, September, 1793. Immediately after its commencement he observed some summits of mountains projecting from the edge of the moon's disk, which, in their vertical height alone, and in the extent to which they were seen (for the lower extremities were lost in obscurity), must have been 3,000 geographical miles high. During this remarkable eclipse, Herschel also discovered two summits of mountains which were projected upon the edge of the sun. The spherical form of the moon projected upon this edge was remarked by M. Schroeter and by all his pupils with the utmost precision; at the distance of one minute from the limb, what was observable of this spherical form gradually disappeared: a phenomenon which M. Schroeter endeavours to account for in another place by remarking, that the light of the earth was considerably increased by the solar penumbra, and by the crepusculum.

The depth of some craters of certain hollows, which are not circular, extends, according to the author, to the depth of three quarters of a mile. A short distance from the high mountain Rook, we find a hollow called Christopher Milius, the vertical depth of which is at least 15 or 16,000 feet. The Chimboraco of our globe might be wholly swallowed up in this cavity. Craters in general are formed by eruptions from the interior; they are empty basins, from which the mass that surrounds them in the form of a ring has been vomited; but in the moon there are cavities of another kind, such as those of Milius and others already named, presenting irregularities of a circular form in the edges of the moon, between the interstices of which we can see the clear sky; there are some parts in the moon which are sunk by some powers of nature, vallies hollowed out, not merely upon the surface of that planet, but dug as it were into its mass: i. e. greatly below its mean surface. The fixed stars we perceive in the vicinity of these hollows of the moon may for this reason appear sooner or later by a few seconds in their emersions or immersions, than when they exist opposite those portions of the edge which are not irregular. The author, by referring to these sinuosities, ingeniously accounts for the pretended hole, which in the total eclipse of the sun on the 14th of June, 1778, was observed by admiral Ulloa. There could not possibly have been a volcano in the moon at that period, for it would have thrown out so glaring a light, that the luminous point must necessarily have been perceived in the black glass of the telescope upon the moon's disk. But the sun, when seen through a similar fissure, must have appeared as if seen through a hole, in the event of the direction of the fissure being oblique to that of the luminous ray. M. Schroeter, therefore, upon remarking that this fissure exists in the lunar region where the observation of Ulloa was made, and that it exists in that place alone, gave it the name of the above admiral. M. Schroeter proceeds to draw the following inferences.

"The greatest eminences of 25,000 feet and upwards, and the deepest hollows of three quarters of a geographical mile in depth, are situated in the southern part of the moon; hence we may conclude from actual observations, that in the moon, as upon the earth, and in the planets Venus and Mercury, the southern hemisphere is generally the most unequal and irregular.

"As the gravitation at the surface of the moon is only, according to theory, about one-fifth of that which takes place on the earth, we may say that, with regard to the relative diameters of the two planets, the mountains of the moon are five times higher than those of the earth, as has been already remarked.

"In our globe earthquakes are extremely rare, and still more rarely do they produce complete eruptions, such as islands or new mountains: the solid mass of the earth opposing too much resistance to these formations. It is otherwise with the moon, where the gravity is five times less, and where explosive effects always meet with less opposition; thence it follows, that the whole surface of the moon is almost always in a state of revolution; explosions, earthquakes, and other convulsions, follow each other in dreadful successions. New objects appear and vanish almost while the astronomer has his eye at his telescope. Hence proceeds that innumerable heap of craters, the second formation encroaching upon the first, the third effacing the two former, while at each eruption the preceding one is overwhelmed even before it has attained its destination."

Our readers will at once perceive the total discrepancy between this terrific description of the revolutions of the lunar world, and the fantastic idea attempted to be inculcated by M. Schroeter that there are animated beings, with houses, palaces, cathedrals, and tea-kettles, in the moon, as well as upon our planet. All these creatures of our astronomer's imagination must indeed be *sui generis.*

The fourth chapter of the second section is filled with enquiries into the atmosphere of the moon, its morning and evening crepusculum, the height and density of the air in that planet, &c. The author in his former volume had placed beyond a doubt the existence of an atmosphere which had been denied to that planet; he had mentioned a number of appearances in which some objects, in other respects identical, had appeared sometimes under one form, and at other times under another; while sometimes they were not visible at all: he had proved that this atmosphere of the moon, although much more subtle and transparent than ours, had the power of weakening, in a remarkable manner, the light of the sun descending under the lunar horizon; at which period, the summits of some mountains, being in this light on the obscure side of the moon, visibly threw out a lustre so much the more brilliant, as they were more distant from the edge of illumination, i. e. projected farther forward into the obscure part of the disk. All this, however, only gave rise to a conjecture as to a real refraction of the rays of light, whence there resulted a crepusculum upon the moon; but M. Schroeter has now converted this conjecture into a certainty by the observations contained in the present work. He has demonstrated not only that there is a crepusculum in the moon, but that we may measure the extent of it, as well as the thickness and density of the layers of the fluid which occasion it. The first complete observations were made by M. Schroeter upon this subject on the 24th of February, 1792, in the twilight of that night; the moon being then two days and a half old. With a Herschel telescope of seven feet, and magnifying seventy-four times only, he discovered in the obscure part of the moon some places illuminated with a dull greyish light, very near to other obscure parts which did not become visible until some time afterwards; a heavy and evidently crepuscular lustre enlightened the confines of the obscure edge of the planet, stretching into the points of its two horns, and this lustre spread out in the form of a pyramid, the summit of which was insensibly confounded with the light sent from the earth into the obscure part of the moon. The projection of this shining part was then 1′ 10″ in length, and 2″ in breadth.

He then concludes that this crepusculum of the moon can be better observed two or three days before and after the new moon, and in spring and autumn during the short crepuscula of the earth, and the greatest height of the moon in the horizon. Our author, therefore, fixed upon the moment of the smallest elongations of the moon, twenty-eight hours and a half after its being renewed, with a twenty-seven feet reflector. Hevelius had not been able to observe the moon until at least forty hours after the conjunction. By a geometrical process M. Schroeter estimated the extent of the lunar crepusculum, according to the distance comprehended between the limits of this crepusculum and the point of the horns, and he found by several observations that it extends over an arc of 2½ degrees of the moon's circumference. Or rather, taking the medium of twenty-two observations made during eight years, he estimates this extent more exactly at 2° 38′ 56″, but it sometimes amounted to 3° 6′ 44″. Several favourable circumstances must combine in order to observe this appearance. The author has sometimes perceived it merely in the prolongation of one of the two horns; at other times it was invisible, because apparently there were mountains which intercepted the light.

There remained a doubt whether this crepuscular light was or was not a consequence of the penumbra, or perhaps the effect of the immediate reflection of the solar rays, by means of some greyish plains in the moon. The author endeavours to resolve this doubt in a manner which sets at defiance the possibility of any illusion. Upon the whole, it is proper to say of this chapter upon the lunar atmosphere, that it contains the result of many years fatiguing observations, which will hand down the name of M. Schroeter as an honour to the age in which he lived.

If we adopt, in the calculation of these observations, the same principles by which La Hire has determined the height of our terrestrial atmosphere, by extending to 38,000 feet the height at which the atmosphere ceases to reflect the light in a sensible manner, or to 34,500, if the limit of refraction is in question, we find that the analogous limit in the atmosphere of the moon rises only 1,404 feet, according to the maximum of extent observed by M. Schroeter, namely, 3° 6′ 44″. But this height is solely that of the lunar crepusculum visible to us. The author estimates at 78 feet, the height of the strata of the lunar air which may occasion a crepusculum upon the same planet. From these data the author has theoretically enquired what ought to be the relative density of the atmosphere of the earth and of the moon, and he has found that the atmosphere of the latter ought to be twenty-nine times less dense than ours, and at the moment when the work was put to press, Dr. Melanderhielm, of Stockholm, wrote to M. Schroeter that he had ascertained that the density of the atmosphere of two planets should in general be as the square of the power of gravitation at their surface; now according to Newton, the gravity at the surface of the moon is to the same power upon the earth as 2,83 : 15,10, or as 1 to 5,33. According to this theorem, the density of the air of the moon should therefore be as the square of 5,33, or 28,40 times less than that of the air of the earth; this differs very little from the result incontestably found by M. Schroeter after a most fatiguing and intricate train of experiments.

According to the same principles, we ought to find the refraction at the surface of the moon to be 28 or 29 times less than at the surface of the earth.

M. Schroeter applies his discoveries upon the lunar atmosphere to the occultations of stars by this satellite. As the height of the inferior strata of the air, which can still break the rays of light in a manner sensible to us, does not exceed 648 yards, a quantity which viewed from the earth, only passes from the edge of the moon 0″ 36 of a second, the weakening of the light of a fixed star entering into this atmosphere could not, if it were sensible, be perceived except during a quarter of a second, the time which the moon takes to travel $\frac{36}{100}$ of a second of a degree in her orbit. Now the lustre of stars of the first, second, and third magnitude, is too strong to admit of our observing any diminution for so short a period. If it be a planet which undergoes the occultation, its diminution of light on arriving at the disk may proceed from the graduated occultation of its apparent diameter. This system agrees with twenty occultations described in detail by the author.

The most brilliant fixed stars, and the planets, exhibit no diminution of light in this case; it is only remarked from time to time in the minute stars, not visible to the naked eye, and these last only undergo this obscuring of their light, when by chance they come out or enter opposite to the summit of a mountain of mean altitude, when the air of the moon, less dense, cannot any longer cause any sensible refraction of the rays coming from the star. There may be exceptions when the star which enters corresponds to the declivity of a very high mountain; and entering also obliquely, it seems to lose its light gradually; a diminution which, according to the author's observations, in a certain case (the only one of the kind), may be remarked during seven or eight seconds. On this occasion, which furnishes a kind of micrometrical measurement applicable to the fixed stars, the author found their diameter very small. The diameter of Aldebaran, according to the time employed in its immersion upon the edge of the moon, appeared to him to be between $\frac{1}{8}$ and $\frac{1}{4}$ of a second; the diameter of the star 30, and the Pisces 33, appeared to be more than $\frac{1}{8}$ of a second. The other fixed stars suddenly disappeared, without the phenomenon having any sensible duration.

In the third chapter of the fourth section, M. Schroeter gives a kind of recapitulation. To this chapter an engraving is attached, which exhibits in a distinct manner the relation of the vertical height of the densest atmosphere of the moon, with the height of the mountains of that planet, which have been measured, and with the depth of the craters, and other cavities or hollows. In the first figure of this plate are represented the lowest chains of mountains, 16 or 18 yards high; on the second, the mountains with circular edges containing a plain or a crater; in the third, the higher mountains placed above some mountains with circular edges; in the fourth, the central mountains or those which are seen in the midst of craters of mountains, with circular edges; in the fifth, the other isolated mountains from 50 to 25,000 feet of vertical height, the craters and other cavities of the moon, from 602 to 50,80 yards in depth. All these particulars are represented upon the same scale on which 200 yards correspond to a decimal line. The same table contains comparisons between the highest mountains of the moon, and those of the earth, Venus, and Mercury; with the references between the altitudes of the crepuscular strata of the moon, the earth, and Venus. We see at a single glance, according to this table, that the craters and the fissures of the edges are for the most part proportionally deeper, according as the atmosphere is higher, and that consequently the air of the moon must attain a certain maximum of density in their interior; moreover that the accidental variations of the atmosphere cannot take place, except in the region of the lower mountains of the moon, and not at the summits of the high chains; these last being far above the densest strata. In fact, the author has most frequently observed these accidental variations in the lower regions; as, for instance, in the sea of the Crises, in Cleomedes Possidonius, Gassendi, &c. In this atmospherical constitution of trifling density, we ought not to be astonished if there be continually developed so many fermentable matters from the interior of the moon, and if we see no atmospherical productions like our clouds, and none of those regular easterly or westerly winds which we find upon our own earth, and upon Venus, Mars, and perhaps Saturn. The atmosphere of the moon seems in general to be too subtle for the existence of any winds which can be properly so called. Slight atmospherical vapours alone always cover some low and contracted plains, and in all cases those which constitute the inferior level of the moon.

Of the harvest-moon.—It is remarkable that the moon, during the week in which she is full about the time of harvest, rises sooner after sun-setting than she does in any other full-moon week in the year. By this means she affords an immediate supply of light after sun-set, which is very beneficial for the harvest and gathering in the fruits of the earth: and hence this full moon is distinguished from all the others in the year, by calling it the harvest-moon.

To conceive the reason of this phenomenon; it may first be considered, that the moon is always opposite to the sun when she is full; that she is full in the signs Pisces and Aries in our harvest months, those being the signs opposite to Virgo and Libra, the signs occupied by the sun about the same season; and because those parts of the ecliptic rise in a shorter space of time than others, as may easily be shewn and illustrated by the celestial globe: consequently, when the moon is about her full in harvest, she rises with less difference of time, or more immediately after sun-set, than when she is full at other seasons of the year.

In our winter, the moon is in Pisces and Aries about the time of her first quarter, when she rises about noon; but her rising is not then noticed, because the sun is above the horizon.

In spring, the moon is in Pisces and Aries about the time of her change; at which time, as she gives no light, and rises with the sun, her rising cannot be perceived.

In summer, the moon is in Pisces and Aries about the time of her last quarter; and then, as she is on the decrease, and rises not till midnight, her rising usually passes unobserved.

But in autumn, the moon is in Pisces and Aries at the time of her full, and rises soon after sun-set for several evenings successively; which makes her regular rising very conspicuous at that time of the year.

And this would always be the case, if the moon's orbit lay in the plane of the ecliptic. But as her orbit makes an angle of 5° 18′ with the ecliptic, and crosses it only in the two opposite points called the nodes, her rising when in Pisces and Aries will sometimes not differ above 1 h. 40 min. through the whole of seven days; and at other times, in the same two signs she will differ three hours and a half in the time of her rising in a week, according to the different positions of the nodes with respect to these signs; which positions are constantly changing, because the nodes go backward through the whole ecliptic in 18 years 225 days.

This revolution of the nodes will cause the harvest moons to go through a whole course of the most and least beneficial states, with respect to the harvest, every 19 years. The following table shews in what years the harvest-moons are least beneficial as to the times of their rising, and in what years they are most beneficial, from the year 1790 to 1861; the column of years under the letter L are those in which the harvest-moons are least of all beneficial, because they fall about the descending node; and those under the letter M are the most of all beneficial, because they fall about the ascending node.

Harvest Moons.

Acceleration of the Moon. See ACCELERATION.

Horizontal Moon.—It is a celebrated phenomenon that the moon appears larger in the horizon than in the meridian; whereas, from its being further from us in the former case than in the latter, it subtends a less angle when in the horizon. It is perhaps not easy to give a satisfactory answer to this deception. Gassendus thought, that as the moon was less bright in the horizon than in the meridian, we looked at it in the former situation, with a greater pupil of the eye, and therefore it appeared larger. But this is not agreeable to the principles of optics, since the magnitude of the image upon the retina of the eye does not depend upon the size of the pupil. Des Cartes thought that the moon appeared largest in the horizon, because when comparing its distance with the intermediate objects it appeared then furthest off; and as we judge its distance greater in that situation, we, of course, think it larger, supposing that it subtends the same angle. Dr. Berkeley accounts for it thus: faintness suggests the idea of greater distance; the moon appearing faintest in the horizon, suggests the idea of greater distance; and, supposing the angle the same, that must suggest the idea of a greater tangible object. He does not suppose the visible extension to be greater, but that the idea of a greater tangible extension is suggested, by the alteration of the visible extension. He says, 1. That which suggests the idea of greater magnitude, must be something perceived; for that which is not perceived can produce no effect. 2. It must be something which is variable, because the moon does not always appear of the same magnitude in the horizon. 3. It cannot lie in the intermediate objects, they remaining the same; also, when these objects are excluded from sight, it makes no alteration. 4. It cannot be the visible magnitude, because that is least in the horizon. The cause, therefore, must lie in the visible appearance, which proceeds from the greater paucity of rays coming to the eye, producing faintness. Mr. Rowning supposes, that the moon appears furthest from us in the horizon, because the portion of the sky which we see appears not an entire hemisphere, but only a portion of one; and hence, we judge the moon to be further from us in the horizon, and therefore larger. Dr. Smith, in his optics, gives the same reason. The same circumstances take place in the sun. Also, if we take two stars near each other in the horizon, and two other stars near the zenith at the same angular distance, the two former will appear at a much greater distance from each other than the two latter. On this account, people are, in general, much deceived in estimating the altitudes of the heavenly bodies above the horizon, judging them to be much greater than they are. The lower part of a rainbow also appears much wider than the upper part; and this may be considered as an argument that the phenomenon cannot depend entirely upon the greater degree of faintness of the object when in the horizon, because the lower part of the bow frequently appears brighter than the upper part, at the same time that it appears broader. Also, faintness can have no effect upon the angular distance of the stars; and as the difference of the apparent distance of the two stars, whose angular distance is the same in the horizon and the zenith, seems to be fully sufficient to account for the apparent variation of the moon's diameter in these situations, it may be doubtful whether the faintness of the object enters into any part of the cause.

MOON-BLINDNESS, a disorder in the eyes of a horse, so denominated from its having been thought to increase or decrease, according to the course of the moon.

This generally happens when a horse is turned five, coming six, at which time one eye becomes clouded, the eye-lids being swelled, and very often shut up; and a thin water generally runs from the diseased eye down the cheek, so sharp as sometimes to excoriate the skin. The veins of the temple, under the eye, and along the nose, are also turgid and full of blood, though sometimes it happens that the eye discharges but little.

Moon-blindness scarcely ever admits of a cure. It generally takes place while the horse is young, and sometimes has been attributed to the pain in cutting their teeth.

The inflammation in this disorder comes

and goes till the cataract is confirmed, and then all pain and running disappear, and the horse becomes totally blind, which is generally in about two years. During this time, some horses have more frequent returns than others, which continue in some a week, in others three or four, returning once in two or three months; and they are seldom so long as five without a relapse.

There is another kind of moon-blindness, which is also the forerunner of cataracts, where no weeping of the eye attends. The eye is here never shut up or closed, but will now and then look thick and troubled; at which time the horse sees nothing distinctly. When the eyes appear sunk and perishing, the cataracts are longer in forming, and it is not unusual in this case for one eye to escape.

MOON-EYED. See MOON-BLINDNESS.

MOON (Mountains of the), mountains of Africa, extending between Abyssinia and Monomotapa. They are higher than those of Atlas.

MOON-SEED. In botany. See MENISPERMUM.

MOON-STONE. In mineralogy. See FELSPATUM.

MOON-TREFOIL. In botany. See MEDICAGO.

MOON-WORT. In botany. See LUNARIA.

MOON-BEAM. *s.* (*moon* and *beam.*) Ray of lunar light (*Bacon*).

MOON-CALF. *s.* (*moon* and *calf*). 1. A monster; a false conception; supposed perhaps anciently to be produced by the influence of the moon (*Shakspeare*). 2. A dolt; a stupid fellow (*Dryden*).

MOON-EYED. *a.* (*moon* and *eye.*) 1. Having eyes affected by the revolutions of the moon. 2. Dim-eyed; purblind (*Ainsworth*).

MOON-FISH. *s.* *Moon-fish* is so called, because the tail fin is shaped like a half-moon (*Grew*).

MO'ONLESS. *a.* (from *moon.*) Not enlightened by the moon (*Dryden.*)

MO'ONLIGHT *s.* (*moon* and *light.*) The light afforded by the moon (*Hooker*).

MO'ONLIGHT. *a.* Illuminated by the moon (*Pope*).

MO'ONSHINE. *s.* (*moon* and *shine.*) 1. The lustre of the moon (*Shakspeare*). 2. (In burlesque.) A month (*Shakspeare*).

MO'ONSHINE. MO'ONSHINY. *a.* (*moon* and *shine.*) Illuminated by the moon.

MO'ONSTONE. *s.* A kind of stone (*Ainsworth*).

MO'ONSTRUCK. *a.* (*moon* and *struck.*) Lunatic; affected by the moon (*Milton*).

MO'ONY. *a.* (from *moon.*) Lunated; having a crescent for the standard resembling the moon (*Philips*).

MOOR. *s.* (*moer*, Dutch; *modder*, Teut. clay.) 1. A marsh; a fen; a bog; a tract of low and watery grounds (*Spenser*). 2. (*maurus*, Lat.) A negro; a black-a-moor.

To MOOR. *v. a.* (*morer*, French.) To fasten by anchors or otherwise (*Dryden*).

To MOOR. *v. n.* To be fixed by anchors; to be stationed (*Arbuthnot*).

To blow a MOOR. To sound the horn in triumph, and call in the whole company of hunters (*Ainsworth*).

MOOR-COCK. See TETRAO.

MOOR-HEN. See FULICA.

MOOR-TITLING. See MATACILLA.

MOOR'S-HEAD. In the manage: a term denoting the colour of a roan horse, who, besides the mixture or blending of a grey and a bay, has a black head, and black extremities, as the mane and tale.

MOOR LAND, or moory soil, in agriculture, is a black, light, and soft earth, very loose, and without any admixture of stones; and with very little clay or sand. The uppermost stratum of the fen lands is usually of this earth, and it commonly constitutes a moderately thick or deep bed. Intermixed with water it cannot easily be worked up into a paste; and when with labour worked up into somewhat of a firm mass its surface appears spongy and porous; and as soon as dry it easily moulders away to powder. It is usually soft to the touch, unless it be worked very closely between the fingers; then it shows a mixture of a small quantity of sand, both to the touch and to the eye. It seems indeed to consist almost entirely of pure vegetable matter; and this lying in such plenty on the surface of the fen-lands is the cause of their being so very fertile. The great disadvantage of the places which have this soil is their being liable to be glutted with wet; and to remedy the inconveniences arising from thence, the farmers who rent these lands have a custom of burning the soil at proper seasons. It burns very freely and easily, the surface readily catching flame; and a substance somewhat bituminous, usually contained among the soil, helps the burning.

MOORE (Sir Jonas), a very respectable mathematician, fellow of the Royal Society, and surveyor-general of the ordnance, was born at Whitby in Yorkshire about the year 1620. After enjoying the advantages of a liberal education, he bent his studies principally to the mathematics, to which he had always a strong inclination. In the expeditions of king Charles the First into the northern parts of England our author was introduced to him, as a person studious and learned in those sciences; when the king expressed much approbation of him, and promised him encouragement; which indeed laid the foundation of his fortune. He was afterwards appointed mathematical master to the king's second son James, to instruct him in arithmetic, geography, the use of the globes, &c. During Cromwell's government it seems he followed the profession of a public teacher of mathematics; for we find him styled, in the title-page of some of his publications, "professor of the mathematics." After the return of Charles the Second he found great favour and promotion, becoming at length surveyor-general of the king's ordnance. He was it seems a great favourite both with the king and the duke of York, who often consulted him, and were advised by him upon many occasions. And it must be owned that he often employed his interest with the court to the advancement of learning and the encouragement of merit. Thus, in conjunction with sir Christopher Wren, he got Flamsteed house built in 1675, as a public observatory, recommending Mr. Flamsteed to be the king's astronomer, to make the observations there: and being surveyor-general of the ordnance himself, that was the reason why the salary of the astronomer royal was made payable out of the office of ordnance. Being a governor of Christ's hospital, it seems that by his interest the king founded the mathematical school there, allowing a handsome salary for a master to instruct a certain number of the boys in mathematics and navigation, to qualify them for the sea service. It ought not to be concealed, that the duke of York also took a zealous and active part in determining his brother to found this useful establishment. This foundation presented sir Jonas with an opportunity of exerting his abilities in a manner agreeable to his wishes, namely, that of serving the rising generation. And reflecting within himself on the benefit which the nation might receive from a mathematical school if properly conducted, he made it his utmost care to promote its improvement. In pursuance of his majesty's grant, the school was established; but there was still wanting a methodical institution, from which the youths might receive such necessary helps as their studies required: a laborious work, from which his other great and assiduous employments might very well have exempted him, had not a predominant regard to a more general usefulness determined him to devote all the leisure hours of his declining years to the improvement of such an useful and important seminary of learning. Having thus engaged himself in the prosecution of this generous undertaking, he sketched out a plan or system of mathematics for the use of the school, and afterwards drew up and printed several parts of it himself; but death put an end to his labours, before the work was completed. We are not informed of the year when this event took place; but it could not be long before 1681, when the work was published by his sons-in-law, Mr. Hanway and Mr. Potinger, who spared neither expense nor labour to have it finished in the best manner, and securing proper assistants for that purpose. Besides the New System of the Mathematics, &c. in two volumes, quarto, above-mentioned, sir Jonas published, Arithmetic, in two books, viz. Vulgar Arithmetic, and Algebra. To which are added, two treatises, the one a new Contemplation Geometrical, upon the oval figure called the Ellipsis; the other, the two first Books of Mydorgius, his Conical Sections analyzed, 1660, octavo: A Mathematical Compendium; or, useful Practices in Arithmetic, Geometry, and Astronomy, Geography, and Navigation, &c. &c. the fourth edition of which is dated in 1705, 12mo.; A General Treatise of Artillery; or, Great Ordnance. Written in Italian by Thomas Moretii of Brescia. Translated into English, with Notes thereupon, and some Additions out of French for Sea-gunners. By sir Jonas Moore, knt. octavo, with the date of 1688.

Moore (Robert), an English penman and philologist, who succeeded John Ayres as a writing-master in St. Paul's Church-yard, which was about 1708. He published the Writing-master's Assistant; the General Penman, &c.

Moore, or **More** (Edward), a late ingenious writer, was bred a linen-draper, but quitted business to join the retinue of the Muses; and he certainly had a very happy and pleasing talent for poetry. In his Trial of Selim the Persian, he complimented lord Lyttelton in an elegant kind of panegyric, couched under the appearance of accusation: and his Fables for the female sex, for easy versification, poignant satire, and striking morals, approach nearer to the manner of Gay than any other of the numerous imitations of that author. He wrote also three dramatic pieces; the Gamester, a tragedy; the Foundling, and Gil Blas, comedies. The success of these was not such as they merited: the first of them having met with a cold reception, for no other apparent reason but because it too nearly touched a favourite and fashionable vice: and the second having been condemned for its supposed resemblance to sir R. Steele's Conscious Lovers, but to which good judges have been inclined to give it greatly the preference. Mr. Moore married a lady of the name of Hamilton, daughter to Mr. Hamilton, table-decker to the princesses; who had herself a very poetical turn, and has been said to have assisted him in the writing of his tragedy. One specimen of her poetry, however, was handed about before their marriage, and has since appeared in print in different collections of songs, particularly in one called the Goldfinch. It was addressed to a daughter of the famous Stephen Duck; and begins with the following stanza:

Would you think it, my Duck: (for the fault I must own),
Your Jenny at last is quite covetous grown:
Tho' millions if Fortune should lavishly pour,
I still should be wretched if I had not More.

And after half a dozen stanzas more, in which, with great ingenuity and delicacy, and yet in a manner that expresses a sincere affection, she has played upon our author's name, she concludes with the following lines:

You may wonder, my girl, who this dear one can be,
Whose merit can boast such a conquest as me:
But you shan't know his name, tho' I told you before,
It begins with an M, but I dare not say More.

In the year 1753 Mr. Moore commenced a weekly miscellaneous paper, intitled the World by Adam Fitz-Adam; in which undertaking he was assisted by lord Chesterfield with some essays. This paper was collected into volumes, and Mr. Moore died soon after.

Moore (Philip), rector of Kirk-bridge, and chaplain of Douglas in the Isle of Man, was the intimate friend of the apostolic Dr. Wilson, bishop of that see, whose funeral sermon he preached. He revised the translation of the Bible into the Manks language: and died universally beloved in 1783.

Moore (Dr. John), was born at Stirling in 1730, and educated for the medical profession. He remained for a considerable period at Glasgow; but when he had attained his fortieth year, an incident occurred that gave a new turn to his ideas, and opened new pursuits and situations to a mind naturally active and inquisitive. James George, duke of Hamilton, a young nobleman of great promise, being affected with a comsumptive disorder, in 1769, he was attended by Mr. Moore, who has always spoken of this youth in terms of the highest admiration; but as his malady baffled all the efforts of medicine, he yielded to his pressure, after a lingering illness, in the fifteenth year of his age. This event, which Mr. Moore recorded, together with the extraordinary endowments of his patient, on his tomb in the burying-place at Hamilton, led to a more intimate connection with this noble family. The late duke of Hamilton being, like his brother, of a sickly constitution, his mother, the duchess of Argyle, determined that he should travel in company with some gentleman, who to a knowledge of medicine added an acquaintance with the continent. Both these qualities were united in the person of Dr. Moore, who by this time had obtained the degree of M.D. from the university of Glasgow. They accordingly set out together, and they spent a period of no less than five years abroad, during which they visited France, Italy, Switzerland, and Germany. On their return, in 1778, Dr. Moore brought his family from Glasgow to London, and in the course of the next year appeared the fruits of his travels, in A View of Society and Manners in France, Switzerland, and Germany, in 2 vols. 8vo. Two years after, in 1781, he published a continuation of the same work, in two additional volumes, intitled, A View of Society and Manners in Italy. Having spent so large a portion of his time either in Scotland or on the continent, he could not expect suddenly to attain an extensive practice in the capital; perhaps, indeed, his travels and literary recreations rendered him averse from engaging in the hurry, bustle, and intrigue, incident to the profession of a London physician; he however was, till the time of his death, consulted by his particular friends. As if to prove, however, that he was neither unworthy, nor incapable of employment, in 1785 he published his Medical Sketches, a work, like all his other productions, favourably received; he is, however, supposed to have given some offence to a few narrow-minded men among his brethren, by the disclosure of certain *arcana* which they wish for the sake of their interest to conceal, and therefore consider it as high treason for any one to reveal. The next of our author's works which we shall mention is his Zeluco. This performance abounds with many interesting events, but its chief tendency is directed towards the education of youth, as it fully evinces the fatal effects resulting from uncontrouled passion on the part of a darling son, and unconditional compliance on that of a fond mother. While drawing the character of his hero, the author considers himself employed in "tracing the windings of vice, and delineating the disgusting features of villany." This story is calculated rather to affect the reader with horror, than warn him by example; it abounds, however, with incident, but it is to be hoped that a character so atrocious as that of Zeluco never existed in life, and is only to be met with in the pages of a novel. A great and important event, no less than that of the French revolution, now occupied the minds and writings of the literary world. Dr. Moore, instead of surveying it at a distance, like the bulk of mankind, was lucky enough to contemplate a most critical portion of it on the spot. After his return to England in 1793 he began to arrange his materials, and in 1795 published A View of the Causes and Progress of the French Revolution, in 2 volumes, 8vo. dedicated to the duke of Devonshire. He begins with the reign of Henry IV. and ends with the execution of the royal family. In 1796 appeared Edward: various Views of Human Nature, taken from Life and Manners chiefly in England. In 1800, Dr. Moore published his Mordaunt, being Sketches of Life, Characters, and Manners in various Countries, including the Memoirs of a French Lady of Quality, in 2 volumes, 8vo. This chiefly consists of a series of letters written by the hon. John Mordaunt, while confined to his couch at Vevay, in Switzerland, giving an account of what he had seen in Italy, Germany, France, Portugal, &c. The work itself comes under no precise head, being neither a romance, nor a novel, nor travels: the most proper title would perhaps be that of Recollections. Dr. Moore died at Richmond, early in the year 1802.

MOORING, the act of confining and securing a ship in a particular station, by chains or cables, which are either fastened to the adjacent shore, or to anchors in the bottom. A ship may be either moored by the head, or by the head and stern: that is to say, she may be secured by anchors before her, without any behind: or she may have anchors out, both before and behind her; or her cables may be attached to posts, rings, or moorings, which answer the same purpose.

Moorings, in sea-language, are usually an assemblage of anchors, chains, and bridles, laid athwart the bottom of a river or haven to ride the shipping contained therein. The anchors employed on this occasion have rarely more than one fluke, which is sunk in the water near low-water mark. Two anchors being fixed in this manner in the opposite side of the river, are furnished with a chain extending across from one to the other. In the middle of the chain is a large square link, whose lower end terminates in a swivel, which turns round in the chain as about an axis, whenever the ship veers about with the change of the tide. To this swivel-link are attached the bridles, which are short pieces of cable well served, whose upper ends are drawn into the ship at the mooring-ports, and afterwards fastened to the masts or cable-bolts. A great number of moorings of this sort are fixed in the harbours adjacent to the king's dock-yards, as Deptford, Chatham, Portsmouth, Plymouth, &c.

MO'ORISH. Moory. *a.* (from *moor.*) Fenny; marshy; watery (*Hale*).

MOORS. See Morocco.

Moors, in the Isle of Man, officers like the bailiffs of hundreds in England.

MOORSHEDABAD, a city of Hindoostan Proper, the capital of Bengal before the establishment of the English power. It is seated on the western arm of the Ganges, 120 miles N. of Calcutta. Lon. 88. 28 E. lat. 24. 15 N.

MOOSE, in mastiology. See Cervus.

MOOT, formed either from the Saxon *metan, gemetan*, meeting; or from the French *mot*, word, a difficult case, or question, argued by the students of inns of court, by way of exercise.

MOOTER, in the dock-yards, the person who forms and smooths the tree-nails for use.

MOOTING, the chief exercise of the students in the inns of court; being the arguing of cases, which young utter barristers, &c. perform at appointed times, the better to enable them for practice, and the defence of their clients causes.

Such as, from their learning and standing, are called by the benchers to argue moot-cases, are sometimes called utter barristers; the rest, who, for want of experience, &c. are not admitted, are by some called inner barristers. The place where the moot-cases were argued was anciently called a moot-hall.

In the inns of court there is a bailiff or surveyor of the moots, yearly chosen by the bench to appoint the moot-men for the inns of chancery, and to keep account of performance of exercises, both there and in the house.

MOOT-MEN, are those who argue moot-cases.

Out of these moot-men are chosen readers for the inns of chancery; where, in term-time, and in vacations, they argue cases in the presence of attorneys and clerks.

MOP. *s.* (*moppa*, Welsh.) 1. Pieces of cloth, or locks of wool, fixed to a long handle, with which maids clean the floors (*Swift*). 2. A wry mouth made in contempt (*Shakspeare*).

To Mop. *v. a.* (from the noun.) To rub with a mop.

To Mop. *v. n.* (from *mock.*) To make wry mouths in contempt (*Shakspeare*).

To MOPE. *v. n.* To be stupid; to drowse; to be in a constant day-dream (*Rowe*).

To Mope. *v. a.* To make spiritless; to deprive of natural powers (*Locke*).

Mope-eyed. *a.* Blind of one eye (*Ainsworth*).

MO'PPET. Mo'psey. *s.* A puppet made of rags, as a mop is made; a fondling name for a girl (*Dryden*).

MOPSOPIA, an ancient name of Athens, from Mopsus, one of its kings.

MOPSUS, a celebrated prophet, son of Manto and Apollo during the Trojan war. A jealousy subsisted between Mopsus and Calchar, the soothsayer, respecting their skill in divination. A trial was then agreed upon, in which the inferiority of the prophetic knowledge was fully manifested. Calchas confessed his ignorance, and died by excess of grief which his defeat produced; and Mopsus, after death, was ranked among the gods.—2. Another prophet, a son of Ampyx and Chloris, born at Titaressa in Thessaly. He was the prophet and soothsayer of the Argonauts, and died at his return from Colchis by the bite of a serpent in Libya.

MORABIN (James), a learned Frenchman, who died at Paris in 1762. He published a life of Cicero, and translated some of that writer's works, also those of Boetius.

MORÆA, in botany, a genus of the class triandria, order monogynia. Corol six-petalled; the three inner petals expanding, narrower; stigma three-cleft. Seventeen species, for the most part Cape plants, herbaceous, with bulbous, tuberous roots, and flowers resembling the iris. Most of them contribute largely to the beauty of a green-house, and may be propagated in or about August by offsets, parted, roots or seeds. See Botany, Pl. cxxxviii.

MORAI, the name given at Otaheite in the South Sea to the burial-grounds which are also places of worship.

MO'RAL. *a.* (*moral*, Fr. *moralis*, Latin.) 1. Relating to the practice of men toward each other, as it may be virtuous or criminal, good or bad (*Hooker*). 2. Reasoning or instructing with regard to vice and virtue (*Shakspeare*). 3. Popular; such as is known or admitted in the general business of life (*Tillotson*).

Mo'ral. *s.* 1. Morality; practice or doctrine of the duties of life (*Prior*). 2. The doctrine inculcated by a fiction; the accommodation of a fable to form the morals (*Swift*).

To Mo'ral. *v. n.* (from the adjective.) To moralize: not in use (*Shakspeare*).

Moral philosophy has been defined the science of manners or duty; which it traces from man's nature and condition, and shews to terminate in his happiness.

Various writers, both ancient and modern, have treated this interesting subject: the systems of moral philosophy most prized among the moderns, are that in Dodsley's Preceptor (which has been inserted in many of our Encyclopædias), that by Mr. Grove, and the one by the late venerable Dr. Paley. This latter mentioned system is open to some strong objections, on account of its author's leaning too much on the principle of expediency: yet it is on many accounts highly valuable. We therefore, instead of presenting any crude remarks on a subject which requires much time to reduce into a comprehensive and satisfactory system, shall lay before our readers Mr. Legrice's copious analysis of the work of Dr. Paley.

Moral philosophy

Is the science which teaches men their duty, and the reasons of it. B. 1. c. 1.

The rules of life may be deficient, or ill applied.

These rules are the law—of honour—of the land—of scripture.

The first being constructed by people of fashion to facilitate their intercourse with one another, favours whatever indulgence of the passions does not interrupt that intercourse. B. 1. c. 2.

It regulates the duties only betwixt equals.

Omits those to the Supreme Being, and inferiors.

The second omits duties which are not objects of compulsion. B. 1. c. 3. s. 1.

Permits to go unpunished crimes which cannot be defined. S. 2.

If otherwise, it would be inconsistent with freedom.

The third contains general rules of piety. B. 1. c. 4.

Particular instances useless, because innumerable.

It presupposes a knowledge of natural justice.

The object of the scriptures is to enforce practice by new sanctions, and a greater certainty.

Hence they do not supersede the use of this science, nor, their end being considered, are they imperfect.

Moral sense. B. 1. c. 5.

Whether it exists cannot be found by experiment.

Arguments for its existence.

1st. We approve or disapprove certain actions without deliberation.

2d. This approbation or disapprobation is uniform and universal.

Against it. 1st. This uniformity of sentiment does not pervade all nations.

2d. Approbation of particular conduct arises from a sense of its advantages.

The idea continues when the motive no longer exists.

Receives strength from authority, imitation, &c.

The efficacy of imitation is most observable in children.

3d. There are no maxims universally true, but bend to circumstances.

4th. There can be no idea without an object, and instinct is inseparable from the idea of the object.

No dependence on the moral sense in reasoning, because scarce distinguishable from prejudice and habit.

Could carry with it no authority, because every man would be his own judge.

Human happiness.

Happy is a relative term. B. 1. c.

Happiness does not consist in

1st. Pleasures of sense,

Because they are of short duration at the time;

Because they cloy by repetition;

Because eagerness for intense delights takes away relish for others.

These objections are valid independent of loss of health, &c.

2d. In exemption from evils which are without, as labour, &c.

Because the mind must be employed.

Hence pain is sometimes a relief to the uneasiness of vacuity.

3d. In greatness, or elevated station,

Because the highest in rank are not happiest, and so in proportion.

Because superiority, where there is no competition, is seldom contemplated.

Happiness is to be judged of by the apparent happiness of mankind, which consists in

1st. The exercise of the social affections,

2d. The exercise of the faculties of body or mind for an engaging end,

Because there is no happiness without something to hope for.

Those pleasures are most valuable which are most productive of engagement in the pursuit.

Therefore endeavours after happiness in a future state produce greatest happiness in this world.

3d. In a prudent constitution of habits.

Habits of themselves are much the same, because what is habitual becomes nearly indifferent;

Therefore those habits are best, which allow of indulgence in the deviation from them.

Hence that should not be chosen as a habit, which ought to be a refreshment.

Hence by a perpetual change the stock of happiness is soon exhausted.

4th. In health,

Because necessary for the enjoyment of every pleasure.

Because itself is a pleasure, perhaps the sole happiness of some animals.

From the above account follow two conclusions.

1st. Happiness appears to be pretty equally distributed.

2d. Vice has no advantage over virtue with respect to this world's happiness.

Virtue

"Is the doing good to mankind, in obedience to "the will of God, and for the sake of everlasting "happiness." B. 1. c. 7.

It may be divided into duties towards God, towards others, and towards ourselves.

General observations.

1st. Mankind act more from habit than reflection. B. 1. c. 7.

We know it from experience.

This mode of acting best suits the exigencies of life.

Therefore virtue consists in forming proper habits.

Hence whatever tends to a good habit is to be done for that reason, and *vice versa.*

2d. The Christian religion has not ascertained the precise quantity of virtue necessary to salvation,

Because impossible to be expressed or limited;

Hence rewards and punishments will be in proportion to our deeds.

These general positions may be advanced:

1st. A state of happiness cannot be expected by those who are conscious of no moral or religious rule.

Because, if so, religion, both natural and moral, would be useless.

2d. By those who reserve to themselves the practice of any particular sin.

Because all commands stand alike on the authority of God.

Because such allowance would tolerate every vice.

Because scripture excludes such hope.

3d. A state of unprofitableness will be punished;

Because so laid down in scripture.

4th. Where a question of conduct is doubtful, we are bound to take the safe side,

Because whatsoever is not of faith is sin.

Moral obligation.

Moralists all coincide in prescribing the same rules of conduct, but differ in the reasons why we are obliged to pursue such conduct. B. 2. c. 1.

A man is obliged when he is urged by a violent motive resulting from the command of another. B. 2. c. 2.

Why am I obliged to keep my word? B. 2. c. 3.

Because urged by a violent motive (fear of punishment after death) resulting from command of another (God.)

N. B. Punishments after death taken for granted. B. 2. c. 3. s. 2.

To inquire what is our duty is to inquire what is the will of God. B 2. c. 4.

Which may be found,

1st. By his express declaration in scripture.

2d. By the light of nature.

By which inquiring into the tendency of an action to promote or diminish the general happiness, we find the will of God. B. 2. c. 4.

N. B. Actions are to be considered here in the abstract. Note, c. 6.

The Divine Benevolence.

God wishes the happiness of man. B. 2. c. 5.

For he did not wish man's misery;

Because he might have made every object offensive, which he has not.

He was not indifferent about it;

Because, if so, all things came by chance.

The world is full of contrivances, which shew design.

These contrivances for beneficial purposes;

Liable to evil, but not constructed for that purpose.

Utility.

Whatever is expedient is right. B. 2. c. 6.

The utility of a moral rule constitutes the obligation of it.

This is to be judged of by general rules. B. 2. c. 7.

Because actions are expedient or not according to their general consequences. B. 2. c. 8.

Of Right.

Right and obligation are reciprocal. B. 2. c. 9.

Therefore right signifies "consistent with the will of God." C. 9. and 4.

Right is a quality of persons or of actions. C. 9.

Rights of persons are natural or adventitious. alienable, or unalienable, perfect, or imperfect, C. 10.

Natural rights would belong to a man, although no civil government subsisted, as right to life, &c.

Adventitious would not, as right of a general over his soldiers, &c.

Some rights are alienable, as of property, &c. C. 10. s. 2.

Some unalienable, as of husband over wife, &c.

Rights are perfect, which may be asserted by force, as right to life, &c. C. 10. s. 3.

Imperfect may not, as right of a benefactor to gratitude, &c.

Because indeterminate.

Therefore to assert them by force is inconsistent with the general happiness, that is the will of God. B. 2. c. 4.

Imperfection of a right refers only to force in assertion, not at all to the obligation of a right.

General rights of mankind are those, which belong to the species collectively. B. 2. c. 11.

These are,

1. A right to the fruits of the earth. S. 1.

Because provided for us by God.

2. A right to the flesh of animals. S. 2.

Because given by authority of God for support of life.

Therefore all waste or misapplication of them a sin.

Hence nothing should be exclusive property, which can conveniently be common, and *vice versa.*

The right of extreme necessity. S. 3.

As a right to use or destroy another's property, if necessary to our preservation.

Because division of property was not instituted to operate to the destruction of any.

Institution of property. B. 3. c. 2.

Advantages of it.

Increases the produce of the earth. S. 1.

Preserves it to maturity. S. 2.

Prevents contests. S. 3.

Improves conveniency of living. S. 4.

Right of property in land

Not founded on the tacit consent of mankind. B. 3. c. 4.

Because silence is not consent where a person knew nothing about the matter.

Not founded on labour being mixed with it;

Because this is just, only when the value of the labour is proportional to the value of the thing, or where the thing derives its value from the labour.

This plea will not give right in perpetuity;

Nor will it hold in taking possession of a tract of land as a navigator.

The first right of ownership arises from the natural right of man to appropriate to his own use what he stands in need of. B. 2. c. 10. s. 1.— B. 3. c. 4.

This will justify property only as far as a provision for natural exigencies.

The real foundation of our right is the "law of the land." B. 3. c. 4.

Property is established by the will of God. B. 3. c. 2.

Land cannot be divided into property without the regulation of the law of the land. B. 3. c. 4.

Therefore so to regulate it is "consistent with the will of God."

Hence right to property in land does not depend on the manner of the original acquisition, or on the expediency of the law.

Of these principles a bad use may be made.

But he is guilty in *foro conscientiæ,* who abides not by the spirit of the law.

N. B. Property may be regarded as the principal subject of the determinate relative duties.

Promises. B. 3. c. 5.

The obligation of them arises from the necessity of it to the well-being and existence of society. S. 1.

They are to be interpreted in the sense in which the promiser was conscious the promisee received them. S. 2.

Because in any other sense they would be equivocal.

Hence the obligation depends on the expectations excited.

Therefore tacit promises are binding.

Promises are not binding,

1st. Where the performance is impossible. S. 3.

If the promiser knows this at the time of promise, he raises an expectation which he knows he cannot gratify, that is, breaks a promise.

2d. Where the performance is unlawful;

Because the promiser was under a prior obligation to the contrary.

This holds whether the unlawfulness was known to the parties at the time of the promise, or not.

The reward of a sin, when committed, ought to be paid:

Because performance of the promise does not increase the sin.

A promise is binding, if it be lawful, when demanded, though it were not so at the time of promising.

A promise is not unlawful, when it produces no effect beyond what would have taken place had the promise never been made;

Because the public lose nothing by the promise, when they could have gained nothing without it.

3d. Where they contradict a former promise;

Because the performance is then unlawful.

4th. Before acceptance;

Because no expectation has been voluntarily excited.

5th. Which are released by promisee.

6th. In certain cases, where they are erroneous.

7th. Which were made in fear;

Because the general consequences would be hurtful to mankind.

Vows are under the same laws as promises.

Although the violation of them shews want of reverence to the Supreme Being; the performance of them, where they become unlawful, shews greater.

A contract is a mutual promise. B. 3. c. 6.

Therefore is to be interpreted in the same manner.

Contracts of sale. C. 7.

The seller is bound to discover the faults of what he sells;

Because the buyer did not expect them. C. 6.

Passing bad money is an article of this kind.

The tradesman is bound to sell at market price;

Because so expected by the buyer. C. 6.

Innumerable cases must be determined by custom;

Because the contracting parties tacitly include the rules of custom as conditions of sale.

Contracts of hazard.

No advantage is to be taken on either side, which was not expected by the other. C. 6.

Contracts of lending of property,

Which is divided into inconsumable (i. e. where the thing lent is itself to be returned), and consumable (i. e. which can be returned only in kind), as corn, money, &c.

If the thing lent be lost or damaged, who is to bear the loss?

Where the owner foresees the risk, he undertakes it;

Because an implied condition of the contract. B. 3. c. 6.

If an estate, during a lease, be altered in its value, the hirer takes the consequences only of those alterations which might be expected by the parties. C. 6.

*Contracts concerning the lending of money. B. 3. c.*10.

The prohibition in scripture against usury was meant only for the Jews.

Usury, that is, interest according to the will of the lender, is agreeable to natural equity.

It is necessary that it should be under regulations, as by that means it will contribute to general happiness;

Because it checks the accumulation of wealth without industry.

Because it enables men to adventure in trade.

Because it enables the state to borrow.

Money borrowed in one country and paid in another is to be paid so that the lender is not the sufferer. C. 6.

So if the value of coin be altered,

A man is bound to pay money, when any lawful method is in his power;

Because on this security credit was given. B. 3. c. 6.

Imprisonment of insolvent debtors is just, being a public punishment for a crime. B. 3. c. 10. B. 2. c. 8.

Properly put in the power of the creditor, because he is most likely to be vigilant, and because it adds to his security.

It is unjust in the creditor to imprison an unfortunate debtor;

Because he punishes where there is no crime according to the spirit of the law.

Contracts of service. B. 3. *c.* 11.

The master's authority extends no farther than the terms of the contract will justify.

Contracts of service are subject to the same laws as promises are.

Rules of custom are tacit conditions of the contract.

The master is responsible for every thing done by a servant under the general authority committed to him.

Because people act with the servant under this expectation.

To give a bad servant a good character is criminal.

The reverse of this is equally, if not more criminal.

A master is obliged to check vice in his domestics;

Because he has authority, which he is ordered by scripture to use for that purpose.

Contracts of labour.

Commissions. B. 3. *c.* 12.

Whoever undertakes another's business, promises to employ the same care upon it as if it were his own, and no more.

These cases are subject to the same laws as promises are. Vid. b. 3. c. 5.

Partnership. C. 13.

Binding in the same respects as all contracts, that is, promises.

Division of stock must depend on custom or agreement.

According to natural equity the profits should be divided between the labouring partner, and him who provides money, in the proportion of interest of money to the wages of labour.

Offices. C. 14.

In offices, as fellowships of colleges, &c. a man performs his duty who performs what his electors expected of him.

Because this was the expectation on both sides at the time of contract.

An office may not be discharged by a deputy,

1st. Where confidence is reposed in the particular abilities of the person elected.

2d. Where the custom hinders.

3d. Where the duty from its nature cannot be so well performed by a deputy.

4th. Where to employ deputies from general consequences would be bad, as in the army.

Non-residence of parochial clergy does not fall under these heads.

Revenues of the church are a common fund for the support of the national religion.

So to be judged of in its distribution.

Lies. C. 15.

A lie is a breach of promise; because in discourse there is a tacit promise to speak the truth.

The general consequences of lying are bad:

Because confidence is necessary to the intercourse of society.

Hence "white lies" are not entirely innocent.

(They habitually lead to others of a darker complexion.)

Hence too *pious* frauds, though meant to do good, are highly injurious to the cause of religion.

There are falsehoods which are not lies, and therefore not criminal.

1st. Where no one is deceived, as in novels, &c.

2d. Where no inconvenience results from the want of confidence in such cases, as where you tell a falsehood to a madman, a robber, &c.

Upon this principle we may deceive an enemy by feints, spies, &c. in war.

But by no means in treaties, truces, &c.

Any wilful deceit is a lie.

A man may *act* a lie.

There are lies of omission, as where you conceal part of the truth.

Oaths. C. 16.

Forms of oaths vary in different countries. S. 1.

The signification is the same, viz. the calling of God to witness. S. 2.

Our Saviour's words concerning oaths relate not to judicial, but wanton oaths. S. 3.

Oaths receive their obligations from a belief that God will punish perjury, which we have reason to think he will. S. 4.

1. Because the perjurer implies a disbelief of God's power, or contempt of it.

2. Because perjury violates a superior confidence, and therefore it is hurtful in its general consequences.

Hence a quaker's word, if broken, incurs the guilt of perjury.

Promissory oaths are not binding where the promise would not be. Vide B. 3. c. 5.

An oath is designed for the security of the imposer, therefore it is just "*jurare in animum imponentis.*"

Oath in evidence. C. 17.

The witness swears to speak the whole truth.

Therefore to conceal part is perjury.

This oath is not binding in some cases according to the law of the land, that is, *animus imponentis.*

Oath of allegiance. C. 18.

Ascertains not the extent of the subject's obedience, but the person to whom it is due.

The oath excludes

1. All intention to support the claim of another.

2. All design, at the time, of deposing the reigning prince.

3. All opposition from private views.

It permits

1. Resistance to the king, if beneficial to the community.

2. Disobedience to unlawful commands.

3. Does not require allegiance after he is deposed.

Oath against simony. C. 20.

Was meant to restrain the patron of a piece of preferment from being influenced in his choice of a presentee by a bribe or any benefit to himself.

The law determines what is simoniacal contract.

1st. Purchasing a benefice already vacant.

2d. A clergyman purchasing the next turn of a benefice for himself directly or indirectly.

3d. The procuring of any preferment by ceding to the patron any right or portion of profit.

4th. A bond to resign upon demand.

Oath to observe local statutes. C. 21.

The *animus imponentis*, that is, the measure of the juror's duty, seems to be satisfied, when nothing is omitted, but what from change of circumstances the founder, it may be presumed, would have dispensed with.

To come within this rule, the inconveniency must be manifest by being unlawful, impracticable, or prejudicial to the end of the institution.

Subscription to articles of religion. C. 22.

The subscriber's assent is governed by the same rule of interpretation as oaths are, that is, the *animus imponentis.*

The imposer, whose intention is to be satisfied, is the legislature of the 13th Eliz.

It is impossible that the legislature could expect the assent of ten thousand men, and that in perpetual succession, to many hundreds of controverted propositions.

The intention was to exclude from offices in the church,

1. All abettors of popery.

2. Baptists, at that time a powerful party on the continent.

3. The Puritans, who were hostile to an episcopal constitution.

4. In general the members of such leading sects, or foreign establishments as threatened to overthrow our own.

Some limitations of the patrons choice may be necessary to prevent unedifying contentions between neighbouring teachers, or between the teachers and their congregations.

This danger, if it exist, might be obviated by converting the articles of faith into articles of peace.

Wills. C. 23.

The disposal by will of the produce of personal labour is a natural right;

Because there is no limit to the continuance of the right.

With respect to other property, as of land, the right is adventitious;

1. Because at the death of the possessor his want of it ceases. Vide, B. 3. c. 4.

2. Because if a man possesses any right of disposal, he possesses a right of disposal for ever, which is absurd.

Therefore this right is received from, and is to be regulated by, the law of the land.

Hence, if informal, the will is not binding;

Because the conditions, upon which the right was obtained, were not complied with.

Succession to intestates must be regulated by the law of the land.

There are many *imperfect duties* in respect to the making and observing of wills. Vide, B. 1. c. 3. s. 1.

Such as respect the intention of the deceased,

Impartial love of children, &c.

Provision for poor relatives.

Charity. B. 3. *c.* 1. *p.* 2.

Is the promoting of the happiness of our inferiors, of doing which there are three principal methods:

First method. By tender treatment of our domestics and dependents. C. 2.

It is our interest; for they will shew their gratitude by being serviceable, and our obligation to them is much greater than theirs to us.

It is our duty; because we are forbid to diminish the sum of human happiness.

All uneasiness therefore, which we occasion without a just cause, is wrong.

The same is applicable to slaves;

Because founded on a principle independent of the contract of service.

Slavery. C. 3.

Is an obligation to labour for another without consent of the servant.

This may arise from crimes, captivity, or debt.

The continuance ought to be in proportion to the crime.

The slave trade can be excused by none of these principles.

The necessity pleaded for it is ridiculous.

The Christian scriptures interfere with no civil institution, and therefore not with slavery.

If they had, a *bellum servile* might have ensued.

This does not argue against a gradual emancipation.

2d method. By professional assistance. B. 2. c. 4.

This kind of beneficence is chiefly to be expected from members of the legislature, magistrates, legal and sacerdotal professions.

Because the law cannot provide for the poor in these cases, and the rich can take care of themselves.

Every professional man has it in his power to do the greatest good at the least expence.

3d method. By pecuniary bounty. C. 5.

We are obliged to bestow relief on the poor. S. 1.

(The impulse we feel indicates the divine intention.)

1. Because property was divided that all might have a sufficiency. Vide B. 2. c. 4.

2. Because the scripture enjoins us to bestow relief.

The manner of bestowing it. S. 2.

It is better to give a considerable sum among few, than the same sum among many.

To give to public charities is eminently useful, because in them money goes farther.

Indiscriminate relief to beggars is not to be encouraged.

That charity is most useful which promotes industry.

Charity is not to be kept secret, if by being published it may be useful in influencing others.

Few excuses for not giving relief are just. S. 3.

Resentment,

May be distinguished into anger and revenge. B. 3. c. 6. p. 2.

Anger is involuntary in some degree. C. 7.

Therefore, if checked, is no crime.

Is sinful, if it is suffered to continue long.

This is the doctrine of scripture.

Reflections, which may appease it, are numerous.

Revenge, C. 8.

Is the infliction of pain on another, in consequence of an injury received from him, farther than the just ends of reparation or punishment require.

Is forbidden by scripture, which forbids the neglect even of imperfect duties towards an enemy.

At the same time the punishment of public offenders is permitted,

Because necessary to public happiness.

So, if it be from a good motive, correction of vice is proper in individuals.

It is productive of good.

Witness the seclusion of bad women from the company of women of character.

Duelling, C. 9.

As a punishment absurd,

Because the person offended may be the sufferer.

So also as a reparation,

Because it does not undo the injury.

It is complied with for the sake of fashion.

Regard for reputation will not justify murder.

In expostulating with the duellist, we have a right to suppose his adversary to fall,

Because if he has no right to kill, he has no right to attempt it.

Where the injury is forgiven, and both parties fight for reputation's sake, there is no distinction between the guilt of him who accepts, and him who gives the challenge.

The law on this head is insufficient;

But opinion cannot be controlled by civil institutions;

Therefore a court of honour or something similar seems the only remedy.

Litigation, C. 10. *p.* 2.

Is not inconsistent with any rule of the gospel, when it is instituted with a view to the public good, or with a view to the ends of justice and safety.

It becomes unjust when instituted from any other motive, and when it is carried on in any manner that does not most readily promote these ends.

It is our duty to bring an offender to punishment, when it is conducive to the public good.

Gratitude, C. 11.

Is a duty, because the violation of it would be pernicious in its general consequences;

Because the love of God cannot exist without it.

It does not supersede other duties.

Slander, C. 12.

Slander is the producing of gratuitous mischief.

Speaking is acting, if the mischief and motive are the same.

Truth may be instrumental to the success of malice.

If the end is bad so are the means.

The guilt must be measured by the misery produced.

The guilt of inconsiderate slander consists in want of regard to the general consequences

Therefore shews want of just affection for human happiness.

Of relative duties, which result from the constitution of the sexes. B. 3. p. 3.

The constitution of the sexes is the foundation of marriage.

Collateral to the subject are fornication, seduction, adultery, incest, polygamy, divorce.

Consequential to it are the reciprocal duties of parent and child.

Use of marriage institutions. C. 1.

They promote

1st. The private comfort of individuals, especially of females.

Whatever promotes the happiness of the majority, is binding upon the whole.

2d. The better production of children, and provision for them.

3d. The peace of society.

4th. The better government of society. S. 4. and 5.

5th. The encouragement of industry.

Fornication. C. 2.

The guilt of it consists in,

1st. Its tendency to diminish the number of marriages.

2d. Encouragement of prostitution and its miseries.

3d. Encouragement of habits of lewdness.

Consequently it incurs the guilt of the general consequences of lewdness.

4th. The perpetuation of a loathsome disease.

It is expressly forbid by Scripture.

Licensed brothels vitiate the public opinion.

The keeping of a mistress is not the same as marriage, because not so beneficial to the woman and her children.

Is a crime,

1st. Because it is fornication.

2d. Because it is pernicious in its general consequences. B. 2. c. 8.

Seduction. C. 3.

Is a fraud of which the injury is threefold.

1st. To the woman, who suffers the pain of shame and sustains the loss of her reputation, and generally of her moral principle.

The evils arising to the woman in consequence are great, and the seducer incurs the guilt of them.

2d. To the family.

3d. To the public, who lose a valuable member of society.

Adultery. C. 4.

Where the man solicits the chastity of the woman, he incurs the guilt of seduction in every respect.

The crime of both parties is aggravated by the extreme misery brought upon the husband, and children.

The guilt is independent of discovery, because such conduct is pernicious in its general consequences;

And is a breach of the marriage vow before God.

Prior transgression of either party is no justification;

Because the marriage vow does not depend on reciprocal fidelity.

The Scripture makes a difference between fornication and adultery.

Christ's opinion of the magnitude of the sin cannot be inferred from his words to the adulterous woman.

He told her, she had "sinned."

Incest. C. 5.

Should be kept in utter abhorrence to preserve chastity in families.

Restrictions extending to remove degrees of kindred are founded on positive laws,

Which are justifiable because beneficial in their general consequences, in diffusing wealth, &c.

Polygamy. C. 6.

May be judged to be against the will of God,

Because he has created very nearly equal numbers of each sex,

And because it is hurtful in its general consequences.

For 1st. It distracts the affections.

2d. It dissolves the vigour of the faculties.

3d. It debases half the creation.

4th. It provides less for the children.

It produces no benefit in population.

The words of Christ, "whosoever putteth away his wife, and marrieth another, committeth adultery," imply a prohibition of it.

It is retained only where Christianity is not professed.

Divorce. C. 7.

By divorce is meant the dissolution of the marriage contract at the will of the husband.

If it be by mutual consent, it is equally liable to objection.

Except on account of the duties, which parents owe to their children, there is no reason in nature why marriage should not be dissoluble like other contracts.

General consequences require that it should be indissoluble.

1. Because it tends to preserve concord between the parties.

2d. Because new objects of desire would continually be sought after, if men could at will be released from the matrimonial tie.

The law of nature admits of an exception in favour of the injured party in cases of adultery, desertion, &c.

By no means in case of peevishness, &c. though not trivial reasons; because the unhappiness of one pair must be sacrificed to general consequences.

The Scripture allows divorce only in cases of adultery. So does the law of the land.

Inferior causes may justify the separation of the parties, if the care of the children does not require that they should live together;

In cases of tyranny in the husband the law provides a divorce *a mensa et thoro*;

In these cases the marriage is not dissolved, because the general consequences would be hurtful.

Sentences, which release the parties *a vinculo matrimonii*, do not dissolve a marriage; but declare that it never existed.

Marriage, C. 8.

Is a religious ceremony from custom only.

Which part should give the dowry has been settled by fashion.

As it is at present, it secures to women that assiduity and respect, which are wanted to compensate for the inferiority of their strength.

What duties the vow creates are expressed in the ceremony.

It is witnessed before God; therefore, if broken, incurs the greatest guilt of a violated oath.

Obedience on the part of the wife is ordered, because it is necessary that one party should submit.

He may conscientiously marry, who wishes and expects to entertain an affection for his wife.

The marriage vow is violated,

1st. By adultery.

2d. By behaviour, which knowingly renders the life of the other miserable.

The law of the land makes the consent of the parents necessary, under certain restrictions.

Duty of parents, C. 9.

Is of great importance in the class of duties from its general consequences.

Admits of definite rules, which may be explained under the heads of

1st. Maintenance,

Because somebody must maintain the children, and parents have no right to burthen others.

Nature indicates it in the person of the mother.

The Scriptures order it.

2d. Education;

Because necessary for the child's well-being in society.

3. A reasonable provision for the child's happiness in respect to outward condition, which requires three things.

1st. A situation suited to his reasonable expectations and habits.

2d. A provision for that situation.

(These articles must vary with the condition of the parent.)

Hence children should be preserved in that class in which they were born, or in which others of similar expectations are accustomed to be placed.

Hence a parent is justified in making a difference in his children according as they stand in greater or less need of his fortune from circumstances.

After their exigencies, the expectations of children may be satisfied according to primogeniture.

This point, together with general expediency, makes the difference of claim between legitimate children and bastards.

Still a parent is bound to provide for a bastard.

After a provision for exigencies, a parent may proportion his childrens' shares according to their behaviour.

Disinherison, nearly absolute, is justifiable only in case of utter incapability of managing an inheritance.

The third thing required in a provision for the child's happiness, is a probable security for his virtue.

This may be attained,

1st. By impressing on his mind the idea of accountableness.

2d. By shewing a good example.

3d By correcting his early inclinations, and disposing of him in a situation least dangerous to his particular character.

The rights of a parent, C. 10. *b.* 3. *p.* 3.

(That is, such as may be enforced by coercion) result from their duties.

A parent has a right to that authority, which is necessary in the exercise of his duties.

Hence a guardian has the same.

Parents have a right to choose professions for their children;

Because it is necessary to determine before they can judge for themselves.

In competition of commands the wife here also owes obedience to her husband.

Parents have no right over the lives of their children, or to sell them into slavery.

They exceed their authority when they consult their own interest at the expence of their children's happiness.

Duty of children. C. 11.

May be considered,

1st. During childhood.

Here the children's submission must be implicit.

2d. After they have attained to manhood, and continue in their parent's family.

Beside the general duty of gratitude to parents, they are bound to observe the regulations of the family.

3d. After they have attained to manhood, and have left their father's family.

In this state the duty to parents is simply the duty of filial gratitude, which just so much exceeds other obligations, by how much a parent has been a greater benefactor than any other friend.

It requires of children to endeavour by every means to promote their parents' comfort, and to contribute to their support, if they stand in need of it.

A parent has no right to destroy his children's happiness.

He has therefore no right to oppose his children's marriage where they have a real inclination, or to force them upon one which they dislike.

In this latter case the child must become guilty of prevarication; and parental, like all human authority, must cease, where obedience is criminal.

Nor has a parent a right to compel a child to choose a profession, to which he may be averse.

In every case the child is bound by gratitude to try earnestly, and with sincerity, to conquer his own inclinations, before he may act for himself.

A parent has no right to interfere, where a trust is reposed personally in the son. Vide B. 3. p. 2. c. 11.

The duty of children is commanded by God.

Duties to ourselves. B. 4.

This division is retained for the sake of method.

Whether in a state of nature we may defend the most insignificant perfect right by any extremity is very doubtful. B. 4. c. 1.

Because we cannot so easily balance between the general consequences of yielding, and the particular effect of resistance, which the person attacked is bound to do.

This right is suspended by the establishment of civil society.

Hence the individual injured is bound to submit to public arbitration.

Where it may be necessary for our preservation, all extremities are justifiable.

This is evident in a state of nature, nor is the case altered in civil society.

Because, by supposition, the laws cannot interpose to protect, nor can they compel restitution.

The defence of chastity seems to justify the same extremities.

In other cases the law of the land is our best guide.

Hence homicide, in England, is justifiable.

1st. In preventing the commission of a crime, which when committed would be punishable with death.

2d. In necessary endeavours to carry the law into execution.

N. B. The rights of war are not here taken into the account.

Drunkenness. C. 2.

Casual excesses incur all, in some degree, of the guilt and danger which attend habitual drunkenness;

We compute the guilt of it from its bad effects, which consist,

1st. In its betraying most constitutions into extravagances of anger or sins of lewdness.

2d. It disqualifies men for the duties of their station.

3d. It is attended with expences, which can seldom be spared.

4th. It creates uneasiness to the family of the drunkard.

5th. It shortens life.

These consequences may not all meet in the same subject; but the great mischief of example is sure always to ensue.

It is forbidden in the Scriptures.

The guilt of any action of a drunken man bears the same proportion to the guilt of the like in a sober man, that the probability of its being the consequence of drunkenness bears to certainty.

Suicide, B. 4. *c.* 3.

Rests on this question. "May every man who pleases to destroy his life, innocently do so?"

Whatever rule or limit for suicide is assigned, must lead to a toleration of it in all cases in which there is danger of its being committed.

The general consequences of such toleration would be,

1st. The loss to the community of many valuable lives.

2d. The affliction of many families, and consternation of all.

3d. The throwing off an opportunity of meliorating our condition in a future state.

Every case must also be aggravated by particular consequences.

Scripture implies the sin of suicide,

1st. By speaking of human life as a term prescribed to us.

2d. By inculcating patience as a great virtue.

3d. By the conduct of the apostles.

The above does not argue against the right of a state over the lives of its subjects.

Because the state receives this power not from the consent of collected individuals, but from the will of God. B. 4. c. 4.

Duties towards God, B. 5.

Signify duties, of which God is the object.

Silent piety, acceptable as it is to God, does not supersede the external duties; which may be divided into worship and reverence.

Worship is made up of adoration, thanksgiving, and prayer;

Prayer comprises them all.

Of the duty and efficacy of prayer, as it appears from the light of nature. C. 2.

It is probable God expects those intreaties from us, which we naturally use to every being on whom we depend.

The same may be said of thanksgiving.

Prayer is necessary to keep up a sense of God's agency.

The duty of prayer depends on its efficacy;

Which the perfect wisdom of the Deity does not argue against.

For he may withhold a favour unless requested by prayer;

1st. Because, on that very account, it may produce good effects on the person.

2d. Because it may encourage devotion.

3d. Because prayer has a tendency to amend the petitioner himself.

It is not necessary to devotion that the petitioner should know the circuit of causes by which his prayers may prevail.

We have no proof that inexorability is a part of that perfect wisdom which is explained to consist in bringing about the most beneficial ends by the most beneficial means.

To say God must act by one, or any rule, is to assert what is beyond our comprehension.

It is no objection to the efficacy of prayer that the effects of it are not always obvious,

Because it is beneficial that they should not be.

The custom of employing one person to intercede for many is justifiable,

For the happiness of many often depends on the good offices, and why may it not on the intercessions, of one individual.

Of the duty of prayer as represented in Scripture. C. 3.

The Scriptures not only affirm the propriety of prayer in general, but furnish precepts which justify particular topics and modes of prayer.

They teach the duty and efficacy of prayer in general.

Also of prayer for particular favours by name;

Of prayer for public national blessings;

Of intercession for others;

Of the repetition of unsuccessful intreaties.

Private prayer, family prayer, public worship. C. 4.

Each has its use, and therefore does not supersede the others.

Private prayer enables men to state wants, which cannot be the subject of public prayer. S. 1.

It is generally accompanied with more actual and solemn thoughts, which make a lasting impression.

It is particularly sanctioned by our Saviour.

Family prayer. S. 2.

Is particularly useful from its influence upon the members of a family.

Public worship. S. 3.

By this means a great part of mankind are instructed in religious knowledge, who would otherwise not be.

As the general consequences of the example are good, every individual is bound by the general rule to attend.

Public worship has also these advantages,

1st. It has a tendency to unite mankind together, and to enlarge the generous affections.

2d. It promotes humility in the higher, and proper dignity in the lower class of mankind, by placing them under the impression of considering their equal relation to the Deity.

Of form of prayer in public worship. C. 5.

Liturgies not being enjoined or forbidden in Scripture must be judged of by their expediency.

A liturgy,

1st. Prevents absurd or extravagant addresses to God.

2d It prevents the confusion of extempore prayer.

3d. It supplies, in some measure, the imperfections of the deliverer.

Joint prayer, which is the end of a congregation, without a liturgy, is impossible.

Our Saviour authorises a fixed form of prayer by appointing the Lord's prayer.

The properties required in a liturgy are,

1st. That it be compendious.

Brevity may be studied too much, for it is necessary that the attention, which slumbered in one part, may be recalled in another.

2d. That it express just conceptions of the divine attributes,

Because by it the popular notions of God are formed.

3d. That it recite such wants as the congregation are likely to feel, and no other.

Upon this principle our state prayers are too long.

4th. That it contain as few controverted propositions as possible.

The use of sabbatical institutions. C. 6.

That seasons should be set apart for religious worship is founded on the reasons that make worship a duty.

That they be at stated intervals, and be observed by all at the same time, is easiest and best for the community.

The day appointed may be Sunday, as well as any other day.

This reasoning refers only to the time occupied in divine service.

The manner of the christian sabbath is to be defended upon its general expediency.

1st. It contributes better to the happiness of the laborious part of mankind than any casual indulgencies of leisure.

(Nothing is lost by this interruption of public industry.)

2d. It leaves an opportunity for religious meditation.

3d. It gives happiness to the brute creation.

Of the Scripture account of sabbatical institutions. C. 7.

The Jewish sabbath was first instituted in the wilderness.

For it is never mentioned till then, and Ezekiel and Nehemiah speak of it as being so.

The historian in Gen. c. 2. writing after it was instituted, there gives the reason of its institution.

The Jews abstained from every kind of work, and permitted their slaves and cattle to rest; they sacrificed double sacrifice, and held holy convocations on this day.

Two questions concern the christian moralist,

1st. "Whether the command by which the Jewish sabbath was instituted extends to Christians?"

It appears not;

For it seems to have been part of the peculiar law of the Jewish policy;

Because it was first immediately directed to the Jewish people alone.

The sabbath is described as a sign between God and the people of Israel.

It is in its nature a ceremonial institution, like other seasons appointed by the Levitical law.

If it be binding on Christians, it must bind as to the day, &c. which are not regarded.

The observance of the sabbath is not one of the articles enjoined by the apostles in Acts, 15th chap. St. Paul mentions it as a Jewish ritual.

The two objections to the command's not being of universal obligation are,

1st. The reasons given for it in the fourth commandment.

2d. Its being one of the decalogue.

These are of no weight:

The first; because different reasons were given to account for different circumstances in the command;

The second; because in the Scriptures, positive duties, which are of partial, and natural, which are of universal obligation, are indiscriminately enumerated.

The second question is, "Whether Christ delivered any new command upon the subject, or whether any day was appropriated to the service of religion by the authority or example of the apostles?"

It appears that there was,

Because the holding of religious assemblies on the first day of the week was so early and universal a custom in the christian church.

The apostles seem to have practised it.

A cessation upon that day from labour was not ordered,

Because the Jews, to whom the gospel was first preached, had already a sabbath of rest.

It does not appear that Christ or his apostles meant the Jewish custom to be retained, the day only being changed.

From all above it appears,

That assembling upon the first day of the week for divine worship is a law of christianity;

That the resting on that day is a human institution;

Which is binding on individuals because of its beneficial general consequences,

And is recommended by its subserviency to many of the uses for which God appointed it to the Jews.

By what acts and omissions the duty of the christian sabbath is violated. C. 8.

The duty of the day is violated by whatever opposes the uses of its institution. Vide C. 6.

Wherefore it is violated,

1st. By any engagement, which hinders our attention on divine worship, or giving some time to religious meditations.

2d. By unnecessary encroachments on the rest and liberty of those, who may be under our authority.

3d. By such recreations as are usually forborne from respect to the day.

Any encroachment upon the line of distinctions in this latter instance is wrong, because pernicious in its general consequences.

Gaming upon this day cannot be harmless, on account of its effect upon the temper of the mind.

Of reverencing the Deity. C. 9.

A sense of awe whenever the idea of the Supreme Being is presented to the thoughts, is a considerable security against vice.

It is the effect of habit.

Levity in speaking of the Deity destroys this habit.

God, perhaps for this reason, forbade the vain mention of his name.

Our Saviour extends the prohibition to every thing associated with the idea of God.

The offence of profane swearing is aggravated by the slenderness of the temptation to it.

Ridicule upon the Scriptures falls within the mischief of the law, which forbids the profanation of God's name; especially as it is extended by Christ.

That man can have little regard for his own welfare in a future state, who respects not every, the most trivial attention to it in another person.

Such is the infidel, who mocks at the superstitions of the vulgar.

One unbeliever assumes the follies, which have adhered to the creed, as the doctrines of Christians, endeavouring thereby to subvert the whole system.

Another relates the vices of the sacerdotal order, endeavouring thereby to connect the character of the clergy, with the truth of christianity.

A third triumphs in collecting accounts of the wars and massacres occasioned by religious zeal, as if the vices of Christians were parts of christianity.

A fourth displays the succession and variety of popular religions, representing christianity as the superstition of the day.

These men aim at victory, not at truth,

Therefore can have no religious frame of mind.

They transgress the laws of reasoning and decency, and do not act honestly with mankind;

Because by matter calculated to produce effects beyond its real weight, they try to cheat men of a belief in a religion, which holds forth assurances of immortality.

The dishonesty is greater where the matter comes in the dress of insinuation, a sneer, or, as has been the case, of obscenity.

The latter works its effect independent of reason.

A sneer, who can refute?

They are both as formidable to a true religion, as a false one.

This licentiousness can scarcely be tolerable even to those men, who see little in christianity, supposing it to be true.

Let this class of reasoners reflect,

That if Christ had delivered no other declaration than, "The hour is coming, in the which all that are in the graves shall hear his voice, and shall come forth; they that have done good, unto the resurrection of life, and they that have done evil, unto the resurrection of damnation;" he had pronounced a message of inestimable importance.

A future state had never before been discovered, because it had never been proved; and no man can prove this point, but the teacher who testifies by miracles that his doctrine comes from God.

Moral sense, the faculty whereby we discern or perceive what is good, virtuous, beautiful, &c. in actions, manners, characters, &c.

A late author has endeavoured to prove, that it is a peculiar sense whereby we get the ideas of these things; and denominates it a moral sense. See Sense.

MO'RALIST. *s.* (*moraliste*, French.) One who teaches the duties of life (*Addison*).

MORA'LITY. *s.* (*moralité*, Fr. from *moral.*) 1. The doctrine of the duties of life; ethics (*Baker*). See Moral philosophy. 2. The form of an action which makes it the subject of reward, or punishment (*South*).

To **MO'RALIZE.** *v. a.* (*moraliser*, Fr.) To apply to moral purposes; to explain in a moral sense (*L'Estrange*).

To **Mo'ralize.** *v. n.* To speak or write on moral subjects.

MO'RALIZER. *s.* (from *moralize.*) He who moralizes.

MO'RALLY. *ad.* (from *moral.*) 1. In the ethical sense (*Rymer*). 2. According to the rules of virtue (*Dryden*). 3. Popularly (*L'Estrange*).

MO'RALS. *s.* (without a singular.) The practice of the duties of life; behaviour with respect to others (*South*).

MORASS, a marsh, fen, or low moist ground, which receives the waters from above without having any descent to carry them off again. Somner derives the word from the Saxon *merse*, lake; Salmasius from *mare*, a collection of waters; others from the German *marast*, a muddy place; and others from *maresc* of *maricitum*, *a mariscis*, i. e. rushes. (See Bog, Fen, and Draining.) In Scotland, Ireland, and the north of England, they have a peculiar kind of morasses called mosses or peat-mosses, whence the country people dig their peat or turf for firing. See Moss.

MORAT, a town of Swisserland, in the Vaudois, situated on the south-east side of a lake, to which it gives name. Near it is a chapel, filled with the bones of the Burgundians who perished in the siege of this town, in a battle with the Swiss, in the year 1476. It is the capital of a district: twelve miles W. Berne, and twenty-two S.S.W. Soleure.

MORAVA, or Moraw, a river of Germany, which has its source on the confines of Bohemia and Silesia. It crosses Moravia, where it waters Olmutz and Hradisch, and receiving the Toya, from the confines of

Lower Hungary and Upper Austria, separates these two countries as far as the Danube, into which it falls.

MORAVIA (Marquisate of), a country of Germany, bounded on the north by Bohemia and Silesia, on the east by Silesia and Hungary, on the south by Austria, and on the west by Bohemia; containing about 1400 square miles. Towards Hungary, Bohemia, and Silesia, it is partly environed by mountains, and partly by woods. Above one half of it is mountainous and woody, and many of the former are so rough, as to be almost desolate. In the more champaign circles, tracts, and parts, are many morasses, bogs, and lakes. In the mountainous regions, the air, indeed, is rough and cold, so that in many places, for near the whole summer, the inhabitants must use a stove; but these parts, notwithstanding, are wholesomer than the abovementioned champaign territories. More corn grows here than the inhabitants consume. In it is also plenty of hemp and flax; nor are table fruit-trees or vegetables wanting. It produces, likewise, good saffron. Some white and red wine is made in those tracts lying towards Hungary and Austria, which are in no respect inferior to the Austrian territories. The pasturage is good, and maintains all sorts of cattle. It is remarkable, that in some places they also dig frankincense and myrrh out of the earth. Game is plentiful. There is no want of venison here; there are likewise wolves, bears, and a species of leopards, of the size of dogs, but thicker, which are called Rysowe, with some beavers. In the circle of Brunn, are quarries of marble, bastard diamonds, amethysts, and other minerals, alum, iron mines and works. In the circle of Znaym, were formerly mines of gold; and, at this day, are some of iron, sulphur, salt-petre, and vitriol. Here and there are some mineral springs, which are impregnated with sulphur, alum, vitriol, and salt-petre; and there are likewise acid springs, but salt they want. The number of towns, villages, and market-towns in Moravia, has been estimated at 2550. The language of the inhabitants is a dialect of the Sclavonic, and little differing from the Bohemian. The German language, too, is very common in Moravia. The states of the country consist of the clergy, lords, knights, and burgesses. Christianity was introduced so early as the eighth century. The whole country is of the Roman Catholic church, and subject to the ecclesiastical jurisdiction of the bishop of Olmutz. The principal articles of commerce consist in their manufactures of cloth, iron, glass, paper, gunpowder, &c. which, on the whole, are considerable. Moravia was anciently inhabited by the Quadi, who were driven out by the Sclavi. While belonging to the latter, it was of greater extent than at present. The kings of this country were, till the ninth century, powerful and independent; but afterwards, the emperor Charlemagne not only vanquished king Lech, but his son and successor Louis made king Mogemir also his vassal. A part of it, which, to this day, alone bears the name of Moravia, the Bohemian dukes Brzetislaw and Ulrich, in 1026, reduced by force of arms; and the former, on his death, was reckoned among the princes thereof. From that time, this country having, in the year 1086, been declared a marquisate by the German king, Henry IV, and united with Bohemia, has been frequently resigned as a fief, by the dukes and kings of Bohemia to their sons, brothers, or relations, and sometimes even divided. Since the time of king Matthias, Moravia has enjoyed no peculiar margrave of its own, but has constantly remained annexed to the crown of Bohemia. Moravia contributes about one-third part to the exactions which Bohemia pays. Towards the maintenance of the military state of the whole Austrian heriditary countries, it contributes yearly 1,856,490 florins. Seven regiments of foot, one of cuirassiers, and one of dragoons, are at present quartered in Moravia. The whole marquisate is divided into six circles, each of which has its circle-captain, whose authority extends to the quartering, marching, and maintenance of the soldiers. Olmutz is the capital.

MORAVIANS, HERRNHUTTERS, or UNITAS FRATRUM, in church history, a denomination of Christians, concerning whose origin, history, and character, various contradictory reports have been published. Crantz divides their history into what he calls ancient and modern. The former refers to them before the time of their settlement in Upper Lusatia, in 1722; the latter after that period. The United Brethren claim the famous Huss, and Jerome of Prague, as their martyrs. M. Crantz, however, places the beginning of the church of the United Brethren in the year 1457, and says, that it arose out of the scattered remains of the followers of Huss. In the year 1450 this people became re-united to the Greek church; but on the taking of Constantinople by the Turks about two years afterwards, that union was again dissolved. After this, various attempts were made to form them into a regularly constituted church, but without success. At length, after many vexations and commotions among themselves, and sundry persecutions from others, they obtained permission to withdraw to a part of the king's domain, on the boundary between Silesia and Moravia. In the same year, 1457, they formed their church fellowship, calling themselves Unitas Fratrum, or Fratres Unitatis, the United Brethren. From this period to the Reformation they suffered many cruel and vexatious persecutions; yet they preserved their unity, and formed a kind of alliance with the Waldenses, who had for many centuries opposed many of the corrupt practices and doctrines of the Romish church. After the Reformation, they professed to adhere to the Augsburgh Confession, yet they continued a distinct body. After various persecutions and discouragements, during the seventeenth century, they became in a manner extinct; until about the year 1720, when they began to revive in Bohemia; but as no free toleration could be obtained for them in that country, they agreed to emigrate. Applications were accordingly made to Nicholas Lewis, count of Zinzendorf, who readily granted them permission to settle on his estates in Upper Lusatia. Thither, in 1722, a company of them repaired, and formed the settlement of Herrnhut, from whence they are sometimes called Herrnhutters. Their friend and protector, count Zinzendorf, at length became a convert to the faith and practices of the Moravian Brethren, and commencing preacher, was, in the year 1735, chosen to be their bishop. From this period the sect of the Moravians began to flourish rapidly. Count Zinzendorf was a zealous and enterprising man, though in some respects enthusiastical and mystical. His exertions were of singular service to the cause of the brethren, though his extravagancies sometimes brought them into contempt with the sober and reflecting part of mankind. It is even acknowledged, on the part of the count's friends, that much of the extravagance and absurdity that has been attributed to him owes its origin, or at least its publication, to those persons who wrote his extempore sermons in short-hand, and afterwards published them with all their imperfections about them.

The church of the United Brethren is episcopal, and their church government is conducted with great form and regularity. Questions of dispute are settled by ballot, and in cases of real or supposed importance are often decided by lot. The lot is deemed a solemn appeal to heaven, and is made use of with great seriousness. They have œconomies, or choir-houses, where they live together in community; the single men and single women apart, widows and widowers apart, each under the superintendance of elderly persons of their own class. At Fairfield, near Manchester, there is a Moravian settlement; it is a small village, uncommonly neat and clean, consisting of one large open street, having a handsome chapel, and a small public-house for the reception of strangers who visit the settlement from Manchester and the neighbourhood, particularly on Sundays and other holidays.

The Moravians have also another settlement and school in a very secluded and in some respects romantic situation, at Fulneck, near Leeds; where some men of learning and taste as well as piety have been educated; especially that tender and mournfully exquisite poet James Montgomery.

Christians of this class are very strict in their attention to the youth of both sexes, and never suffer them to come together or to marry without the previous consent of the church; and as the lot must be cast to sanction their union, each receives his partner as a divine appointment. Though the Moravians are united in one body, they are by no means illiberal in their views towards other Christians, who hold what they conceive to be the essentials of religion, and pay divine adoration to Jesus Christ. In doctrine they appear to be inclined to Sabellianism. They address many of their prayers to Jesus as the lamb; and their hymns, being an uncouth translation from the German, often offend the ears of critical persons; especially if their criticism is not softened by the candour of genuine piety. Let their taste and learning, however, be much or little, the Moravians are a very harmless and unoffending people. They appear to be Arminians in opposition to Calvinism, and they reject the use of the term Trinity, and some other popular and unscriptural terms and phrases. In zeal, tempered with modesty, and in silent perseverance in attempting to convert the heathen world to Christianity, the Moravians are unequalled. The Moravian missionaries are quietly and successfully pursuing their labour of love in almost every part of the known world. They have settlements in various parts, particularly in the following places: begun 1732, in the Danish West India Islands; in St. Thomas, New Herrnhut, Nisky; in St. Croix, Friedensburg, Friedenstal; in St. Jan, Bethany, and Emmaus. In 1733, in Greenland, New Herrnhut, Lichtensels, and Lichtenau. In 1734, North America, Fairfield in Upper Canada, and Goshen on the river Muskingum. In 1736, at the Cape of Good Hope, Bavians Kloof. In 1738, in South America, among the negro slaves at Paramaribo and Sommelsdyk; among the free negroes at Bambey, on the Sarameca, and among the native Indians at Hope on the river Corentyn. In 1754, in Jamaica, two settlements in Elizabeth parish. In 1756, in Antigua, at St. John's, Grace hill, and Grace bay. In 1760, near Tranquebar in the East Indies, Brethren's Garden. In 1764, on the coast of Labrador, Nain, Okkak, and Hopedale. In 1765, in Barbadoes, Sharron near Bridgetown. In the same year, in the Russian part of Asia, Sarepta. In 1775, in St. Kitt's, at Basseterre. In 1789, in Tobago, Signal Hill. By the latest accounts published, most of these settlements appear to be in a flourishing state.

Whoever wishes to see a more detailed account of the Moravians will do well to consult Crantz's Ancient and Modern History of the United Brethren, the same author's History of the Mission in Greenland, La Trobe's edition of Spangenburgh's Exposition of Christian Doctrine, also Rimius's Narrative of the Moravians, Bishop Lavington's Moravians compared and detected, and the Periodical Accounts of the Missions of the United Brethren; the latter of which are very interesting not only in a religious, but in a geographical point in view, as they contain the best accounts of the interior of America which have yet been published.

MORAW. See Morava.

MORBACH, or Murbach, a town of France, in the department of Lower Rhine, 42 miles south-east of Strasburg. Lon. 8. 25 E. Lat. 48. 0 N.

MORBEGNO, a town of the country of the Grisons, in the Valteline, where the governor and the regency reside. It is the handsomest and most commercial town in the Valteline, and seated on the Adda, 12 miles S.E. of Chiavenna, and 20 N.E. of Lecco. Lon. 9. 31 E. Lat. 46. 10 N.

MO'RBID. *a.* (*morbidus*, Lat.) Diseased; in a state contrary to health (*Arbuthnot*).

MO'RBIDNESS. *s.* (from *morbid.*) State of being diseased.

MORBI'FICAL. MORBI'FIC. *a.* (*morbus* and *facio*, Lat.) Causing diseases (*Harvey*).

MORBILLI. (*morbillus*, of *morbus*, a disease.) See RUBEOLA.

MORBO'SE. *a.* (*morbosus*, Lat.) Proceeding from disease; not healthy (*Ray*).

MORBO'SITY. *s.* (from *morbosus*, Lat.) Diseased state: not in use (*Brown*).

MORBUS COMITIALIS, a name given to the epilepsy; because if on any day when the people were assembled in *comitia* upon public business, any person suddenly seized with this disorder should fall down, the assembly was dissolved, and the business of the *comitia*, however important, was suspended. See COMITIA.

MORBUS REGIUS, the same with the jaundice. See MEDICINE.

MORBUS, or DISEASE, in botany. See VARIETAS.

MORDA'CIOUS. *a.* (*mordax*, Lat.) Biting; apt to bite.

MORDA'CITY. *s.* (*mordacitas*, Latin.) Biting quality (*Bacon*).

MORDANT. (*mordant*, from *mordre*, to bite, Fr.) An intermede, or substance used in dyeing, to enable the dye or colouring matter to adhere to the material to be coloured, and which it was formerly supposed to do, by biting or eating its way into the texture of such material, whence its name. A better knowledge, however, of the chemical properties of bodies has now taught us that this effect is produced not by any corrosive property in the substance denominated a mordant, but in consequence of its equal attraction or affinity for the colouring material and the material to be coloured, by which they are kept in a state of union. The colours thus requiring to be united by a third substance are denominated adjective; those which possess a natural affinity for the material to be coloured, and of course are capable of adhering to it without any such assistance, are called substantive colours. See for the different kinds of mordants and their mode of action the article DYEING.

MORDELLA. Nibbler. In zoology, a genus of the class insecta, order coleoptera. Antennas moniliform or pectinate; head deflected and bent under the neck; shells curved downwards towards the tip; at the base of the abdomen and towards the thighs is a broad lamina. Thirty-four species, chiefly inhabitants of Europe; a few of Asia, Africa, and America; nine indigenous to our own country, and found on garden-flowers. They may be thus subdivided:

A. Antennas moniliform; fore-feelers clavate, hind-feelers filiform.

B. Antennas pectinate; feelers filiform. The tribe denominated kipiphorus by Fabricius, embracing twelve species.

MO'RDICANT. *a.* (*mordeo*, Lat. *mordicant*, Fr.) Biting; acrid (*Boyle*).

MORDICA'TION. *s.* (from *mordicant.*) The act of corroding or biting (*Bacon*).

MORE. *a.* (maꞃe, Saxon.) 1. In greater quantity; in greater degree (*Shak.*). 2. In greater number (*Cowley*). 3. Greater: not in use (*Acts*). 4. Added to some former number (*Pope*).

MORE. *ad.* 1. To a greater degree (*Bacon*). 2. The particle that forms the comparative degree; as, *more* happy (*Bacon*). 3. Again; a second time (*Tatler*). 4. Longer; yet continuing: with the negative particle; *he lives no* more (*Shakspeare*).

MORE. *s.* 1. A greater quantity; a greater degree (*Shakspeare*). 2. Greater thing; other thing: *he did* more *than his fellows* (*Locke*). 3. Second time; longer time: *he will come no* more (*Pope.*)

MORE (Sir Thomas), lord high chancellor of England, the son of sir John More, knight, one of the judges of the King's-bench, was born in the year 1480, in Milk-street, London. He was first sent to a school at St. Anthony's in Threadneedle-street; and afterwards introduced into the family of cardinal Moreton, who in 1497 sent him to Canterbury college in Oxford. During his residence at the university he constantly attended the lectures of Linacre and Grocinus, on the Greek and Latin languages. Having in the space of about two years made considerable proficiency in academical learning, he came to New-inn in London, in order to study the law; whence, after some time, he removed to Lincoln's-inn, of which his father was a member. Notwithstanding his application to the law, however, being now about twenty years old, he was so bigotted to monkish discipline, that he wore a hair-shirt next his skin, frequently fasted, and often slept on a bare plank. In the year 1503, being then a burgess in parliament, he distinguished himself in the house, in opposition to the motion for granting a subsidy and three fifteenths for the marriage of Henry VII.'s eldest daughter, Margaret, to the king of Scotland. The motion was rejected; and the king was so highly offended at this opposition from a beardless boy, that he revenged himself on Mr. More's father, by sending him on a frivolous pretence to the Tower, and obliging him to pay 111*l.* for his liberty. Being now called to the bar, he was appointed law-reader at Furnival's-inn, which place he held about three years; but about this time he also read a public lecture in the church of St. Lawrence, Old Jewry, upon St. Austin's treatise *De civitate Dei*, with great applause. He had indeed formed a design of becoming a Franciscan friar, but was dissuaded from it; and, by the advice of Dr. Colet, married Jane, the eldest daughter of John Colt, Esq. of Newhall in Essex. In 1508 he was appointed judge of the sheriff's court in the city of London, was made a justice of the peace, and became very eminent at the bar. In 1516 he went to Flanders in the retinue of Bishop Tonstal and Dr. Knight, who was sent by king Henry VIII. to renew the alliance with the archduke of Austria, afterwards Charles V. On his return, cardinal Wolsey would have engaged Mr. More in the service of the crown, and offered him a pension, which he refused. Nevertheless, it was not long before he accepted the place of master of the requests, was created a knight, admitted of the privy-council, and in 1520 made treasurer of the exchequer. About this time he built a house on the bank of the Thames, at Chelsea, and married a second wife. This wife, whose name was Middleton, and a widow, was old, ill-tempered, and covetous; nevertheless Erasmus says he was as fond of her as if she were a young maid.

In the 14th year of Henry VIII. sir Thomas More was made speaker of the house of commons: in which capacity he had the resolution to oppose the then powerful minister, Wolsey, in his demand of an oppressive subsidy; notwithstanding which, it was not long before he was made chancellor of the duchy of Lancaster, and was treated by the king with singular familiarity. The king having once dined with sir Thomas at Chelsea, walked with him near an hour in the garden, with his arm round his neck. After he was gone, Mr. Roper, sir Thomas's son-in-law, observed how happy he was to be so familiarly treated by the king: to which sir Thomas replied, "I thank our lord, son Roper, I find his grace my very good lord indeed, and believe he doth as singularly favour me as any subject within this realm: howbeit, I must tell thee, I have no cause to be proud thereof; for if my head would win him a castle in France, it would not fail to go off." From this anecdote it appears, that sir Thomas knew his grace to be a villain.

In 1526 he was sent, with cardinal Wolsey and others, on a joint embassy to France, and in 1529 with bishop Tonstal to Cambray. The king, it seems, was so well satisfied with his services on these occasions, that in the following year, Wolsey being disgraced, he made him chancellor; which seems the more extraordinary, when we are told that sir Thomas had repeatedly declared his disapprobation of the king's divorce, on which the great *defensor fidei* was so positively bent. Having executed the office of chancellor about three years, with equal wisdom and integrity, he resigned the seals in 1533, probably to avoid the danger of his refusing to confirm the king's divorce. He now retired to his house at Chelsea; dismissed many of his servants; sent his children with their respective families to their own houses (for hitherto he had, it seems, maintained all his children, with their families, in his own house, in the true style of an ancient patriarch); and spent his time in study and devotion: but the capricious tyrant would not suffer him to enjoy his tranquillity. Though now reduced to a private station, and even to indigence, his opinion of the legality of the king's marriage with Anne Boleyn was deemed of so much importance, that various means were tried to procure his approbation; but all persuasion proving ineffectual, he was, with some others, attainted in the house of lords of misprision of treason, for encouraging Elizabeth Barton, the nun of Kent, in her treasonable practices. His innocence in this affair appeared so clearly, that they were obliged to strike his name out of the bill. He was then accused of other crimes, but with the same effect; till, refusing to take the oath enjoined by the act of supremacy, he was committed to the Tower, and, after fifteen months imprisonment, was tried at the bar of the King's-bench for high treason, in denying the king's supremacy. The proof rested on the sole evidence of Rich the solicitor-general, whom sir Thomas, in his defence, sufficiently discredited; nevertheless the jury brought him in guilty, and he was condemned to suffer as a traitor. The merciful Harry, however, indulged him with simple decollation: and he was accordingly beheaded on Tower-hill, on the 5th of July 1535. His body, which was first interred in the Tower, was begged by his daughter Margaret, and deposited in the chancel of the church at Chelsea, where a monument, with an inscription written by himself, had been some time before erected. This monument with the inscription is still to be seen in that church. The same daughter, Margaret, also procured his head after it had remained fourteen days upon London-bridge, and placed it in a vault belonging to the Roper's family, under a chapel adjoining to St. Dunstan's church in Canterbury. Sir Thomas More was a man of learning, and an upright judge; a very priest in religion, yet cheerful, and even affectedly witty. He wanted not sagacity, where religion was out of the question; but in that his faculties were so enveloped, as to render him a weak and credulous enthusiast. He left one son and three daughters; of whom Margaret, the eldest, was very remarkable for her knowledge of the Greek and Latin languages. She married a Mr. Roper of Wellhall in Kent, whose life of sir Thomas More was published by Mr. Hearne at Oxford in 1716. Mrs. Roper died in 1544; and was buried in the vault of St. Dunstan's in Canterbury, with her father's head in her arms.

Sir Thomas was the author of various works, though his Utopia is the only performance that has survived in the esteem of the world; owing to the rest being chiefly of a polemic nature: his answer to Luther has only gained him the credit of having the best knack of any man in Europe at calling bad names in good Latin. His English works were collected and published by order of queen Mary, in 1557; his Latin, at Basil, in

1563; and at Louvain, in 1566. The life of this great man has been written by several persons in the course of the last and present century: very interesting memoirs are given in Dr. Wordsworth's Ecclesiastical Biography.

More (Henry), an ingenious English divine, was born at Grantham in Lincolnshire in 1614, and educated first at Eton school, and next at Christ college, Cambridge; where he applied himself to the study of the platonic writers, whose sentiments he strongly imbibed. In 1675, being then D.D. he accepted a prebend in the cathedral of Gloucester, but would never take any higher perferment, though a bishopric was offered him of considerable value. He died in 1687, and was buried in the chapel of Christ college. His philosophical works have been published in one volume folio; and his theological works in another volume folio.

More (Alexander), a French protestant divine, was the son of a Scotchman, who was principal of the college at Castres in Languedoc, where this son was born in 1616. He studied at Geneva, and became professor of divinity, and minister at Middleburg, in 1649. He afterwards removed to Amsterdam, where he was chosen professor of history. From Holland he went to France, and was ordained pastor of the reformed church at Paris, where he died in 1670. He published some works, as a Treatise De Gratia et Literis Arbitira; a Reply to Milton's second Defence of the People of England, &c.

More (Sir Francis), a learned English lawyer, was a member of the Middle Temple, and died in 1621. His works are, 1. Cases collected and reported, London, 1693, folio. 2. Readings upon 4 Jac. I. in the Middle Temple, folio, 1676.

More (John), an English prelate, was born in Leicestershire, and educated at Clare-hall, Cambridge, where he took his degree of D.D. in 1681. After different church preferments, he was consecrated bishop of Norwich in 1691; and translated to Ely in 1707. He died in 1714. His sermons were published by Dr. Samuel Clarke, who was his chaplain. His magnificent library was purchased by George II. for 6000 guineas, and given to the university of Cambridge.

More (St. Anthonio), a celebrated painter, was a native of Utrecht, and a disciple of John Schorel. He drew the portraits of several crowned heads, particularly Mary queen of England, wife of Philip II. of Spain. He died at Antwerp in 1575, aged 56.

MOREA, a country of European Turkey, forming a peninsula united to the rest of Greece, by a narrow neck of land, called the Isthmus of Corinth, so famed for the Isthmian games, celebrated there, in honour of Neptune. It was anciently called Peloponnesus, and, in more remote times, Ægialea and Apia. It once consisted of the following small kingdoms: Sicyon, Argos, and Mycene, Corinth, Achaia Proper, Arcadia, and Laconia. Its present name of the Morea is said to be derived from Morus, a mulberry-tree, either from its resembling the leaf of that tree in shape, or from the great number of mulberry-trees it produces. It has not only several rivers, lakes, and mountains, but also many fertile and delightful plains. At the treaty of Carlowitz, the Turks ceded all the Morea to the Venetians, but, in the year 1715, again dispossessed them of it. It is divided into four districts.

MOREL. Phallus esculentus of Linnéus. It grows on moist banks and wet pastures, and springs up in May. It is used in the same manner as the truffle, for gravies and stewed dishes, but gives an inferior flavour. See **Phallus.**

Morel, or **Morella cherry.** See **Prunus.**

Morel, the name of several learned printers in France. William Morel died at Paris in 1564. Frederic, who was interpreter of the Greek and Latin tongues, and also printer to the king, died in 1583. His son, Frederic Morel, was also a very learned man, and died in 1630, after having printed a great number of valuable authors.

Morel (Andreas), a famous antiquary, was a native of Bern in Switzerland. He studied medals with intense application, and in 1683 published at Paris a work, entituled Specimen universæ rei nummariæ antiquæ, a second edition of which came out in 1695; but he never completed the work itself. Louis XIV. appointed him to a place in his cabinet; but for some offence or other he was sent to the Bastile, where he remained three years. On his release, he returned to Switzerland, and died there in 1703. In 1734 was published in 2 vols. folio, Thesaurus Morellianus, sive Familiarum Romanarum Numismata omnia, &c. This was part of his grand design above mentioned.

MORELL (Thomas), a learned English divine and lexicographer, was born in 1701, and died in 1784. He edited Ainsworth's Latin Dictionary, Hedericus's Greek Lexicon, and published a useful abridgement of the former work. After his death appeared, Annotations on Locke's Essay, by Dr. Morell, who also selected the scriptures for Handel's Oratorios. (*Watkins*).

MORELY (Lord), an ingenious nobleman, was the son of sir Thomas Parker, in the county of Essex, and a great favourite with Henry VIII. who raised him to the peerage. He contrived to secure that monarch's favour by concurring heartily in his divorce from Catherine, and marriage with Anne Boleyn. He died in 1747. This nobleman wrote several Latin poems.

MOREO'VER. *ad.* (*more* and *over.*) Beyond what has been mentioned; besides (*Shaks.*).

MORES (Edward Rowe), an English antiquary, was born in 1730 at Tunstall in Kent, and educated at Merchant Taylors' school, from whence he removed to Queen's college, Oxford, where he published a curious remain of antiquity, entituled, Nomina et Insignia Gentilitia Nobilium Equitumque sub Edwardo primo Rege Militantium, 4to. 1748. In 1752 he was chosen a fellow of the society of antiquaries; and he projected the equitable society for insurance on lives and survivorship by annuities. He was the author of several pieces, particularly the History and Antiquities of Tunstall in Kent, and a Dissertation on Founders and Founderies. He died in 1778.

MORINDA, in botany, a genus of the class pentandria, order monogynia. Flowers aggregate, one-petalled; stigma bifid; drupes aggregate. Three species: two of them East Indian, one a South American tree.

MORINGEN, a town of Suabia, in the principality of Furstenburg, 14 miles N.N.E. of Schaffhausen, and 26 N.W. of Constance. Lon. 3. 46 E. Lat. 47. 48 N.

Moringen, a town of Lower Saxony, in the principality of Calenberg, situate on the Mohr, 12 miles N.N.W. of Gottingen. Lon. 9. 49 E. Lat. 51. 40 N.

MORINI, a people of Belgic Gaul, on the shores of the British ocean. The shortest passage into Britain was from their territories. They were called *extremi hominum* by the Romans, because situate on the extremities of Gaul.

MORISON (Robert), physician and professor of botany at Oxford, was born at Aberdeen in 1620, bred at the university there, and taught philosophy for some time in it; but having a strong inclination to botany, made great progress in it. The civil wars obliged him to leave his country; which, however, he did not do till he had first signalized his zeal for the interest of the king, and his courage, in a battle fought between the inhabitants of Aberdeen and the presbyterian troops on the bridge of Aberdeen, in which he received a dangerous wound on the head. As soon as he was cured of it, he went into France; and fixing at Paris, he applied assiduously to botany and anatomy. He was introduced to the duke of Orleans, who gave him the direction of the royal gardens at Blois. He exercised the office till the death of that prince, and afterwards went over to England in 1660. Charles II. to whom the duke of Orleans had presented him at Blois, sent for him to London, and gave him the title of his physician, and that of professor royal of botany, with a pension of 200l. per annum. The Præludium Botanicum, which he published in 1669, procured him so much reputation, that the university of Oxford invited him to the professorship of botany, in 1669; which he accepted, and acquitted himself in it with great ability. He died at London, in 1683, aged 63. He published a second and third part of his History of Plants, in 2 vols. folio; with this title, Plantarum Historia Oxoniensis Universalis. The first part of this excellent work has not been printed; and it is not known what has become of it.

MORISONIA, in botany, a genus of the class monadelphia, order polyandria. Calyx single, bifid; petals four; pistil one; berry pedicelled, one-celled, many-seeded, with a hard bark. One species only; an American tree with oblong, entire, shining coriaceous leaves.

MORLACHIA, a mountainous country in Hungarian Dalmatia, the inhabitants of which are called Morlacks, or Morlacchi. They inhabit the pleasant vallies of Koter, along the rivers Kerha, Cettina, Narenta, and among the inland mountains of Dalmatia. They are said by some to be of Wallachian extraction; but others think their origin involved in the darkness of the barbarous ages. The inhabitants of the seacoast of Dalmatia tell many frightful stories of their avarice and cruelty; but these, abbe Fortis thinks, are all of an ancient date; or, if any such events have happened in later times, they ought rather to be ascribed to the corruption of a few individuals than to the bad disposition of the nation in general. For the most pleasing trait of character among the Morlacchi is friendship. They have even made it a kind of religious article, and tie the sacred bond at the foot of the altar. The Sclavonian ritual contains a particular benediction, for the solemn union of two male or two female friends, in the presence of the congregation. The male friends thus united are called probratimi, and the females posestreme, which mean half-brothers and half-sisters. Friendships between those of different sexes are not bound with so much solemnity, though perhaps in more ancient and innocent ages that was also the custom. From these consecrated friendships among the Morlacchi, and other nations of the same origin, it should seem that the sworn brothers arose, a denomination frequent among the common people in many parts of Europe. If discord happens to arise between two friends among the Morlacchi, it is talked of over all the country as a scandalous novelty; and there have been some examples of it of late years to the great affliction of the old Morlacchi, who attribute the depravity of their countrymen to their intercourse with the Italians.

MORLAIX, a seaport of France, in the department of Finistere, with a castle and a tide harbour. The church of Notre-Dame is a singular structure, and the hospital very handsome. The inhabitants carry on a considerable trade in linen, hemp, and tobacco. It is seated on a river of the same name, 30 miles N.E. of Brest, and 45 W. of St. Brieux. Lon. 3. 46 W. Lat. 48. 33 N.

MO'RLAND. *s.* (moꞃlanꝺ, Saxon.) A mountainous or hilly country.

MO'RLING. Mo'rtling. *s.* Wool plucked from a dead sheep (*Ainsworth*).

MORLUNDA, a town of Sweden, in the province of Smoland, 41 miles N. of Calmar. Lon. 16. 24 E. Lat. 57. 20 N.

MORMO. *s.* (μορμω.) Bugbear; false terrour.

MORMYRUS, in zoology, a genus of the class pisces, order branchiostega. Head smooth; teeth numerous, notched: aperture of the gills linear, without a cover; gill-membrane with one ray; body scaly. Three species:

1. M. cyprinoides. Tail bifid, appendaged. Inhabits the Nile.

2. M. anguilloides. Tail bifid, obtuse; dorsal fin with twenty-six rays. Inhabits the Nile.

3. M. kannume. Tail bifid, obtuse; dorsal fin with sixty-three rays: body whitish, much compressed. Like the two former, inhabits the Nile.

MORN. *s.* (maꞃne, Saxon.) The first part of the day; the morning (*Lee*).

MORNAC (Anthony), a French advocate, who was the author of four folio volumes on the subject of law; and also of an octavo volume of poems. He died in 1619.

MORNAY (Philip de), lord of Plessis Marlay, a celebrated French nobleman, was born in 1549, of a noble family. He was bred up by his mother in the protestant persuasion, and studied in several universities, both in France and other countries. In 1576 he went to the court of the king of Navarre, afterwards Henry IV. who received him very courteously, and made him minister of his council. In 1578 he published a treatise on the church; and in the year following began his famous work on the Truth of the Christian Religion. In 1598 he published his book on the Eucharist, which occasioned a conference between him and Du Perron; the result of which was so much in his favour that he was called by many the protestant pope. In 1607 he printed a famous book against popery, entitled, The Mystery of Iniquity, or the History of the Papacy. This great man died at his seat in Poictou, in 1623. He wrote many pieces besides those here mentioned.

MORNE-GAROU, a remarkable volcanic mountain on the island of St. Vincent's in the West Indies. It was visited by Mr. James Anderson, surgeon, in the year 1784, who is the only person that ever ascended to the top of it, and whose account of it is published in the Philosophical Transactions, vol. 75, or New Abridgment, vol. 60. p. 634.

MO′RNING. *s.* The first part of the day, from the first appearance of light to the end of the first fourth part of the sun's daily course.

MO′RNING. *a.* Being in the early part of the day (*Pope*).

MORNING-GOWN. *s.* A loose gown worn before one is formally dressed (*Addison*).

MORNING-STAR. *s.* The planet Venus when she shines in the morning (*Spenser*). Astronomers reckon morning, *mane*, from the time of midnight to that of mid-day or noon.

MOROC, in ornithology. See CUCULUS INDICATOR.

MOROCCO, an empire of Africa, comprehending a considerable part of the ancient Mauritania, lying between 28 and 36° N. lat. It is bounded on the W. by the Atlantic, on the E. by the river Muliva, which separates it from Algiers, on the N. by the Mediterranean, and on the S. by mount Atlas. Its greatest length, from N.E. to S.W. is above 590 miles, and, where widest, not more than 260 broad. The south part of the empire contains the kingdoms of Sus, Tarudan, Morocco Proper, Tasilet, and Sugelmessa; and the north part those of Fez and Mequinez. The air of this country is pretty temperate, especially near mount Atlas. The soil, though sandy and dry in some places, is fertile in others; and the fruits, as well as the pastures, are excellent, but the country is not properly cultivated. The inhabitants are Mahometans, of a tawny complexion, robust, and very skilful in managing a horse, and wielding a lance: they are jealous, deceitful, superstitious, and cruel. There are two sorts of inhabitants; the Arabs, who dwell in moveable villages, composed of about 100 tents, and the Bereberies, who are the ancient inhabitants, and live in cities and towns. There are a great number of christian slaves, and some merchants, upon the coast, beside a multitude of Jews, who carry on almost all the trade; especially by land with the negroes, to whom they send large caravans, which travel over vast deserts, almost destitute of water. They carry with them woollen goods, silk, salt, &c. and in return have slaves, gold, and elephants teeth. They also send large caravans to Mecca every year, partly out of devotion, and partly for trade, consisting of several thousand camels, horses, and mules. Besides woollen goods, their commodities are Morocco leather, indigo, cochineal, and ostrich feathers; in return for which they have silks, muslins, calicoes, coffee, and drugs. In the deserts are lions, tigers, leopards, and serpents of several kinds. The fruits are dates, figs, almonds, lemons, oranges, pomegranates, and many others. There is also flax, and hemp, but little timber. The emperor is absolute, his will being a law, and he often exercises great cruelties. His naval force consists chiefly of rovers, who now and then take large prizes. He can bring 100,000 men into the field, nearly half of which are horse; but the whole are poorly armed, and know little of the art of war.

MOROCCO, a city of Africa, and capital of the empire so called, situated in a pleasant plain, planted with palm-trees, having Mount Atlas to the east. The city of Morocco itself, exposed to the devastations of different conquerors, has preserved nothing but its form. The extent of the walls, which still exist entire, except in some few places, supposes a city which might contain 300,000 souls: at present this capital is little better than a desert. The ruins of houses, heaped one upon another, serve only to harbour thieves, who lurk among them to rob the passengers. The quarters which have been rebuilt are considerably distant from each other; and the houses are low, dirty, and extremely inconvenient. Mr. Chenier doubts whether it contains 30,000 inhabitants, even when the court is there.

Morocco possesses several large mosques, but they have no pretensions to magnificence. Within the walls are a number of large inclosed spaces, almost entirely detached, containing gardens of orange-trees, and pavilions, in which the princes lodge. Among the number of the public edifices at Morocco we must not forget to mention the Elcaisseria, a place where stuffs and other valuable commodities are exposed to sale. At the extremity of the city of Morocco, and very near the palace, is the quarter of the Jews, inclosed by walls near two miles round, where the Jews reside, under the guard of an alcaid, to protect them from insult. This same quarter was formerly the residence of the Spanish nobles, or others of that nation, who, from discontent, or other motives, entered into the service of the kings of Morocco; and there is still a part of the city, called the quarter of Andalusia. Not less than 3000 Jewish families formerly resided here, as may be estimated by the ruins of houses and synagogues. Of this great number there at present scarcely remain 200 families, exposed to tyranny and poverty. The emperor's palace, at the extremity of the city of Morocco, fronting Mount Atlas, is a very extensive and solid building. The principal gates are Gothic arches of cut stone, embellished with ornaments in the Arabian taste. Within the walls are various courts and gardens, elegantly laid out by European gardeners. Lon. 6. 45 W. Lat. 31. 12 N.

Morocco, or Marroquin, the skin of a goat, or some other animal resembling it, dressed in sumac or galls, and coloured of any colour at pleasure; much used in book-binding, &c. The name is ordinarily derived from the kingdom of Morocco, whence it is supposed the manner of preparing these skins was first borrowed. We have Morocco skins brought from the Levant, Barbary, Spain, Flanders, and France; red, black, yellow, blue, &c. For the manner of preparing them, see Leather.

Morocco reed, in botany. See Adonis.

MORO'SE. *a.* (*morosus*, Latin.) Sour of temper; peevish; sullen (*Watts*).

MORO'SELY. *ad.* Sourly; peevishly (*Government of the Tongue*).

MORO'SENESS. *s.* (from *morose.*) Sourness; peevishness (*Watts*).

MOR'OSIS (*morosis*, μωρωσις, from μορος, folly.) See Amentia.

MORO'SITY. *s.* (*morositas*, Latin.) Moroseness; sourness; peevishness (*Clarendon*).

MORPETH, a town of England, in the county of Northumberland, situated on the north side of the river Wansbeck, though the parish is on the south side. It has a weekly market on Wednesday, said to be the largest in England for cattle, except Smithfield. It is governed by two bailiffs, aldermen, &c. and sends two members to the British parliament. In the reign of king John, the town was burned by the inhabitants, out of hatred to that monarch. It had anciently a castle, now in ruins: ninety-one miles S. Edinburgh, and 287 N. London. Lon. 1. 38 W. Lat. 55. 15 N.

MORPHEUS, in mythology, a minister of the god Somnus, who naturally imitated the grimaces, gestures, words, and manners of mankind. He is sometimes called the god of sleep. He is generally represented as a sleeping child of a great corpulence, and with wings. He holds a vase in one hand, and in the other are some poppies.

MORPHEW, a scurf on the face.

MORRERI (Lewis), author of the Historical Dictionary, was born at Barge-mont in Province, 1643. He learned rhetoric and philosophy at Aix, and divinity at Lyons. At 18 years of age he wrote a small piece, intitled Le Pays d'Amour, and a collection of the finest French poems intitled Doux plaisirs de la Poesie. He learned Spanish and Italian; and translated out of Spanish into French the book intitled La Perfection Chretienne de Rodriguez. He then refined the Saints Lives to the purity of the French tongue. Being ordained priest, he preached at Lyons, and undertook, when he was about 30 years of age, a new Historical Dictionary, printed at Lyons in one vol. folio, 1673. But his continual labour impaired his health; so that he died in 1680, aged 37. His second volume was published after his death; and four more volumes have since been added. He left some other works behind him.

MORRIS, in ichthyology. See Septocephalus.

Morris dancers. See Moresqe.

MO'RROW. *s.* (moꞃᵹen, Saxon.) 1. The day after the present day (*Cowley*). 2. *To* Morrow. On the day after this current day (*Prior*).

MORS, Death, one of the infernal deities, born of Night without a father. She was worshipped by the ancients with great solemnity. She was not represented as an actually existing power, but as an imaginary being. Euripides introduces her in one of his tragedies on the stage. The moderns represent her as a skeleton armed with a scythe and a scymetar.

MORSE, in mastiology. See Trichecus.

MO'RSEL. *s.* (*morsellus*, low Latin.) 1. A piece fit for the mouth; a mouthful (*Shakspeare*). 2. A piece; a meal (*L'Estrange*). 3. A small quantity: not proper (*Boyle*).

MO'RSURE. *s.* (*morsure*, Fr. *morsura*, Lat.) The act of biting.

MORT. *s.* (*morte*, French.) 1. A tune sounded at the death of the game (*Shakspeare*). 2. (*morgt*, Islandic.) A great quantity.

MORTAGNE, a town of France, in the department of Orne, famous for its serges and tanneries. It is 19 miles east of Seez, and 70 west of Paris. Lon. 0. 40 E. Lat. 48. 33 N.

Mortagne, a town of France, in the department of the North, seated at the confluence of the Scarpe and Scheldt, eight miles S. E. of Tournay. Lon. 3. 30 E. Lat. 50. 29 N.

MORTAIN, a town of France, in the department of the Channel, seated on the rivulet Lances, almost surrounded by craggy rocks, 20 miles east of Avranches. Lon. 0. 54 W. Lat. 48. 37 N.

MO'RTAL. *a.* (*mortalis*, Latin.) 1. Subject to death; doomed sometime to die. 2. Deadly; destructive (*Bacon*). 3. Bringing death (*Pope*). 4. Human; belonging to man (*Milton*). 5. Extreme; violent (*Dryden*).

Mo'rtal. *s.* Man; human being (*Tickel*).

MORTA'LITY. *s.* (from *mortal.*) 1. Subjection to death; state of a being subject to death (*Watts*). 2. Death (*Shakspeare*). 3. Power of destruction (*Shakspeare*). 4. Frequency of death (*Graunt*). 5. Human nature (*Pope*).

Mortality (Bills of), are accounts or registers specifying the numbers born, married, and buried in any parish, town, or district. In general they contain only these numbers; and, even when thus limited, are of great use, by showing the degrees of healthiness and prolificness, and the progress of population in the places where they are kept. It is therefore much to be wished, that such accounts had been always correctly kept in every kingdom, and regularly published at the end of every year. We should then have had under our inspection the comparative strength of every kingdom, as far as it depends on the number of inhabitants, and its increase or decrease at different periods. But such accounts are rendered more useful, when they include the ages of the dead, and the distempers of which they have died. In this case they convey some of the most important instructions, by furnishing us with the means of ascertaining the law which governs the waste of human life, the values of annuities dependent on the continuance of any lives, on any survivorships between them, and the favourableness or unfavourableness of different situations to the duration of human life. There are but few registers of this kind; nor has this subject, though so interesting to mankind, ever engaged much attention till lately. Celebrated bills containing the ages of the dead are those for the town of Breslaw in Silesia. It is well known what use has been made of these by Dr. Halley, and after him by De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr. Halley, has been published in the Philosophical Transactions, (see the abridgement, vol. iii. p. 669.) and is the first table of this sort that has been ever published. Since the publication of this table, similar bills have been established in a few towns of this kingdom; and particularly in London, in the year 1728, and at Northampton, in 1735. See Life.

Two improvements of these registers have been proposed: the first is, that the sexes of all that die in every period of life should be specified in them, under the denomination of boys, married men, widowers, and bachelors; and of girls, married women, widows, and virgins. The second is, that they should specify the numbers of both sexes dying of every distemper in every month, and at every age. See the end of the 4th essay in Dr. Price's treatise on reversionary payments. Registers of mortality thus improved, when compared with records of the seasons, and with the circumstances that discriminate different situations, might contribute greatly to the increase of medical knowledge; and they would afford the necessary data for determining the difference between the duration of human life among males and females.

The establishment of bills of mortality in Great Britain originated in the frequent appearance of the plague, which formerly made great devastations in this country, and an abstract of the number of deaths was published weekly, to shew the increase or decrease of the disorder, that individuals might not be exposed to unfounded alarms, but have some means of judging of the necessity of removal, or of taking other precautions, and government be informed of the propriety or success of any public measures relating to the disorder. Since the disappearance of the plague, these registers have been continued from the convenience found in ascertaining by them the precise time of the birth or death of individuals, and for the information they furnish respecting the rate of human mortality, and the state of population.

The first directions for keeping parish registers of births and burials were given in 1538, when Thomas Cromwell was appointed the king's vicegerent for ecclesiastical jurisdiction, and in that capacity issued certain injunctions to the clergy, one of which ordains, that every officiating minister shall, for every church, keep a book, wherein he shall register every marriage, christening, and burial; and the injunction goes on to direct the manner and time of making the entries in the register book weekly, any neglect of which is made penal In 1547 all episcopal authority was suspended for a time, while the ecclesiastical visitors then appointed went through the several dioceses to enforce divers injunctions, among which was that respecting parish registers. This injunction was again repeated in the beginning of the reign of Elizabeth, who also appointed a protestation to be made by the clergy, in which, among other things, they promised to keep the register-book in a proper manner. One of the canons of the church of England prescribes very minutely in what manner entries are to be made in the parish registers, and orders an attested copy of the register of each successive year to be annually transmitted to the bishop of the diocese to be preserved in the bishop's registry. This canon also contains a retrospective clause, appointing that the ancient registers, so far as they could be procured, but especially since the beginning of the reign of Elizabeth, should be copied into a parchment book, to be provided by every parish; which regulation was so well obeyed, that most of the ancient parish registers now extant commence with that queen's reign, and some of them earlier, quite as far back as the date of the original injunction.

The London bills of mortality are founded upon the reports of the sworn searchers, who view the body after decease, and deliver their report to the parish clerk. The parish clerks are required, under a penalty for neglect, to make a weekly return of burials, with the age and disease of which the person died; a summary of which account is published weekly; and on the Thursday before Christmas-day, a general account is made up for the whole year. These general accounts of christenings and burials taken by the company of parish clerks of London were began December 21, 1592; and in 1594 the weekly account was first made public, as also the general or yearly account, until December 18, 1595, when they were discontinued upon the ceasing of the plague; in 1603 they were resumed, and have been regularly continued ever since. The original bills comprehended only 109 parishes, but several others were afterwards included, and in 1660 the bills were new modelled, the twelve parishes in Middlesex and Surry being made a division by themselves, as were likewise the five parishes in the city and liberties of Westminster. Several other parishes have been added to them at subsequent periods, but many of them have been merely new parishes formed out of larger ones which were before included, and the total number of parishes now comprehended in the London bills of mortality is 146. They are divided into the ninety-seven parishes within the walls, sixteen parishes without the walls, twenty-three out-parishes in Middlesex and Surry, and ten parishes in the city and liberties of Westminster. They give the ages at which the persons die, and a list of the diseases and casualties by which their death was occasioned; but little dependence can be placed on the list of diseases, except with respect to some of the most common and determinate.

From the last bill of mortality for the year, from Dec. 11, 1809, to Dec. 11, 1810, we learn that in

	Christened.	Buried.
The 97 parishes within the walls - - - -	1004	1388
17 parishes without the walls - - - -	4258	4129
23 out parishes - - - - - -	10,503	9535
10 parishes in Westminster - - - - -	4165	4841

Diseases and casualties this year.

Abortive and stillborn	574	Head-ach	1

Thirty and forty	1788	A hundred and five	1
Forty and fifty	2018		

Increased in the burials this year 3213.

These bills would afford the means of ascertaining the state of population with sufficient precision, if the proportion of annual deaths to the number of the living could be accurately determined. This, however, previous to the enumeration of 1801, could not be easily found even in the metropolis, the population of which, as deduced from the bills of mortality, was very differently stated by different writers. Mr. John Graunt, who first published observations on the London bills of mortality in the year 1662, made the proportion dying annually about 1 in 27; sir William Petty and Dr Brakenridge afterwards stated it as 1 in 30, and Mr. Maitland 1 in 24½; but Dr. Price, who bestowed much attention on this subject, has shewn that about the year 1769, at least 1 in 22½ of all the inhabitants of London died annually. In fact the proportion appears to have varied considerably at different periods, and of late years, in consequence of the houses being less crowded with inhabitants, the widening of streets, and other improvements, the metropolis has become more healthy, and consequently the proportion dying annually less than formerly. In the Observations on the Results of the Population Act, it is stated that the proportion of annual deaths in London in the year 1750 appears to have been 1 in 23, and in the year 1801 only 1 in 31.

The following statement of the average of each five years from 1730 will shew a considerable decrease in the annual number of burials, and an increase of the christenings, which strongly indicate the progressive increase of the population of the metropolis; the proportion of annual deaths to 100 christenings likewise shews that they have approached so nearly to an equality, that the population of London can now nearly support itself without an annual supply from the country.

5 Years ending	Burials.	Christenings.	Proportion to 100 Christen.
1735	25,490	17,517	145
1740	27,494	16,144	170
1745	25,350	14,419	175
1750	25,352	14,496	174
1755	21,080	15,119	139

1790	19,657	18,465	106
1795	20,228	18,800	107
1800	19,131	18,708	102

The bills of mortality in many parts of Great Britain are known to be materially defective; the deficiencies are ascribed chiefly to the following circumstances. 1. Many congregations of dissenters inhabiting towns have their own peculiar burying grounds; as have likewise the Jews, and the Roman Catholics who reside in London. 2. Some persons, from motives of poverty or convenience, inter their dead without any religious ceremony; this is known to happen in the metropolis, in Bristol, and Newcastle-upon-Tyne, and may happen in a few other large towns. 3. Children who die before baptism are interred without any religious ceremony, and consequently are not registered. 4. Many persons employed in the army and in navigation die abroad, and consequently their burials remain unregistered. 5. Negligence may be supposed to cause some omissions in the registers, especially in those small benefices where the officiating minister is not resident. Whatever may be the total number of deaths and burials, which from these several circumstances are not brought to account, it has been estimated that about 5000 of them may be attributed to the metropolis, and a large portion of the rest may be ascribed to the other great towns, and to Wales, where the registers are less carefully kept than in England. In Scotland registers of mortality have not yet been generally established; and those which are kept are in many instances very incomplete.

The total annual amount of burials, as collected pursuant to the population act, authorizes a satisfactory inference of diminishing mortality in England since the year 1780; the number of marriages and baptisms indicates that the existing population of 1801, was to that of 1780, as 117 to 100, while the amount of registered burials remained stationary during the same period, as will be seen in the following account.

Total number of burials in England and Wales.

Years.	Males.	Females.	Total.
1700	65,752	66,976	132,728
1710	70,606	69,702	140,308
1720	81,156	79,268	160,424
1730	89,085	87,408	176,493
1740	83,706	83,267	166,973
1750	77,149	77,537	154,686
1760	77,750	77,887	155,637
1770	85,952	88,431	174,383
1780	95,845	95,891	191,736
1781	94,505	94,867	189,372
1782	90,189	90,725	180,914
1783	90,606	91,383	181,989
1784	92,851	95,070	187,921
1785	91,548	93,922	185,470
1786	88,330	90,728	179,058
1787	88,123	90,595	178,718
1788	89,227	92,118	181,345
1789	88,411	90,973	179,384
1790	87,954	90,777	178,731
1791	90,895	89,557	180,452
1792	90,963	91,646	182,609
1793	98,560	98,305	196,865
1794	95,511	95,638	191,149
1795	102,086	101,242	203,328
1796	92,289	92,245	184,534
1797	92,292	92,637	184,929
1798	90,657	90,656	181,313
1799	92,078	91,189	183,267
1800	101,686	99,442	201,128

Total number of baptisms and of burials in the twenty-nine years above specified.

	Males.	Females.	Total.
Baptisms	3,285,188	3,150,922	6,436,110
Burials	2,575,762	2,590,082	5,165,844

The proportion of births, therefore, appears to be 104¼ males to 100 females; of the deaths 99½ males to 100 females. The average number of burials during the last twenty-one years was about 186,000 per annum. See Life.

MO'RTALLY. *ad.* (from *mortal.*) 1. Irrecoverably; to death (*Dryden*). 2. Extremely; to extremity (*Granville*).

MO'RTAR. *s.* (*mortarium*, Latin.) 1. A vessel in which materials are broken by being pounded with a pestle (*Ray*). 2. A short wide cannon out of which bombs are thrown (*Granville*).

Mortar. *s.* (*morter*, Dutch; *mortier*, Fr.) Cement made of lime and sand with water, and used to join stones or bricks (*Mortimer*).

The proportions of lime and sand usually employed in making the common mortar, are two parts of the former to three of the latter, which are mixed up with soft water; but its quality and durability will, according to Dr. Anderson, be considerably improved, if the lime be slaked, and the sand mixed up with lime-water, instead of the common. The reason assigned for this opinion is, that the fluid drawn from wells contains a large portion of fixed air; which, by mingling with the mortar, before it is used, reduces the quick-lime into a kind of inert calcareous earth, similar to chalk, and thus spoils the cement. But, if the mortar be worked up in a perfectly caustic state, it attracts the air so slowly, that it concretes into a kind of stony matter, which, in the course of time, becomes as hard as the rock from which the lime-stone was taken.

In the year 1777 was published (in French), an ingenious Inquiry concerning the Manner in which the Romans prepared the Lime they used in Building; as also on their Method of mixing and using their Mortar; by M. de Lafaye. The principal circumstance appears to be the mode of slaking the lime without liquefying it, so as to reduce it to powder; and at the same time to leave it sufficiently caustic to yield to strong mortar; which, in proportion to its age, will acquire additional strength.—To effect such object, it is requisite to select good fresh lime, made of hard lime-stone, which is to be broken into pieces of the size of an egg. These should be placed in a shallow open basket, which ought to be plunged into water till the surface of the fluid begin to boil. The basket is then drawn out, and suffered to drain for a short time; after which the lime is put into casks, where it speedily grows hot, and crumbles into powder.

The lime thus prepared is to be mixed with various compositions of mortar, according to the purposes for which they are designed. It may be preserved for a considerable time, and will retain its useful properties by simply covering the casks with straw. M. Guyton de Morveau states, in a late volume of the Annales de Chimie, that he employed this lime, 18 years since, in the construction of a small aqueduct, which was intended to convey water to an artificial nitre-bed. The mortar consisted of equal parts of the following three ingredients, namely, sand, fragments of calcareous stone, and lime slaked according to the directions above given: in a short time it acquired an uncommon degree of firmness, which has remained unimpaired since that period.

This chemist has likewise given the following proportions for good mortar:

Fine sand - - -	30
Cement of well-baked bricks -	30
Slaked lime - - -	20
Unslaked lime - - -	20
	100

Mortar, a chemical utensil very useful for the division of bodies, partly by percussion and partly by grinding. Mortars have the form of an inverted bell. The matter intended to be pounded is to be put into them, and there it is to be struck and bruised by a long instrument called a pestle. The motion given to the pestle ought to vary according to the nature of the substances to be pounded. Those which are easily broken, or which are apt to fly out of the mortar, or which are hardened by the stroke of the pestle, require that this instrument should be moved circularly, rather by grinding or bruising than by striking. Those substances which are softened by the heat occasioned by rubbing and percussion, require to be pounded very slowly. Lastly, those which are very hard, and which are not capable of being softened, are easily pounded by repeated strokes of the pestle. They require no bruising but when they are brought to a certain degree of fineness. But these things are better learned by habit and practice than by any directions.

As mortars are instruments which are constantly used in chemistry, they ought to be kept of all sizes and materials; as of marble, copper, glass, iron, gritstone, and agate. The nature of the substance to be pounded determines the choice of the kind of mortar. The hardness and dissolving power of that substance are particularly to be attended to. As copper is a soft metal, soluble by almost all menstruums, and hurtful to health, good artists have some time ago proscribed the use of this metal.

One of the principal inconveniences of pulverisation in a mortar proceeds from the fine powder which rises abundantly from some substances during the operation. If these substances be precious, the loss will be considerable; and if they be injurious to health, they may hurt the operator. These inconveniences may be remedied, either by covering the mortar with a skin, in the middle of which is a hole, through which the pestle passes; or by moistening the matter with a little water when this addition does not injure it; or, lastly, by covering the mouth and nose of the operator with a fine cloth, to exclude this powder. Some substances, as corrosive sublimate, arsenic, calxes of lead, cantharides, euphorbium, &c. are so noxious that all these precautions ought to be used, particularly when a large quantity of them is pounded.

Large mortars ought to be fixed upon a block of wood so high that the mortar shall be level with the middle of the operator. When the pestle is large and heavy, it ought to be suspended by a cord or chain fixed to a moveable pole, placed horizontally above the mortar: this pole considerably relieves the operator, because its elasticity assists the raising of the pestle.

Mortar-piece, in the military art, a short piece of ordinance, thick and wide, proper for throwing bombs, carcases, shells, stones, bags filled with grape-shot, &c. See **Gunnery.**

Mortars (Land), are those used in sieges, and of late in battles, mounted on beds made of solid timber, consisting generally of four pieces, those of the royal and cohorn excepted, which are but one single block; and both mortar and bed are transported on block-carriages. There is likewise a kind of land-mortars mounted on travelling carriages, invented by count Buckeburg, which may be elevated to any degree; whereas ours are fixed to an angle of 45 degrees, and firmly lashed with ropes. The following table shows the weight of land-mortars and shells; together with the quantity of powder the chambers hold when full; the weight of the shells, and powder for loading them.

Diameter of mortars.	13-inch.	10-inch.	8-inch.	5-8 inch royal.	4-6 inch cohorn.

Mortars (Sea), are those which are fixed in the bomb-vessels for bombarding of places by sea: and as they are generally fired at a much greater distance than that which is required by land, they are made somewhat longer and much heavier than the land-mortars. The following table exhibits the weight of the sea-mortars and shells, and also of their full charges.

Nature of the mortar.	Powder contained in the chamber when full.	Weight of the mortar.	Weight of the shell when fixed.	Weight of powder contained in the shell.
	lb. oz.	C. qr. lb.	lb.	lb. oz.
10-inch howitzer.	12 0	31 2 26		
13-inch mortar.	30 0	81 2 1	198	7 0
10-inch mortar.	12 0	34 2 11	93	

To charge or load a Mortar, the proper quantity of gun-powder is put into the chamber, and if there be any vacant space they fill it up with hay: some choose a wooden plug; over this they lay a turf, some a wooden tampion fitted to the bore of the piece; and lastly the bomb; taking care that the fuse be in the axis thereof, and the orifice be turned from the muzzle of the piece: what space remains is to be filled up with hay, straw, turf, &c. so as the load may not be exploded without the utmost violence.

The quantity of gun-powder to be used is found by dividing the weight of the bomb by 30; though this rule is not always to be strictly observed.

When the proper quantity of powder necessary to charge a sea-mortar is put into the chamber, it is covered with a wad well beat down with the rammer. After this the fixed shell is placed upon the wad, as near the middle of the mortar as possible, with the fuse-hole uppermost, and another wad pressed down close upon it, so as to keep the shell firm in its position. The officer then points the mortar according to the proposed inclination. When the mortar is thus fixed, the fuse is opened; the priming-iron is also thrust into the touch-hole of the mortar to clear it, after which it is primed with the finest powder. This done, two of the matrosses or sailors, taking each one of the matches, the first lights the fuse, and the other fires the mortar. The bomb, thrown out by the explosion of the powder, is carried to the place intended: and the fuse, which ought to be exhausted at the instant of the shell's falling, inflames the powder contained in it, and bursts the shell in splinters; which, flying off circularly, occasion incredible mischief wheresoever they reach.

If the service of mortars should render it necessary to use pound-shots, 200 of them with a wooden bottom are to be put into the 13-inch mortar, and a quantity of powder not exceeding 5 pounds; and 100 of the above shot with 2½ pounds of powder, for the 10-inch mortar, or three pounds at most.

To elevate the Mortar, so as its axis may make any given angle with the horizon, they apply the artillery-level or gunner's quadrant. An elevation of 70 or 80 degrees is what is commonly chosen for rendering mortars most serviceable in casting shells into towns, forts, &c. though the greatest range be at 45 degrees.

All the English mortars are fixed to an angle of 45 degrees, and lashed strongly with ropes at that elevation. Although in a siege there is only one case in which shells should be thrown with an angle of 45 degrees; that is, when the battery is so far off that they cannot otherwise reach the works: for when shells are thrown out of the trenches into the works of a fortification, or from the town into the trenches, they should have as little elevation as possible, in order to roll along, and not bury themselves; whereby the damage they do, and the terror they occasion, are much greater than if they sink into the ground. On the contrary, when shells are thrown upon magazines or any other buildings with an intention to destroy them, the mortars should be elevated as high as possible, that the shells may acquire a greater force in their fall, and consequently do greater execution.

If all mortar pieces were, as they ought to be, exactly similar, and their requisites of powder as the cubes of the diameters of their several bores, and if their shells, bombs, carcases, &c. were also similar; then, comparing like with like, their ranges on the plane of the horizon, under the same degree of elevation, would be equal; and consequently one piece being well proved, i. e. the range of the grenado, bomb, carcase, &c. being found to any degree of elevation, the whole work of the mortar-piece would become very easy and exact.

But since mortars are not thus similar, it is required that the range of the piece, at some known degree of elevation, be accurately found by measuring; and from hence all the other ranges may be determined.

Thus, to find the range of the piece at any other elevation required: say, As the sine of double the angle under which the experiment was made, is to the sine of double the angle proposed, so is the range known to the range required.

MORTARA, a strong town of Italy, in the Milanese, subject to the king of Sardinia. It is 15 miles N.E. of Casal, and 22 S.W. of Milan. Lon. 8. 40 E. Lat. 45. 22 N.

MORTGAGE, in law, an obligation, whereby lands or tenements of a debtor are pawned or bound over to the creditor for money, or other effects borrowed; peremptorily to be the creditor's for ever, if the money be not repaid at the day agreed on.

In this sense, *mortgage*, in the common law, amounts to much the same with *hypotheca*, in the civil law.

The creditor holding such land, on such agreement, is in the mean time called tenant at mortgage. He who lays the pawn or gage is called the mortgager; and he that takes it the mortgagee. If a mortgage include excessive usury, it is prohibited by a statute 37 Hen. VIII.

The French sometimes use the word mortgage in the same sense in their language, where it stands in contradistinction to a simple contract, which does not carry with it the mean profits, and which they call *vif-gage*, life-pledge.

Glanville defines mortgage, *mortuum vadium*, to be that *cujus fructus vel reditus interim percepti in nullo se acquietant*. Thus, it is called mortgage, i. e. dead gage, of *mort*, death, and *gage*, pledge; because whatever profit it yields, yet it redeems not itself by yielding such profit, except the whole sum borrowed be likewise paid at the day; the mortgager being by covenant to receive the profits till default of payment. Others hold it called mortgage, because, if the money be not paid at the day, the land, *moritur*, dies to the debtor, and is forfeited to the creditor.

The last and best improvement of mortgages seems to be, that in the mortgage-deed of a term for years, or in the assignment thereof, the mortgageor should covenant for himself and his heirs, that if default is made in the payment of the money at the day, then he and his heirs will, at the costs of the mortgagee and his heirs, convey the freehold and inheritance of the mortgaged lands to the mortgagee and his heirs, or to such person or persons (to prevent merger of the term) as he or they shall direct and appoint. for the reversion, after a term of fifty or a hundred years, being little worth, and yet the mortgagee for want thereof continuing but a termer, and subject to a forfeiture, &c. and not capable of the privileges of a freeholder; therefore when the mortgageor cannot redeem the land, it is but reasonable the mortgagee should have the whole interest and inheritance of it to dispose of it as absolute owner. 3 Bac. Abr. 633.

Although after breach of the condition, an absolute fee-sipmle is vested at common law in the mortgagee; yet a right of redemption being still inherent in the land, till the equity of redemption is foreclosed, the same right shall descend to, and is invested in, such persons as had a right to the land, in case there had been no mortgage or incumbrance whatsoever; and as an equitable performance as effectually defeats the interests of the mortgage as the legal performance does at common law, the condition still hanging over the estate till the equity is totally foreclosed; on this foundation it has been held that a person who comes in under a voluntary conveyance may redeem a mortgage; and though such right of redemption is inherent in the land, yet the party claiming the benefit of it must not only set forth such right, but also shew that he is the person entitled to it. Hard. 465.

But if a mortgage is forfeited, and thereby the estate absolutely vested in the mortgagee at common law, yet a court of equity will consider the real value of the tenements, compared with the sum borrowed. And if the estate is of greater value than the sum lent thereon, they will allow the mortgageor, at any reasonable time, to recal or redeem the estate, paying to the mortgagee his principal, interest, and costs. This reasonable advantage, allowed to the mortgageors, is called the equity of redemption. 2 Black. 159.

It is a rule established in equity, analogous to the statute of limitation, that after twenty years possession of the mortgagee he shall not be disturbed, unless there are extraordinary circumstances; as in the case of femes covert, infants, and the like. 3 Atk. 313.

Where a mortgage is made, the mortgagee should have the title deeds, as under some circumstances it has been held in equity that a subsequent mortgagee who has the title deeds of the mortgageor shall have a prior claim. A third mortgagee also who buys up the first mortgagee will be preferred to the second, if he had no notice of the second. By stat. 7 Geo. II. c. 20, where an action is brought to recover money due on mortgage, or an ejectment to get into the possession of the lands, if the defendant appears, and within six months pays the debt, interest, and costs, the writ shall be staid. And where a bill is filed in equity by the mortgagee to compel the mortgageor either to pay off the mortgage, or be foreclosed, or prevented from having his equity of redemption, the like time is allowed, and afterwards the estate is absolutely foreclosed. But the act does not extend to cases where the mortgager disputes the validity or fairness of the mortgage. By stat. 14 Geo. III. c. 79, sect. 2, estates in the West Indies may be mortgaged here at West-India interest. A remainder man may force the tenant in tail to keep down the interest, but not to redeem a mortgage.

To Mo'rtgage. *v. a.* To pledge; to put to pledge (*Arbuthnot*).

Mortgage'e. *s.* (from *mortgage.*) He that takes or receives a mortgage (*Temple*).

MO'RTGAGER. *s.* (from *mortgage.*) He that gives a mortgage.

MORTI'FEROUS. *a.* (*mortifer*, Lat.) Fatal; deadly; destructive (*Hammond*).

MORTIFICA'TION. *s.* (*mortification*, French.) 1. The state of corrupting, or losing the vital qualities; gangrene. (See Gangrene.) 2. Destruction of active qualities (*Bacon*). 3. The act of subduing the body by hardships and macerations (*Arbuthnot*). 4. Humiliation; subjection of the passions. 5. Vexation; trouble (*L'Estrange*).

To MO'RTIFY. *v. a.* (*mortifier*, French.) 1. To destroy vital qualities. 2. To destroy active powers, or essential qualities (*Bacon*). 3. To subdue inordinate passions (*Shakspeare*). 4. To macerate or harass the body to compliance with the mind (*Brown*). 5. To humble; to depress; to vex (*Addison*).

To Mo'rtify. *v. n.* 1. To gangrene; to corrupt (*Bacon*). 2. To be subdued; to die away. 3. To practise religious severities (*Law*).

MORTIMER (John Hamilton), an English painter, was born at East Bourne, in Sussex, in 1739. He received his first instructions from his uncle, who was an itinerant painter; but afterwards he became a pupil of Hudson, and for some months resided with sir Joshua Reynolds. When the society for the encouragement of arts gave premiums for historical pictures, Mortimer carried away the prize of 100 guineas for a piece representing St. Paul converting the Britons. In 1779, he was appointed by his majesty a royal academician, without any solicitation; but that honour was hardly enjoyed by him, for he died the same year at his house in Norfolk-street.

MO'RTISE. *s.* (*mortaise*, Fr.) A hole cut into wood that another piece may be put into it and form a joint (*Shakspeare*).

To Mo'rtise. *v. a.* To cut to a mortise; to join with a mortise (*Drayton*).

MORTLAKE, a village in Surrey, seated on the Thames, six miles west of London. Great part of this parish is inclosed in Richmond Park; and his majesty has a farm here of 80 acres in his own occupation.

MORTLICH, a village in Banffshire, six miles S.W. of Keith. Here Malcolm II. in memory of a victory gained over the Danes, founded a bishopric, which was translated to Aberdeen by David I.

MORTMAIN, signifies an alienation of lands and tenements to any corporation, and their successors, as bishops, parsons, vicars, &c. which is restrained in Magna Charta, and cannot be done without the king's licence. The disposing of property to hospitals is allowed by 35 Eliz. c. 5, and various enactments have been made to prevent the influence of priests and crafty men from taking advantage of the last hours of the lives of weak devotees, by obtaining gifts in mortmain or perpetuity. The chief of these is the stat. 9 Geo. II. c. 36. (called the statute of mortmain) that no manors, lands, tenements, rents, advowsons, or other hereditaments, corporeal, or incorporeal, whatsoever, nor any sum or sums of money, goods, chattels, stocks in the public funds, securities for money, or other personal estate whatsoever, to be laid out or disposed of in the purchase of any lands, tenements, or hereditaments, shall be given, limited, or appointed by will, to any person or persons, bodies politic or corporate, or otherwise, for any estate or interest whatsoever, or any ways charged or incumbered by any person or persons whatsoever, in trust, or for the benefit of any charitable use whatsoever; but such gift shall be by deed, indented, sealed, and delivered in the presence of two or more credible witnesses, twelve calendar months at least before the death of such donor, and be inrolled in the high court of chancery within six calendar months after execution, and the same to take effect immediately after the execution for the charitable use intended, and be without any power of revocation, reservation, on trust for benefit of the donor. And by the fourth section all gifts or incumbrances otherwise made are void. This act however does not extend to prevent the making bequests, merely of money, to charitable uses.

MORTON (Thomas), a learned English bishop, was born at York in 1564, and educated at St. John's college, Cambridge, where he was chosen fellow. In 1603 he attended lord Eure, ambassador to the emperor of Germany, as his chaplain, and in 1607 was appointed dean of Gloucester. In 1609 he was made dean of Winchester, and in 1615 advanced to the see of Chester; from whence he was translated to Lichfield and Coventry in 1618. In 1632 he was removed to Durham. He suffered many hardships in the great rebellion, notwithstanding his age and exemplary character. He died in 1659. This worthy bishop has some small pieces in print.

Morton (James earl of), regent of Scotland, was born at Dalkeith in 1530, and educated under the famous Buchanan at Paris. He returned to Scotland in 1554, and greatly promoted the reformation; but having been accused of the murder of lord Darnley, he fled to England. Afterwards he returned home, and was made chancellor of Scotland. In 1574 he succeeded the earl of Mar as regent, but resigned in 1579. He was condemned for high treason in 1581, and beheaded by a machine which he brought himself from England for the accommodation of his enemies, somewhat similar to the guillotine of France.

Morton (William), a counsellor, who in the reign of Charles I. entered into the king's army, and became a lieutenant-colonel. In 1663 he was made a serjeant at law; and in 1665 a judge in the court of king's bench.

Morton (John), archbishop of Canterbury, was a native of Dorchester, and became so eminent for his skill in jurisprudence, that Henry VI. and Edward IV. both made him a privy counsellor. He was also raised to the see of Ely, and lastly to the metropolitical seat of Canterbury. Henry VII. appointed him chancellor, and obtained for him a cardinal's hat. He died in 1500. (*Watkins*).

Morton, or Morton Hampstead, a town in Devonshire, with a noted market for yarn on Saturday. It is seated on a hill near Dartmoor, 14 miles S.W. of Exeter, and 185 W. by S. of London. Lon. 3. 46 W. Lat. 50. 39 N.

Morton, or Morton in Marsh, a town in Gloucestershire, with a market on Tuesday, seated on a fossway, 29 miles E.S.E. of Worcester, and 83 W.N.W. of London. Lon. 1. 36 W. Lat. 52. 0 N.

MO'RTPAY. *s.* (*mort* and *pay.*) Dead pay; payment not made (*Bacon*).

MO'RTRESS. *s.* A dish of meat of various kinds beaten together (*Bacon*).

MORTUARY, in law, is a sort of ecclesiastical heriot (see Heriot), being a customary gift claimed by and due to the minister in very many parishes on the death of his parishioners. They seem originally to have been only a voluntary bequest to the church; being intended, as Lyndewode informs us from a constitution of archbishop Langham, as a kind of expiation and amends to the clergy for the personal tithes, and other ecclesiastical duties, which the laity in their life-time might have neglected or forgotten to pay. For this purpose, after the lord's heriot or best good was taken out, the second best chattel was reserved to the church as a mortuary. And therefore in the laws of king Canute, this mortuary is called soul scot, or *symbolum animæ*. And, in pursuance of the same principle, by the laws of Venice, where no personal tithes have been paid during the life of the party, they are paid at his death out of his merchandise, jewels, and other moveables. So also, by a similar policy in France, every man that died without bequeathing a part of his estate to the church, which was called dying without confession, was formerly deprived of christian burial; or, if he died intestate, the relations of the deceased, jointly with the bishop, named proper arbitrators to determine what he ought to have given to the church in case he had made a will. But the parliament, in 1409, redressed this grievance.

It was anciently usual in England to bring the mortuary to church along with the corpse when it came to be buried; and thence it is sometimes called a corse-present: a term which bespeaks it to have been once a voluntary donation. However in Bracton's time, so early as Henry III. we find it rivetted into an established custom: insomuch that the bequests of heriots and mortuaries were held to be necessary ingredients in every testament of chattels. *Imprimis autem debet quilibet, qui testamentum fecerit, dominum suum de meliori re quam habuerit recognoscere; et postea ecclesiam de alia meliori:* the lord must have the best good left him as an heriot: and the church the second best as a mortuary. But yet this custom was different in different places: *in quibusdam locis habet ecclesia melius animal de consuetudine; in quibusdam secundum, vel tertium melius; et in quibusdam nihil: et ideo consideranda est consuetudo loci.* This custom still varies in different places, not only as to the mortuary to be paid, but the person to whom it is payable. In Wales a mortuary or corse-present was due upon the death of every clergyman to the bishop of the diocess; till abolished, upon a recompence given to the bishop, by the statute 12 Ann. st. 2. c. 6. And in the archdeaconry of Chester a custom also prevailed, that the bishop, who is also archdeacon, should have at the death of every clergyman dying therein his best horse or mare, bridle, saddle, and spurs; his best gown or cloak, hat, upper garment under his gown, and tippet, and also his best signet or ring. But by statute 28 Geo. II. c. 6. this mortuary is directed to cease, and the act has settled upon the bishop an equivalent in its room. The king's claim to many goods, on the death of all prelates in England, seems to be of the same nature; though sir Edward Coke apprehends that this is a duty upon death, and not a mortuary: a distinction which seems to be without a difference. For not only the king's ecclesiastical character, as supreme ordinary, but also the species of the goods claimed, which bear so near a resemblance to those in the archdeaconry of Chester, which was an acknowledged mortuary, puts the matter out of dispute. The king, according to the record vouched by sir Edward Coke, is entitled to six things; the bishop's best horse or palfrey, with his furniture; his cloak or gown, and tippet; his cup and cover; his bason and ewer; his gold ring; and lastly, his *muta canum*, his mew or kennel of hounds.

This variety of customs with regard to mortuaries giving frequently a handle to exactions on the one side, and frauds or expensive litigations on the other, it was thought proper by statute 21 Hen. VIII. c. 6. to reduce them to some kind of certainty. For this purpose it is enacted, that all mortuaries, or corse-presents to parsons of any parish, shall be taken in the following manner, unless where by custom less or none at all is due: viz. for every person who does not leave goods to the value of ten marks, nothing: for every person who leaves goods to the value of ten marks and under 30 pounds, 3*s.* 4*d.*; if above 30 pounds, and under 40 pounds, 6*s.* 8*d.*; if above 40 pounds, of what value soever they may be, 10*s.* and no more. And no mortuary shall throughout the kingdom be paid for the death of any feme-covert; nor for any child; nor for any one of full age, that is not a house-keeper; nor for any wayfaring man; but such wayfaring man's mortuary shall be paid in the parish to which he belongs. And upon this statute stands the law of mortuaries to this day.

MORVAUNT, in mastiology. See Ovis.

MORUS. Mulberry. In botany, a genus of the class monœcia, order tetrandria. Male: calyx four-parted, corolless. Fem.: calyx four-leaved; corolless; styles two; calyx becoming a berry; seed one. Seven species, as follows:

1. M. nigra, common mulberry; a native of Italy.
2. M. alba, white mulberry; a native of China.
3. M. papyrifera, paper mulberry tree; a native of Japan.
4. M. rubra, red-mulberry tree; a native of Virginia.
5. M. Indica, Indian mulberry; a native of the East Indies.
6. M. tinctoria, dyer's mulberry, or fustick-wood; a native of America.
7. M. Tatarica, Tartarian mulberry; a native of Siberia and Russia.

Of these three only are cultivated in our own gardens; the white, the black, and the paper mulberry.

The white mulberry is commonly planted in the south of Europe for its leaves as a food for the silk-worm (*phalæna mori*); yet the Persians use the common black mulberry conjointly with the white for this purpose. The trees which are designed to feed silk-worms should never be suffered to grow tall, but rather be kept in a hedge-form; and their leaves, instead of being pulled off singly, should be sheered off together, and with their young branches. This sort of mulberry may be propagated from seeds or layers: the best mode is from seeds procured from the south of

France or Italy; and the best way to sow these seeds in England is to make a moderate hot-bed, which should be arched over with hoops, and covered with mats: upon this bed the seeds should be sown in the middle of March, and covered over with light earth, about a quarter of an inch deep. In very dry weather the bed should be frequently watered, and in the heat of the day shaded with mats, and also covered in cold nights. The black mulberry is common in most gardens, being planted for the delicacy of its fruit. It may be propagated by sowing the seeds, or by laying down the tender branches, which in two years will take root, and may then be transplanted to the places where they are to remain. Those plants which are propagated from seeds are commonly the most vigorous, and generally make the straightest stems: but then there is a very great hazard of their being fruitful; for it often happens that those plants for the most part are of the male kind, which produce katkins, but seldom have much fruit: but as the trees raised by layers are subject to have crooked unsightly stems, there should be care taken in the choice of straight shoots to make layers, and when they are transplanted out, they should have straight stalks fixed down by each, to which they should be fastened as the shoot is extended, until it comes to the height you design the stem: then you may suffer the branches to extend as they seem inclinable, for this tree should not be often pruned, but only such branches should be cut off which shoot cross, and bruise themselves by cutting against each other, and such as decay should also be cut off. This tree delights in a light soil, not too wet nor over dry, and should have an open exposure. The soil under this tree should also be every year well dug and manured, though scarcely any plants will grow under it.

The paper-mulberry, with palmate leaves and bristly fruit, may be propagated by laying down the branches and planting the cuttings in the manner directed for the black-mulberry. It takes its name from the use which is made of its bark by the Japanese. Yet the leaves both of this sort and of the Tartarian mulberry are used as food for the silk-worm, the former in France, and the latter very largely in China. The paper mulberry thrives best in a sandy soil, grows quicker than the black, and is not injured by the cold. M. de la Bouviere affirms, that he procured a beautiful vegetable silk from the bark of the young branches of this species of mulberry, which he cut while the tree was in sap, and afterwards beat and steeped. The women of Louisiana procure a similar material from the shoots which issue from the stock of the mulberry, and which are four or five feet high. After taking off the bark, they dry it in the sun, and then beat it, that the external part may fall off; and the internal part, which is fine bark, remains entire. This is again beaten, to to make it still finer; after which it is bleached in the dew. It is then spun, and various fabrics, such as nets and fringes, are made of it; they even sometimes weave it and manufacture it into cloth. The finest sort of cloth among the inhabitants of Otaheite and others of the South Sea islands is made of the bark of this tree.

The morus tinctoria is a fine-timber tree, and a principal ingredient in many of our yellow dyes; for which purpose it is chiefly imported into Europe. The berries are sweet and wholesome; but not much used, except by birds, who scatter them very widely, and hence largely contribute to the propagation of the plant.

MOSA (anc. geog.), a river of Belgica, rising in mount Vogesus on the borders of the Lingones, and which, after receiving a part of the Rhine called Vahalis, forms the island of the Batavia and passes off into the sea, at no greater distance than 80 miles: its mouth, which is large and broad, is that which Pliny calls Helius, denoting *lower*, according to some German writers. Now called the Maese, or Meuse; rising in Champaign, on the borders of the county of Burgundy, or the Franche Compté, at a village called Meuse, whence the appellation; and running north through Lorrain and Champaign into the Netherlands: it afterwards directs its course north-east, and then west; and joining the Waal runs to Dort, and falls into the German sea, a little below the Briel.—According to Baudrand, it twice receives the Waal; by the first junction forming the island Bommel; and again receives it at Worcum, from which place proceeding to Dort, it divides into two branches, which again uniting together form one large mouth discharging itself into the German sea.

MOSÆ PONS (anc. geog.) supposed to be Mæstricht.

MOSAIC LAW, or the LAW OF MOSES, is the most ancient that we know of in the world, and is of three kinds; the moral law, the ceremonial law, and the judicial law. The different manner in which each of these was delivered may perhaps suggest to us a right idea of their different natures. The moral law, or ten commandments, for instance, was delivered on the top of the mountain, in the face of the whole world, as being of universal influence, and obligatory on all mankind. The ceremonial was received by Moses in private in the tabernacle, as being of peculiar concern, belonging to the Jews only, and destined to cease when the tabernacle was down, and the vail of the temple rent. As to the judicial law, it was neither so publicly nor so audibly given as the moral law, nor yet so privately as the ceremonial; this kind of law being of an indifferent nature, to be observed, or not observed, as its rites suit with the place and government under which we live. The five books of Moses called the Pentateuch are frequently styled, by way of emphasis, the law. This was held by the Jews in such veneration, that they would not allow it to be laid upon the bed of any sick person, lest it should be polluted by touching the dead.

MOSAIC, or MOSAIC-WORK, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square, and cemented on a ground of stucco, in such a manner as to imitate the colours and gradations of painting. The critics are divided as to the origin and reason of the name. Some derive it from *mosaicum*, a corruption of *musaicum*, as that is of *musivum*, as it was called among the Romans. Scaliger derives it from the Greek μουσα, and imagines the name was given to this sort of works as being very fine and ingenious. Nebricensis is of opinion it was so called, because *ex illis picturis ornabanter musea.*

It is impossible to ascertain the æra of the invention; but it is by no means improbable that

It was suggested by the forming of figures in pavements with different coloured stones or marbles, the durability of which substances, and their resistance of damps, suggested the introduction of imitations of objects on walls and parts of buildings exposed to the action of the weather; those, however, probably were at first very rude and tasteless performances. The Greeks transmitted the art to the Romans: it was perpetuated in Italy, according to the Abbé Barthelemy, during the incursions of the barbarians, and brought to perfection in Rome in subsequent ages, where the works of the best masters still remain for the admiration of the present and many future generations. The fragments, which are generally of marble, and cut into cubical forms, were distributed with great skill and judgment in the most impervious cement, and being thus firmly connected, the surface received a high polish. The elegance of the work consists in the true disposition of the fragments, their diminutive size, and the richness of the colours: of the latter several of the principal were obtained from the quarries of Sicily and Greece, "at the same time that the different shades were found blended in different species of marble. The whiteness and purity of snow was emulated by the Parian; alabaster, beautifully fair by that from Synnada, in Phrygia; and unsullied ivory, by a different description from Asia Minor: the marble from Jassus, in Caria, furnished a glowing crimson; and those of Sicily, granites and rubies." The intermediate colours and gradations of colours were supplied by several means, particularly enamels, as appears from the mosaic works discovered in the Jesuit's college at Frescati, which were conveyed to the cabinet belonging to the order at Rome: in those the blue is a composition or paste; and in one of the pieces are two shades of yellow, one of which is marble, and the other brick.

There are specimens of ancient mosaic, composed exclusively of enamel, and such were those which adorned the floors and walls of a house discovered in the last century at Surrento, and which are attributed to Pollio. Among the pieces preserved at Rome, there were several that agreed with the ideas generally entertained of this laborious and durable species of ornament: but far superior were those valuable fragments found by M. Furietti in Adrian's villa at Tivoli, which he described in a work of great judgment and erudition. One of the pieces alluded to represents four doves, arranged on the rim of a vase, and is equally remarkable for the excellence of the performance, and the connection of the subject with another treated by Sosus, and taken from a house at Pergamus. "The Abbe," observes M. Furietti, "is of opinion, that Adrian had caused it to be removed to embellish his house at Tivoli; but may we not as fairly presume that the emperor was satisfied with a copy of it? An idea that would solve some difficulties found in the writings of Pliny."

The monument, however, most interesting to antiquaries, was some years past preserved at the palace of the princes of the Barbarini family at Palestrina, and is the celebrated work in mosaic which in its original destination covered the sanctuary of the temple at Preneste. This magnificent specimen of ancient skill is described by Barthelemy as being about eighteen feet in length, and rather more than fourteen in breadth; and the attributes of the hunters and animals represented on a mountainous country, in the upper part, left him no reason to doubt that the scene was intended for Egypt. Greek characters inscribed beneath the animals give their names. "In the lower part of the mosaic we perceive the Nile, winding round several small islands; boats with oars, or sails; Egyptians in pursuit of crocodiles, which conceal themselves among the rushes; rustic cottages; superb buildings; priests performing religious ceremonies in their temples; Egyptian women, reclined under a bower on the borders of a canal, with cups or musical instruments in their hands; and, lastly, a magnificent tent, near which a general, followed by several soldiers, armed with lances and shields, advances towards a female with a palm-branch in her left hand, and in her right a species of garland, which she holds out to him. It was natural," adds this learned writer, "that the sagacity of antiquaries should be employed on so rich a composition. Father Kircher discovered in it the vicissitudes of fortune; cardinal Polignac, the arrival of Alexander in Egypt; and father Montfaucon, exhibitions of the Nile, of Egypt and of Ethiopia." Barthelemy, with more probability, thought it represented the arrival of the emperor Adrian in a province of Upper Egypt.

Very few, if any, pictures in mosaic have been found in England; but numbers of pavements of Roman origin have often been, and still are continually discovered. Those necessarily differ considerably from the delicate and beautiful works already noticed; and yet the neatness of their component parts, and the elegance of their figures, obtain and deserve admiration. Of more modern performances, there are still a sufficient number remaining in our abbey and cathedral churches to prove that we have not been deficient in this branch of the arts, although no instances occur of our having adopted this method of decorating walls, which is rather singular, as prudence seems to suggest the propriety of giving stability to the performances of our artists, whose works are subject to constant damps from the humidity of the climate. Of all the pavements in mosaic left in our churches, not one can be compared with that placed by Richard Ware, abbot of St. Peter's, Westminster, before the high altar of the church, in 1272, which is thus described by Malcolm, in the first volume of Londinium Redivivum. "The materials are lapis-lazuli, jasper, porphyry, alabaster, Lydian, and serpentine marbles and touchstone. The centre of the design is a large circle, whose centre is a circular plane of porphyry, three spans and a quarter in diameter; round it stars of lapis-lazuli, pea-green, red and white, which being of most beautiful colours, have been subject to depredations; those enclosed by a band of alabaster; and without, a border of lozenges, red and green; the half lozenges contain triangles of the same colours. A dark circle held brass letters, the places of which may be seen; but are now reduced to six. The extreme lines of this great circle run into four smaller circles facing the cardinal points: that to the east, a centre of orange and green variegated; round it a circle of green and red wedges; without that, lozenges of the same colours; and completed by a dark border. To the north, the circle has a sexagon centre of variegated grey and yellow; round it a band of porphyry and a dark border. The west circle nearly similar. The south, a black centre within a variegated octagon. A large lozenge incloses all the above circles, which is formed by a double border of olive-colour; within which, on one corner only, are 138 circles intersecting each other, and each made by four oval pieces, inclosing a lozenge. The other parts vary in figure; but would take many pages to describe.

"The above lozenge has a circle on each of its sides, to the north-west, south-west, north-east, and south-east. The first contains a sexagon, divided by lozenges of green; within which are forty-one red stars. In the intersections red triangles. Green triangles form a sexagon round every intersection. The second contains a sexagon; within it seven stars of red and green, forming several sexagons, containing yellow stars. The third has a sexagon, formed by intersecting lines into sexagons and triangles; within the former stars of red and green. The latter sixteen smaller triangles of red, green, and yellow. The last a sexagon, with thirty-one within it, filled by stars of six rays, green and yellow. The spaces within the great lozenge round the circles is composed of circles, stars, squares, lozenges, and triangles, the component parts of which are thousands of pieces of the above shapes. The whole of the great lozenge and circles is inclosed by a square; the sides to the cardinal points. It has held other parts of the inscription: of this O and Є only remain on the eastern side, N O on the south, none on the west, and Є on the north. The four outsides are filled by parallelograms and circles of considerable size, all divided into figures nearly similar to those described."

The above descriptions of mosaic pictures and mosaic pavements will convey a competent idea of the nature of the art. The manner in which they are composed is explained by Keysler, whose accuracy is almost proverbial. According to this valuable author, persons were constantly employed at Rome in making copies in mosaic of those excellent pictures which adorned the walls of St. Peter's church, to replace the latter, as the damps of the building were annually and gradually destroying them. The materials used in his time were small pieces of glass, tinted with different gradations of colours, in the manner of the fine worsted used for needle-work. The glass was cast in thin plates, and afterwards cut into pieces of different lengths and breadths: some of those intended for the composition of figures to be placed on vaults and ceilings were above half an inch in width; but those used for subjects situated near the spectator were formed by pieces not thicker than a common pin, of which two millions are said to be necessary to compose a portrait four feet square. The substance prepared to receive these shreds of glass is a kind of paste, composed of calcined marble, fine sand, gum-tragacanth, the white of eggs, and oil. As some time elapses before the ground hardens, there is no difficulty immediately arising from the act of placing the glass properly, or in removing those which may be found misplaced; but after a certain interval it becomes so extremely solid, that nothing less than violence has any effect upon it. Keysler mentions, that "the paste is first spread in a frame of wood, which must not be less than a foot in breadth and thickness, if the piece be any thing large." The frame is secured by brass nails to a plane of marble or stone; and as some of the most important subjects are twenty feet in length, and fifteen in breadth, an idea may be formed of their very great weight. The fragments of glass are arranged in their proper gradations in cases, which are placed before the artist in the manner that types are set before compositors in printing. The former were so very accurate in imitating the most beautiful strokes of the pencil, that the difference, according to Keysler, seems to consist only in the colours of the copy being more vivid and brilliant than those of the painting. When the copy is completed, they polish them in the same manner usually with mirrors; and after this operation is performed, it is almost impossible to discover that they are composed of an infinite number of fragments, as they rather resemble rich pictures covered with glass. Those pieces that are intended for distant view are never polished.

The pieces of which mosaic work were originally formed were very large, and sometimes gilded and silvered. About the close of the third century, a Florentine, named Andrea Tasai, contemporary with Cimabne, the restorer of the art of painting, introduced an improved manner of executing it, which soon attracted the attention of the rich and powerful, and in consequence mosaic paintings became much more common than they had been for a long time before. Tasai, however, does not deserve the sole merit of reviving the art, as he acquired his skill from Apollonius, a Greek, who had performed several very fine pieces for St. Mark's church at Venice.

A few specimens of the gilded manner of executing figures in mosaic may still be seen in England, and particularly in Westminster Abbey, where the tombs of Edward the Confessor and of Henry III. have been adorned in this way in fanciful figures, some of which are perfect, but the greater part are destroyed by the silly practice of picking out the fragments of glass, to discover what may be seen on each side—the mode of setting them in the cement. "How much," says Keysler, "this curious art has been improved, during the two last centuries, may be easily seen, by comparing the coarse works in some of the old cupolas of the chapels in St. Peter's church with the other pieces lately erected there. The studs in these old works are made of clay burnt, and the surface only tinctured with various colours."

In Clavigero's history of Mexico is described a curious kind of mosaic-work made by the ancient Mexicans of the most delicate and beautiful feathers of birds. They raised for this purpose various species of birds of fine plumage with which that country abounds, not only in the palaces of the king, where there were all sorts of animals, but likewise in private houses; and at certain seasons they carried off their feathers to make use of them on this kind of work, or to sell them at market. They set a high value on the feathers of those wonderful little birds which they call huitzitziln, and the Spaniards picaflores, on account of the smallness, the fineness, and the various colours of them. In these and other beautiful birds, nature supplied them with all the colours which art can produce, and also some which art cannot imitate. At the undertaking of every mosaic work several artists assembled: after having agreed upon a design, and taken their measures and proportions, each artist charged himself with the execution of a certain part of the image, and exerted himself so diligently in it with such patience and application, that he frequently spent a whole day in adjusting a feather; first trying one, then another, viewing it sometimes one way, then another, until he found one which gave his part that ideal perfection proposed to be attained.

When the part which each artist undertook was done, they assembled again to form the entire image from them. If any part was accidentally the least deranged, it was wrought again until it was perfectly finished. They laid hold of the feathers with small pincers, that they might not do them the least injury, and pasted them on the cloth with tzauhtli, or some other glutinous matter; then they united all the parts upon a little table, or a plate of copper, and flattened them softly, until they left the surface of the image so equal and smooth that it appeared to be the work of a pencil.

These were the images so much celebrated by the Spaniards and other European nations. Whoever beheld them was at a loss whether he ought to have praised most the life and beauty of the natural colours, or the dexterity of the artist and the ingenious disposition of art. "These images (says Acosta) are deservedly admired; for it is wonderful how it was possible, with the feathers of birds, to execute works so fine and so equal, that they appear the performance of the pencil; and what neither the pencil nor the colours in painting can effect, they have, when viewed from a side, an appearance so beautiful, so lively, and animated, they give delight to the sight. Some Indians, who are able artists, copy whatever is painted with a pencil so perfectly with plumage, that they rival the best painters of Spain." These works of feathers were even so highly esteemed by the Mexicans as to be valued more than gold.

MOSAMBIQUE, a strait or channel of the Indian Ocean, between the E. coast of Africa and the island of Madagascar, and between 11 and 25° S. lat. It is narrowest in the middle, where it is 240 miles over; and in this part, on the coast of Zanguebar, is a kingdom, island, and town of the same name.

Mosambique, a kingdom of Africa, on the W. side of a channel of the same name, and on the coast of Zanguebar, consisting of three islands. The principal island, called Mosambique, is not more than three miles in length, and half as much in breadth, and is about two miles from the continent. It was seized by the Portuguese in 1497, and they have kept possession of it ever since.

Mosambique, the capital of an island of the same name, on the E. coast of Africa. It is large and well fortified, having a strong citadel to defend the harbour. It belongs to the Portuguese, who have generally a good garrison here, and trade with the natives for gold, elephants teeth, and slaves. They have built several churches and monasteries, and a large hospital for sick sailors. Their ships always call here in going to the East Indies; and the harbour is so commodious that whole fleets may anchor and provide themselves with all necessaries. Lon. 40. 10 E. Lat. 15. 5 S.

MOSBACH, a town of Germany, in the palatinate of the Rhine, with a castle, seated on the Neckar, 26 miles E.N.E. of Heidelberg. Lon. 9. 21 E. Lat. 49. 28 N.

MOSBRUNN, a town of the archduchy of Austria, eight miles S. of Vienna.

MOSBURG, a town of Germany, in the duchy of Carinthia, six miles N.W. of Clagenfurt.

Mosburg, a town of Germany, in Bavaria, seated at the confluence of the Iser and Ambert, nine miles W. of Landschut. Lon. 11. 55 E. Lat. 48. 30 N.

MOSCHATEL (Tuberous), in botany. See Adoca.

MOSCHEL, or Ober Mouschel, a town of Germany, in the duchy of Deux Ponts, 10 miles N.E. of Weissemburg, and 32 N.N.E. of Deux Ponts. Lon. 7. 29 E. Lat. 49. 46 N.

MOSCHION, a name common to four different writers, whose compositions, character, and native place, are unknown. Some fragments of their writings remain, some few verses, and a treatise De mulierum affectibus.

MOSCHUS, a Grecian poet of antiquity, usually coupled with Bion; and they were both of them cotemporaries with Theocritus. In the time of the latter Grecians all the ancient Idylliums were collected and attributed to Theocritus; but the claims of Moschus and Bion have been admitted to some few little pieces; and this is sufficient to make us inquisitive about their characters and story: yet all that can be known about them must be collected from their own remains. Moschus, by composing his delicate elegy on Bion, has given the best memorials of Bion's life. Moschus and Theocritus have by some critics been supposed the same person; but there are irrefragable evidences against it: others will have him as well as Bion to have lived later than Theocritus, upon the authority of Suidas; while others again suppose him to have been the scholar of Bion, and probably his successor in governing the poetic school; which, from the elegy of Moschus, does not seem unlikely. Their remains are to be found in all the editions of the Poetæ Mineros. See Bion.

Moschus. (*moschus*, μοςχος, *mosch*, Arab.). Musk. An unctuous substance, contained in excretory follicles about the navel of the moschus moschiferus, whose strong and permanent smell is peculiar to it, (See Moschus, in zoology.) It is contained in a bag placed near the umbilical region of a ruminating quadruped, resembling the antelope, from which it does not differ sufficiently to form a particular genus. The medicinal and chemical properties of musk and castor are very similar: the virtues of the former are generally believed to be more powerful, and hence musk is preferred in cases of imminent danger. It is prescribed as a powerful antispasmodic in convulsive diseases, hydrophobia, &c. and is by many said to be a violent aphrodisiac.

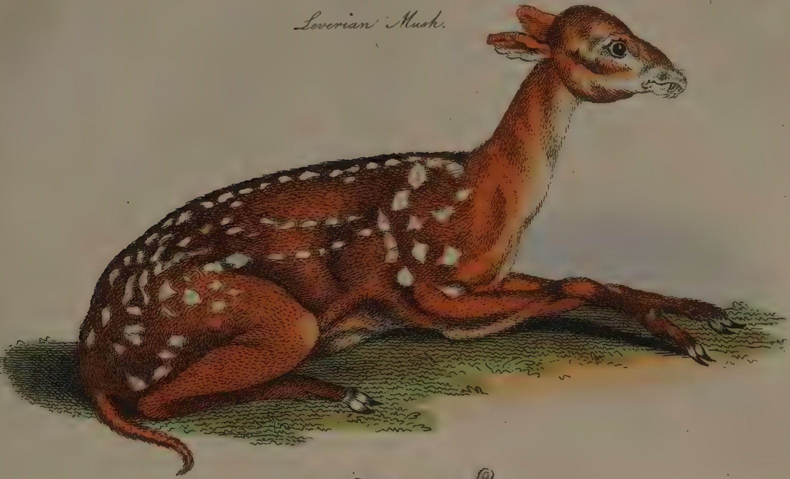
Moschus. Musk. In zoology, a genus of the class mammalia, order pecora. Hornless; fore-teeth, lower eight; tusks, upper solitary, projecting. Six species. The greater number of them afford musk; whence the generic name: a few however have not this property. The substance called musk is extracted from a bag situated near the umbilical region, and chiefly from this organ in the moschus moschifer. The species are as follow:

NATURAL HISTORY.

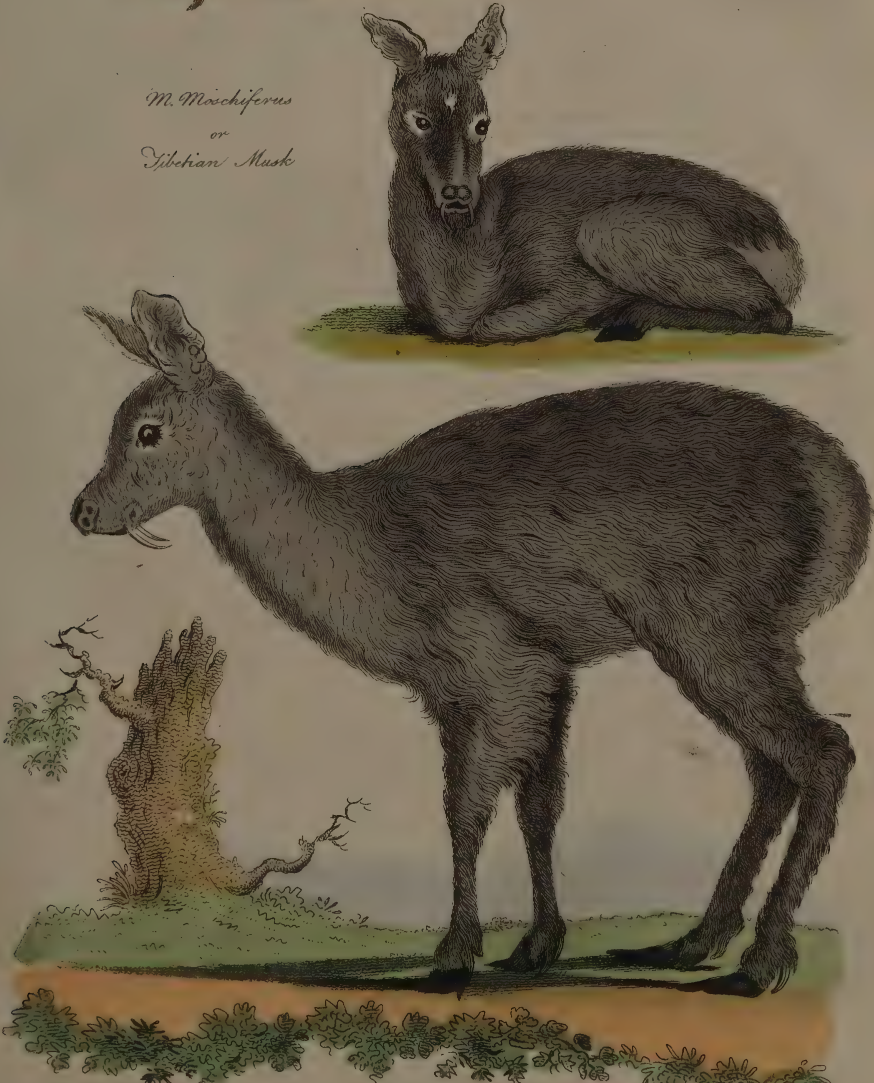
PL. CLXII.

Moschus.

Leverian Musk.



M. Moschiferus
or
Tibetian Musk



London, Published by Sherwood & Co. Paternoster Row, March 1st 1812.

1. M. moschifer. Thibet musk. In form, this animal resembles a small roebuck. It measures three feet three inches in length, and in height between two and three feet. Its upper jaw is considerably longer than the lower. Its tusks are nearly two inches long, and project, naked, beyond the lower jaw. Its ears are long and narrow, within of a pale yellow, and without of a deep brown colour. The hair of the body is very long, and stands erect; each hair is marked from tip to root with short waves; the colour at the roots of the hair is black, in the middle cinereous, and at the tips ferruginous. Each jaw is armed with six grinders. The hoofs are black, long, and divided for a considerable length. The inguinal bag contains musk: this bag, according to Neumann, has no opening like that of the civet cat, and hence the musk is not to be got till after the death of the animal. This chemist informs us he has seen the animal alive, and observed that the apartment in which it was kept had a very strong musky smell; and that on the white walls on which the animal had rubbed itself there was an unctuous matter of the same smell.

This species is a native of Asia, and is found between 44° or 45°, and 60° of north latitude. It inhabits the kingdom of Thibet, the province of Mohang Meng in China, Tonquin and Bontan. In the Russian dominions, and on the confines between Russia and China, it is found in the country around the lake Baikal, and near the rivers Jenesea and Argun.

Naturally a mild and timid animal, the Thibet musk, in the rutting season, in the months of November and December, acquires new courage from the impulse of love. Rival males then combat fiercely with their tusks. As it is naturally timid, so it is also solitary and unsocial. It seeks the cliffs and pine-clad summits of steep and lofty mountains; descending at times into the deep vales by which those are separated. In running, leaping, climbing, swimming, it displays astonishing agility. Few animals that the hunter pursues lead him through greater dangers, or require him to exert such address and activity in the chace. But the value of the musk causes danger to be overlooked; and the animal is shot with arrows, or taken in snares, or sometimes falls by a sudden discharge from a cross-bow placed in its tracks. The flesh, though infected, especially about the rutting time, with the musk, is tolerable food. The skin and hair are not without their uses.

2. M. Indicus. Indian musk. This species is an inhabitant of India; somewhat larger in size than the former; and distinguished by slender legs, oblong, erect ears, and the resemblance which its head bears, in shape, to that of a horse.

3. M. Americanus. Brazilian musk, or wirrebocerra. In size, this animal approaches to an equality with the European roebuck. Its back, sides, chest, and thighs, are of a bright rust colour; but the lower part of the belly and the inside of the thighs white. Its eyes are large and black; its ears four inches long; the tail six inches long; the legs slender, yet muscular.

These creatures, peculiar to Guinea and Brazil, are remarkable for their timidity, and for a correspondent lightness of form, and agility of motion. Like goats, they are sometimes seen standing with their four legs together on the point of a rock. The delicacy of their flesh draws upon them a number of enemies. The Indians, tygers, and other beasts of prey, all eagerly pursue them. Their safety is most endangered when they attempt to swim; for their legs are but very ill adapted to that exercise. They are ranked in this genus, not as affording musk, but as wanting horns.

4. M. meminna. An inhabitant of Java and Ceylon: form is diminutive: not more than one foot five inches in length: its whole weight only five pounds and a half. Its ears large and open; its tail very short; its sides and haunches variegated with spots, and transverse bars of white on a cinereous olive ground. The rest of the upper part of its body is a cinereous olive, without spots. Its throat, breast, and belly are white.

5. M. Javanicus. Java musk. Equal in size to a rabbit, with remarkably slender, puny legs; with its snout and ears bare, without pits in the groin, or under the eye; having tufts on its knees; and under its throat, two long divergent hairs. The neck is hoary, with an intermixture of yellow; a black line marks the crown of the head; the general colour of the body is ferruginous; the neck and belly are white, but the neck variegated with two dusky spots. The tail is of a moderate length, and terminates in a white tuft. A native of Java.

6. M. pygmæus. Guinea musk. This animal, notwithstanding its name, is an inhabitant of the continent of India, and the Oriental islands, rather than of Guinea. It is only nine inches and a half in length; has two small tusks in its upper jaw; large ears; and a tail an inch long. Its belly is white, and the rest of its body tawny; but the specimens vary in colour. Among the Malays, they are caught in great numbers, carried to market in cages, and sold at a very moderate price.

Two sorts of musk are distinguished in commerce; the one is inclosed in the bags, the other is extracted; and each of these is again subdivided according to the country from which they are brought. Hence the difference between the Tonquin or East Indian musk, and the Muscovy or Persian musk. The Tonquin bags have commonly small brownish hairs upon them; the Persian large white ones. The former are accounted the best; but the difference seems to consist rather in quantity than in quality; the thinner and less having bags containing more in proportion to their weight than the others. From the dearness of this drug, it is often adulterated: and there is no determinate criterion to ascertain its purity. The best method is to compare it with real specimens.

Musk to the chemist offers the appearance of a dark brown, or a rusty reddish-coloured substance; occasionally it is clothed like coagulated blood. To the touch it is unctuous, and on drying becomes pulverizable. It has a bitterish savour, and its aroma is peculiarly strong and aromatic; disagreeable, if too concentrated; but when largely diluted with other matters, or greatly extended in the atmosphere, it becomes a pleasant perfume. From its aroma being remarkably diffusive and tenacious, every thing in its vicinity becomes perfectly infected with it, and retains it a long time. Water will extract two-fifths of it; and the distilled water is highly impregnated with its aroma and savour: alkohol takes up one third of it, but retains little or nothing of its aroma. Nitrous and vitriolic acids totally dissolve it; the first destroys the whole of its aroma, the latter the greater part of it. Mineral alkali extracts from it the smell of volatile alkali, when these two substances are rubbed together. Oils have no action upon it. Cast on red-hot coals, it emits an urinous smell. On distillation Neumann obtained the same products as from other animal substances: viz. an empyreumatic oil, a volatile spirit, and salt. By impregnating the waters and spirits distilled from odoriferous vegetables with a minute portion of musk, their fragrance is considerably improved, without receiving any of its own peculiar aroma. According to Fourcroy, it resembles castor in its chemical properties; and consists of resin united to a certain quantity of mucilage, bitter extract, and salt: its virtues are stronger than those of castor.

MOSCOVY. See Russia.

MOSCOW, formerly a duchy, but now one of the 41 governments of Russia; bounded on the N. by the government of Tver, on the E. by that of Great Volodimir, on the S. by the governments of Kalugo and Resan, and on the W. by those of Tver and Smolensko.

Moscow, or Moskva, a city of Russia, and capital of a government, on a river of the same name. It derives its name from the river Moskva, which runs on the south side of it. Moscow was founded in the year 1156; at least it appears to have been a city in 1175. It lies in a round situation, formed by the winding of the river.

Moscow is represented as the largest town in Europe; its circumference within the rampart, which encloses the suburbs, being exactly 39 versts or 26 miles; but it is built in so straggling and disjointed a manner, that its population in no degree corresponds to its extent. Some Russian authors state its inhabitants at 500,000 souls, a number evidently exaggerated. According to a late computation, which Mr. Coxe says may be depended upon, Moscow contains within the ramparts 250,000 souls, and in the adjacent villages 50,000. The streets of Moscow are in general exceedingly long and broad: some of them are paved; others, particularly those in the suburbs, are formed with trunks of trees, or are boarded with planks like the floor of a room; wretched hovels are blended with large palaces; cottages of one story stand next to the most superb and stately mansions. Many brick structures are covered with wooden tops; some of the wooden houses are painted: others have iron doors and roofs. Numerous churches present themselves in every quarter, built in a peculiar style of architecture; some with domes of copper, others of tin, gilt or painted green, and many roofed with wood. In a word, some parts of this vast city have the look of a sequestered desert, other quarters of a populous town; some of a contemptible village, others of a great capital.

Moscow may be considered as a town built upon the Asiatic model, but gradually becoming more and more European, and exhibiting in its present state a motley mixture of discordant architecture. It is distributed into the following divisions. 1. The Kremlin. This stands in the central and highest part of the city; is of a triangular form, and about two miles in circumference; and is surrounded by high walls of stone and brick, which were constructed in the year 1491, under the reign of Ivan Vassilievitch I. It contains the ancient palace of the czars, several churches, two convents, the patriarchal palace, the arsenal now in ruins, and one private house, which belonged to Boris Godunof before he was raised to the throne. 2. Khitaigorod, or the Chinese town, is inclosed on one side by that wall of the Kremlin which runs from the Moskva to the Neglina; and on the other side by a brick wall of inferior height. It is much larger than the Kremlin, and contains the university, the printing-house, and many other public buildings, and all the tradesmens shops. The edifices are mostly stuccoed or white-washed, and it has the only street in Moscow in which the houses stand close to one another without any intervals between them. 3. The Bielgorod, or White Town, which runs quite round the two preceding divisions, is supposed to derive its name from a white wall with which it was formerly inclosed, and of which some remains are still to be seen. 4. Semlainogorod, which environs all the three other quarters, takes its denomination from a circular rampart of earth with which it is encompassed. These two last mentioned divisions exhibit a grotesque group of churches, convents, palaces, brick and wooden houses, and mean hovels, in no degree superior to peasants cottages. 5. The Sloboda, or suburbs, form a vast exterior circle round all the parts already described, and are invested with a low rampart and ditch. These suburbs contain, beside buildings of all kinds and denominations, corn-fields, much open pasture, and some small lakes, which give rise to the Neglina. The river Moskva, from which the city takes its name, flows through it in a winding channel; but, excepting in spring, is only navigable for rafts. It receives the Yausa in the Semlainogorod, and the Neglina at the western extremity of the Kremlin: the beds of both these last-mentioned rivulets are in summer little better than dry channels.

The places of divine worship at Moscow are exceedingly numerous: including chapels, they amount to above 1000: there are 484 public churches, of which 199 are of brick, and the others of wood; the former are commonly stuccoed or white-washed, the latter painted of a red colour. The most ancient churches of Moscow are generally square buildings, with a cupola and four small domes, some whereof are of copper or iron gilt; others of tin, either plain or painted green. These cupolas and domes are for the most part ornamented with crosses entwined with thin chains or wires. The church of the Holy Trinity, sometimes called the church of Jerusalem, which stands in the Khitaigorod, close to the gate leading into the Kremlin, has a kind of high steeple and nine or ten domes; it was built in the reign of Ivon Vassilievitch II. The inside of the churches is mostly composed of three parts: that called by the Greeks ϖρογαος, by the Russians trapeza, the body, and the sanctuary or shrine. Over the door of each church is the portrait of the saint to whom it is dedicated, to which the common people pay their homage as they pass along by taking off their hats, crossing themselves, and occasionally touching the ground with their heads. The bells, which form no inconsiderable part of public worship in this country, as the length or shortness of their peals ascertains the greater or lesser sanctity of the day, are hung in belfreys detached from the church: they do not swing like our bells; but are fixed immoveably to the beams, and are rung by a rope tied to the clapper and pulled sideways. Some of these bells are of a stupendous size; one in the tower of St. Ivan's church weighs 3551 Russian poods, or 127,836 English pounds. It has always been esteemed a meritorious act of religion to present a church with bells; and the piety of the donor has been measured by their magnitude. According to this mode of estimation, Boris Godonof, who gave a bell of 288,000 pounds to the cathedral of Moscow, was the most pious sovereign of Russia, until he was surpassed by the empress Anne, at whose expence a bell was cast weighing 432,000 pounds, and which exceeded in bigness every bell in the known world. The height of this enormous bell is 19 feet, its circumference at the bottom 21 yards 11 inches; its greatest thickness 23 inches. The beam to which this vast machine was fastened being accidentally burnt, the bell fell down, and a fragment was broken off towards the bottom, which left an aperture large enough to admit two persons a-breast without stooping.

Moscow is the centre of the inland commerce of Russia, and particularly connects the trade between Europe and Siberia. The only navigation to this city is formed by the Moskva, which falling into the Occa near Columna, communicates by means of that river with the Volga. But as the Moskva is only navigable in spring upon the melting of the snows, the principal merchandise is conveyed to and from Moscow upon sledges in winter. As to the retail commerce here, the whole of it is carried on in the Khitaigorod; where, according to a custom common in Russia, as well as in most kingdoms of the East, all the shops are collected together in one spot. The place is like a kind of fair, consisting of many rows of low brick buildings; the interval between them resembling alleys. These shops or booths occupy a considerable space; they do not, as with us, make part of the houses inhabited by the tradesmen, but are quite detached from their dwellings, which for the most part are at some distance in another quarter of the town. The tradesman comes to his shop in the morning, remains there all day, and returns home to his family in the afternoon. Every trade has its separate department; and they who sell the same goods have booths adjoining to each other. Furs and skins form the most considerable article of commerce in Moscow; and the shops which vend those commodities occupy several streets.

Among the curiosities of Moscow, the market for the sale of houses is not the least remarkable. It is held in a large open space in one of the suburbs; and exhibits a great variety of ready-made houses, thickly strewed upon the ground. The purchaser who wants a dwelling repairs to this spot, mentions the number of rooms he requires, examines the different timbers, which are regularly numbered, and bargains for that which suits him. The house is sometimes paid for on the spot, and taken away by the purchaser; or sometimes the vender contracts to transport and erect it upon the place where it is designed to stand. It may appear incredible to assert that a dwelling may be thus bought, removed, raised, and inhabited, within the space of a week; but we shall conceive it practicable by considering that these ready-made houses are in general merely collections of trunks of trees tenanted and mortoised at each extremity into one another, so that no thing more is required than the labour of transporting and adjusting them. But this summary mode of building is not always peculiar to the meaner hovels; as wooden structures of very large dimensions and handsome appearance are occasionally formed in Russia with an expedition almost inconceivable to the inhabitants of other countries. A remarkable instance of this dispatch was displayed the last time the empress came to Moscow. Her majesty proposed to reside in the mansion of prince Galitzin, which is esteemed the completest edifice in this city; but as it was not sufficiently spacious for her reception, a temporary addition of wood, larger than the original house, and containing a magnificent suite of apartments, was begun and finished within the space of six weeks. This meteor-like fabric was so handsome and commodious, that the materials, which were taken down at her majesty's departure, were to be reconstructed as a kind of imperial villa upon an eminence near the city. Mr. Coxe mentions an admirable police in this city for preventing riots, or for stopping the concourse of people in case of fires, which are very frequent and violent in those parts, where the houses are mostly of wood, and the streets are laid with timber. At the entrance of each street there is a chevaux de frize gate, one end whereof turns upon a pivot, and the other rolls upon a wheel; near it is a centry-box in which a man is occasionally stationed. In times of riot or fire the centinel shuts the gate, and all passage is immediately stopped. Lon. 37. 31 E. Lat. 55. 45 N.

Dr. E. D. Clarke, a recent traveller in Russia, gives the following picturesque and lively representation of the first appearance of Moscow to a stranger:

"We arrived at the season of the year in which this city is most interesting to strangers. Moscow is in every thing extraordinary; as well in disappointing expectation as in surpassing it; in causing wonder and derision, pleasure and regret. Let me conduct the reader back with me again to the gate by which we entered, and thence through the streets. Numerous spires, glittering with gold, amidst burnished domes, and painted palaces, appear in the midst of an open plain, for several versts before you reach this gate. Having passed, you look about, and wonder what is become of the city, or where you are; and are ready to ask, once more, How far is it to Moscow? They will tell you, "This is Moscow!" and you behold nothing but a wide and scattered suburb, huts, gardens, pigsties, brick walls, churches, dunghills, palaces, timber-yards, warehouses, and a refuse as it were of materials sufficient to stock an empire with miserable towns and miserable villages. One might imagine all the states of Europe and Asia had sent a building, by way of representative, to Moscow: and under this impression the eye is presented with deputies from all countries, holding congress: timber huts from regions beyond the Arctic; plastered palaces from Sweden and Denmark, not white-washed since their arrival; painted walls from the Tyrol; mosques from Constantinople; Tartar temples from Bucharia; pagodas, pavilions and virandas from China; cabarets from Spain; dungeons, prisons, and public offices from France; architectural ruins from Rome; terraces and trellisses from Naples; and warehouses from Wapping.

"Having heard accounts of its immense population, you wander through deserted streets. Passing suddenly towards the quarter where the shops are situated, you might walk upon the heads of thousands. The daily throng is there so immense, that unable to force a passage through it, or assign any motive that might convene such a multitude; you ask the cause, and are told that it is always the same. Nor is the costume less various than the aspect of the buildings; Greeks, Turks, Tartars, Cossacks, Chinese, Muscovites, English, French, Italians, Poles, Germans, all parade in the habits of their respective countries."

MOSELLE, a river of Germany, which rises in the mountains of Vauge in Lorrain, and, running through that duchy and the electorate of Triers, falls into the Rhine at Coblentz.

MOSES, the son of Amram and Jochebed, was born in the year 1571 before Christ. Pharaoh king of Egypt, perceiving that the Hebrews were become a formidable nation, issued forth an edict commanding all the male children to be put to death. Jochebed the mother of Moses, having, to avoid this cruel edict, concealed her son for three months, at length made an ark or basket of bulrushes, daubed it with pitch, laid the child in it, and exposed him on the banks of the Nile.—Thermuthis the king's daughter, who happened to be walking by the river's side, perceived the floating cradle, commanded it to be brought to her, and struck with the beauty of the child, determined to preserve his life. In three years afterwards the princess adopted him for her own son, called his name Moses, and caused him to be diligently instructed in all the learning of the Egyptians. But his father and mother, to whom he was restored by a fortunate accident, were at still greater pains to teach him the history and religion of his fathers. Many things are related by historians concerning the first period of Moses's life, which are not to be found in the Old Testament. Thus, we are merely told (Acts vii. 20.) that "Moses was *exceeding* fair," or as the original (ασειος τῳ Θεῳ) should be rendered *beautiful through God;* i. e. through God's peculiar favour and blessing. But Josephus relates, that when Moses was but three years old, no one who saw him could help being struck with his beauty, and that as he was carried about, people would leave their business to gaze at him; and he introduces Pharaoh's daughter calling him *a child divine in form.* Philo (in Vitâ Mosis) says, that at his birth he had a more elegant and beautiful appearance than denoted an ordinary person. And it appears from Justin (lib. xxxvi. cap. 2.) that the fame of Moses's uncommon beauty had spread among the heathen.

According to Josephus and Eusebius, he made war on the Ethiopians, and completely defeated them. They add, that the city Saba, in which the enemy had been forced to take refuge, was betrayed into his hands by the king's daughter, who became deeply enamoured of him, when she beheld from the top of the walls his valorous exploits at the head of the Egyptian army. But as the truth of this expedition is more than doubtful, we shall therefore confine ourselves to the narrative of sacred writ, which commences at the fortieth year of Moses's life. He then left the court of Pharaoh, and went to visit his countrymen the Hebrews, who groaned under the ill-usage and oppression of their unfeeling masters. Having perceived an Egyptian smiting an Hebrew, he slew the Egyptian, and buried him in the sand. But he was obliged, in consequence of this murder, to fly into the land of Midian, where he married Zipporah, daughter of the priest Jethro, by whom he had two sons, Gershom and Eliezar. Here he lived 40 years; during which time his employment was to tend the flocks of his father-in-law. Having one day led his flock towards Mount Horeb, God appeared to him in the midst of a bush which burned with fire but was not consumed, and commanded him to go and deliver his brethren from their bondage. Moses at first refused to go; but was at length prevailed on by two miracles which the Almighty wrought for his conviction. Upon his return to Egypt, he, together with his brother Aaron, went to the court of Pharaoh, and told him that God commanded him to let the Hebrews go to offer sacrifices in the desert of Arabia. But the impious monarch disregarded this command, and caused the labour of the Israelites to be doubled. The messengers of the Almighty again returned to the king, and wrought a miracle in his sight, that they might move his heart, and induce him to let the people depart. Aaron having cast down his miraculous rod, it was immediately converted into a serpent; but the same thing being performed by the magicians, the king's heart was hardened more and more; and his obstinacy at last drew down the judgments of the Almighty on his kingdom, which was afflicted with ten dreadful plagues. The first was the changing the waters of the Nile and of all the rivers into blood, so that the Egyptians died of thirst. In consequence of the second plague, the land was covered with innumerable swarms of frogs, which entered even into Pharaoh's palace. By the third plague, the dust was converted into lice, which cruelly tormented both man and beast. The fourth plague was a multitude of destructive flies which spread throughout Egypt, and infested the whole country. The fifth was a sudden pestilence, which destroyed all the cattle of the Egyptians, without injuring those of the Israelites. The sixth produced numberless ulcers and fiery biles upon man and upon beast. The seventh was a dreadful storm of hail, accompanied with thunder and lightning, which destroyed every thing that was in the field, whether man or beast, and spared only the land of Goshen, where the children of Israel dwelt. By the eighth plague swarms of locusts were brought into the country, which devoured every green herb, the fruit of the trees, and the produce of the harvest. By the ninth plague thick darkness covered all the land of Egypt, except the dwellings of the children of Israel. The tenth and last plague was the death of the first-born in Egypt, who were all in one night cut off by the destroying angel, from the first-born of the king to the first-born of the slaves and of the cattle. This dreadful calamity moved the heart of the hardened Pharaoh, and he at length consented to allow the people of Israel to depart from his kingdom.

Profane authors who have spoken of Moses seem to have been in part acquainted with these mighty wonders. That he performed miracles must have been allowed by many, by whom he was considered as a famous magician; and he could scarcely appear in any other light to men who did not acknowledge him for the messenger of the Almighty. Both Diodorus and Herodotus mention the distressed state to which Egypt was reduced by these terrible calamities. The Hebrews, amounting to the number of 600,000 men, without reckoning women and children, left Egypt on the 15th day of the month Nisan, which, in memory of this deliverance, was thenceforth reckoned the first month of their year. Scarcely had they reached the shore of the Red Sea when Pharaoh with a powerful army set out in pursuit of them. On this occasion Moses stretched forth his rod upon the sea; and the waters thereof being divided, remained suspended on both sides till the Hebrews passed through dry-footed. The Egyptians determined to follow the same course; but God caused a violent wind to blow, which brought back the waters to their bed, and the whole army of Pharaoh perished in the waves.

After the miraculous passage of the Red Sea, the army proceeded towards Mount Sinai, and arrived at Marah, where the waters were bitter; but Moses, by casting a tree into them, rendered them fit for drinking. Their tenth encampment was at Rephidim; where Moses drew water from the rock in Horeb, by smiting it with his rod. Here likewise Amalek attacked Israel. While Joshua fought against the Amalekites, Moses stood on the top of a hill, and lifted up his hands; in consequence of which the Israelites prevailed, and cut their enemies in pieces. They at length arrived at the foot of Mount Sinai on the third day of the ninth month after their departure from Egypt. Moses having ascended several times into the Mount, received the law from the hand of God himself in the midst of thunders and lightnings, and concluded the famous covenant betwixt the Lord and the children of Israel. When he descended from Sinai, he found that the people had fallen into the idolatrous worship of the golden calf. The messenger of God, shocked at such ingratitude, broke in pieces the tables of the law which he carried in his hands, and put 23,000 of the transgressors to the sword. He afterwards reascended into the mountain, and there obtained new tables of stone on which the law was inscribed. When Moses descended, his face shone so that the Israelites dared not to come nigh unto him, and he was obliged to cover it with a veil. The Israelites were here employed in constructing the tabernacle according to a pattern shown them by God. It was erected and consecrated at the foot of the Mount Sinai on the first day of the first month of the second year after their departure from Egypt; and it served the Israelites instead of a temple till the time of Solomon, who built a house for the God of his fathers after a model shown him by David.

Moses having dedicated the tabernacle, he consecrated Aaron and his sons to be its ministers, and appointed the Levites to its service. He likewise gave various commandments concerning the worship of God and the political government of the Jews. This was a theocracy in the full extent of the word. God himself governed them immediately by means of his servant Moses, whom he had chosen to be the interpreter of his will to the people; and he required all the honours belonging to their king to be paid unto himself. He dwelt in his tabernacle, which was situated in the middle of the camp, like a monarch in his palace. He gave answers to those who consulted him, and himself denounced punishments against the transgressors of his laws. This properly was the time of the theocracy, taken in its full extent; for God was not only considered as the divinity who was the object of their religious worship, but as the sovereign to whom the honours of supreme majesty were paid. The case was nearly the same under Joshua; who, being filled with the spirit of Moses, undertook nothing without consulting God. Every measure, both of the leader and of the people, was regulated by the direction of the Almighty, who rewarded their fidelity and obedience by a series of miracles, victories, and successes. After Moses had regulated every thing regarding the civil administration, and the marching of the troops, he led the Israelites to the confines of Canaan, to the foot of Mount Nebo. Here the Lord commanded him to ascend into the mountain; whence he showed him the promised land, whereinto he was not permitted to enter. He immediately after yielded up the ghost, without sickness or pain, in the 120th year of his age, and 1451 years before Jesus Christ.

Moses is incontestably the author of the first five books of the Old Testament, which go by the name of the Pentateuch; and which are acknowledged to be inspired, by the Jews and by Christians. Some, however, have denied that Moses was the author of these books; and have founded their opinion on this, that he always speaks of himself in the third person. But this manner of writing is by no means peculiar to Moses: it occurs also in several ancient historians; such as Xenophon, Cæsar, Josephus, &c. who, possessed of more modesty or good sense than some modern historians, whose egotism is altogether disgusting, have not like them left to posterity a spectacle of ridiculous vanity and self-conceit. After all, it is proper to observe, that profane authors have related many falsehoods and absurdities concerning Moses, and concerning the origin and religion of the Jews, with which they were but little acquainted. Plutarch, in his book concerning Isis and Osiris, says, that Judæus and Hierosolymus were brothers, and descended from Typhon; and that the former gave his name to the country and its inhabitants, and the latter to the capital city. Others say that they came from Mount Ida in Phrygia. Strabo is the only author who speaks any thing like reason and truth concerning them; though he too says that they were descended from the Egyptians, and considers Moses their legislator as an Egyptian priest. He acknowledges, however, that they were a people strictly just and sincerely religious. Other authors by whom they are mentioned seem not to have had the smallest acquaintance either with their laws or their worship. They frequently confound them with the Christians, as is the case with Juvenal, Tacitus, and Quintilian.

MOSHEIM (John Lawrence), a learned German divine, was born in 1695, and acquired so much fame by his talents as to be invited to several universities. He settled at Gottingen, of which he was chosen chancellor, and died there in 1755. He translated Cudworth's Intellectual System into Latin; but his greatest work is his Ecclesiastical History, which has been translated into English by Dr. Maclaine.

MOSQUE, a temple or place of religious worship among the Mahometans.

All mosques are square buildings, generally built with stone; before the chief gate there is a square court, paved with white marble, and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there are a great number of lamps; and between these hang many crystal rings, ostriches' eggs, and other curiosities, which, when the lamps are lighted, make a fine shew. As it is not lawful to enter the mosques with shoes or stockings on, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosques, but stay in the porches without. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another: these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayer by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers, of what religion soever, are entertained during three days. Each mosque has also a place called tarbé, which is the burying-place of its founders; within which is a tomb six or seven feet long, covered with green velvet or satin, at the ends of which are two tapers, and round it several seats for those who read the koran, and pray for the souls of the deceased.

MOSQUITO SHORE, a country of New Spain, on the Atlantic Ocean. It extends eastward from Point Castile, the boundary dividing it from the bay of Honduras, to Cape Gracios-a-Dios, 87 leagues; and southward, from Cape Gracios-a-Dios to St. John's river, 94 leagues. The interior part of the country is bounded by the lake Nicaragua, and fenced by mountains stretching to the west. In magnitude it exceeds Portugal; is well watered by navigable rivers and lakes; abounds in fish, game, and provisions of all sorts; furnishes every necessary for raising cattle and stock, on plantations of every kind and to any extent; and is clothed with woods producing timber for every purpose at land or sea. The soil is superior to that of the West India islands; the air and climate are more salubrious; and the destructive ravages of hurricanes and earthquakes have never been known here. The Mosquito Indians are so situated between morasses and inaccessible mountains, and a coast full of rocks and shoals, that no attempts against them by the Spaniards, whom they mortally hate, could ever succeed. Nevertheless they are a mild and inoffensive people, of great probity, and will never trust a man who has once deceived them. They had so great veneration for the English, that they spontaneously put themselves under the protection of the crown of Great Britain. This was first done when the duke of Albemarle was governor of Jamaica; and the king of the Mosquitos received a commission from his grace, under the seal of that island; after which time, they were not only steady in their alliance with the English, but warm in their affection, and very useful to them on many occasions. But the connexion between the English and the Mosquitos no longer subsists. By a convention with Spain, in 1786, the English, in consideration of certain cessions on the coast of Honduras, agreed to evacuate this country totally; and it is now a province of Spain. See HONDURAS.

MOSS on trees, in gardening. The growth of large quantities of moss on any kind of tree is a distemper of very bad consequence to its increase, and much damages the fruit of the trees of our orchards. The present remedy is the scraping it off from the body and large branches by means of a kind of wooden knife that will not hurt the bark, or with a piece of rough hair cloth, which does very well after a soaking rain. But the most effectual cure is the taking away the cause. This is to be done by draining off all the superfluous moisture from about the roots of the trees, and may greatly be guarded against in the first planting of the trees, by not setting them too deep.

If trees stand too thick in a cold ground, they will always be covered with moss; and the best way to remedy the fault is to thin them. When the young branches of trees are covered with a long and shaggy moss, it will utterly ruin them; and there is no way to prevent it but to cut off the branches near the trunk, and even to take off the head of the tree if necessary; for it will sprout again: and if the cause be in the mean time removed by thinning the plantation, or draining the land and stirring the ground well, the young shoots will continue clear after this.

If the trees are covered with moss in consequence of the ground's being too dry, as this will happen from either extreme in the soil, then the proper remedy is the laying mud from the bottom of a pond or river pretty thick about the root, opening the ground to some distance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moss, but it will also prevent the other great mischief which fruit-trees are liable to in dry grounds, which is the falling off of the fruit too early.

The mosses which cover the trunks of trees, as they always are freshest and most vigorous on the side which points to the north, if only produced on that, serve to preserve the trunk of the tree from the severity of the north-winds, and direct the traveller in his way, by always plainly pointing out that part of the compass.

Moss is also a name given by some to the boggy ground in many parts of England, otherwise called a fen and bog.

Moss (Robert), an English divine, was born at Gillingham, in Norfolk, in 1666, and educated at Norwich school, from whence he removed to Bennet college, Cambridge, of which he was chosen fellow in 1685. In 1698 he became preacher to the society of Gray's-inn. He was created D. D. when queen Anne visited Cambridge in 1707, at which time he was one of her chaplains. In 1712 he was preferred to the deanery of Ely. He died in 1729. Dr. Moss was the author of eight volumes of sermons, and some tracts.

Moss, a town of Norway, in the province of Aggerhuys, on the E. side of Christiania Bay, 15 miles N. of Frederickstadt, and 28 S. of Christiania. Lon. 10. 48 E. Lat. 58. 38 N.

To Moss. *v. a.* (from the noun.) To cover with moss (*Shakspeare*).

MOSSES, in botany. See Musci.

MO'SSINESS. *s.* (from *mossy.*) The state of being covered or overgrown with moss (*Bacon*).

MO'SSY. *a.* (from *moss.*) Overgrown with moss; covered with moss (*Pope*).

MOST. *a.* the superlative of *more.* (mæꞅꞇ, Saxon.) Consisting of the greatest number; consisting of the greatest quantity (*Arbuthnot*).

Most. *ad.* 1. In the greatest degree (*Locke*). 2. The particle noting the superlative degree: as, *the* most *wise:*

Most. *s.* 1. The greatest number (*Addison*). 2. The greatest value (*L'Estrange.*) 3. The greatest degree; the greatest quantity; the utmost (*Bacon*).

MO'STIC. *s.* A painter's staff (*Ains.*).

MO'STLY. *ad.* (from *most.*) For the greatest part (*Bacon*).

MOSTRA, in the Italian music, a mark at the end of a line or space, to show that the first note of the next line is in that place: and if this note be accompanied with a sharp or flat, it is proper to place these characters along with the mostra.

MOTACILLA. Warbler. In zoology, a genus of the class aves, order passeres. Bill subulate, straight; the mandibles nearly equal, nostrils oboval; tongue lacerate at the end.

This is a very extensive genus of birds; comprising not fewer than a hundred and ninety-three species, scattered over the globe; a very great number of which are natives of Europe, and many of them of our own country. We shall first give a catalogue of those most worthy of notice, dividing them as nearly as we can into tribes, and shall then subjoin such particulars concerning a few of them as may be most instructive or entertaining.

1. M. phœnicurus. Red-start. Common to our own country. Three varieties.

2. M. luscina. Nightingale. Common to Europe, Asia, and Africa. Three varieties; one with the body entirely white; one of more than ordinary size.

3. M. modularis. Hedge-warbler. Hedge-sparrow. Common to Europe.

4. M. silvatica. Wood-wren. Inhabits our own country.

5. M. hortensis. Petty-chaps. Inhabits France and Italy.

6. M. sylvia. White-throat. Inhabits England, and Europe generally. Two varieties, from variety of colours.

7. M. nævia. Fig-eater. Inhabits Italy: feeds on figs and grapes; whence its specific name.

8. M. alba. White-wagtail. Inhabits England, and Europe generally. Three varieties, from variety of colour. The tribe wagtail includes twenty or more than twenty distinct species of this genus, distinguished into pied, cinereous, green, &c. wag-tails; or else into Indian, African, &c. from their native habitations.

9. M. oenanthe. Wheat-ear. Inhabits England, and Europe in general, as also Asia and Africa. The wheat-ear tribe embraces ten or eleven varieties of the genus.

10. M. rubetra. Whin-chat. Inhabits Europe. The tribe of whin-chats comprise three or four varieties of the genus.

11. M. rubicola. Stone-chat. Moor-titling. Inhabits England, Siberia, and is found in Europe in general.

12. M. atricapilla. Black-cap. Inhabits England, and Europe generally. Four varieties, from variations in its colours.

13. M. magna. Dark-warbler. The tribe of warblers peculiarly so called are common to tropical and other warm climates, and comprise not less than a hundred varieties of the present genus. Not one of them is found native in our own country.

14. M. atrata. Black-red-tail. The red-tail tribe comprises four species, of which one inhabits Europe, the others South America.

15. M. rubecola. Robin-red-breast. Inhabits England, and Europe generally. Three varieties: the common, grey, with throat and breast ferruginous: a second, entirely white; the third with chin white, wing-coverts and feathers variegated.

16. M. Troglodytes. Wren. Inhabits England, and Europe at large; found also in Asia. The tribe comprises six species of the genus.

Of this selection we have only space to describe more particularly the following:

I. M. phœnicurus. Red-start. Though this bird has been described among the nightingale tribe by some naturalists, and in France is known by the same name, rossignolle de muraille, yet it is considerably inferior both in extent and variety of voice; and it differs still more widely in its colour, form, and manners. It is also inferior in point of size, being even smaller than the red-breast; while its shape is longer and more slender. But what most remarkably distinguishes this bird is a large black patch upon the fore part of the neck, which reaches up as far as the eyes and bill. The top of the head, the hind part of the neck, and the back, are of a deep but shining grey. The wings are of a dusky black, and the breast, under the patch of black already noticed, shines with a fine igneous red, growing more and more faint towards the flanks and belly, which are of a white colour.

This species makes its appearance in spring, along with the other summer birds. It commonly alights upon old towers and uninhabited houses, choosing always the highest and most inaccessible pinnacles. It is found, too, in the most impenetrable recesses of dark woods, where it indulges, undisturbed, its solitary habits, and utters its plaintive notes.

The red-start nestles in the holes of those old walls which it frequents, or in the hollow of a rotten tree, and, sometimes, in the cliff of a rock. The young ones are excluded in the month of May: they are five or six in number. While the female is employed in hatching and rearing them, the male is commonly stationed, as a centinel, upon a point of the rock, or upon the top of the wall, whence he utters his uninterrupted song; a pledge to the mother, that no danger is approaching her family. It is only when taken young that the red-start will acquire any familiarity with man; for, though this bird be frequently a near neighbour of the human race, he still preserves his native wildness and timidity. He acquires neither the confidence and intimacy that distinguish the red-breast, the gaiety of the lark, nor the vivacity of the nightingale. His disposition is melancholy, and his manners wild. If taken when old, he refuses all food, preferring death to captivity; or, if he survive his freedom, his obstinate silence and sullen grief plainly indicate how deeply he is penetrated with the misery of his condition.

II. M. lucina. Nightingale. This bird, the most celebrated of all the feathered race, for its song, visits England as early as the month of April, and takes its departure in August; but is never found to migrate so far north as Scotland, or west as Cornwall and Wales. Though the climate of Sweden be more severe, it annually visits that kingdom, by the accounts of Linnéus. So various, sweet, and continued are the notes of this bird, that the songs of the other warblers, taken in their utmost extent, appear despicable when compared with those of the nightingale. His variety seems inexhaustible; for he never repeats the same notes a second time, at least servilely; and if the same bar be heard twice, it is always upon a different key, and with new embellishments. This great Chorypheus of the spring, as often as he prepares to conduct the hymn of Nature, begins by feeble, timid, and indecisive tones, as if to try his instrument. By degrees, he assumes more confidence, becomes gradually more warm and animated, till, at last, like the ancient musicians, he captivates and overwhelms his audience, by the full exertion of his astonishing powers. These qualities of the nightingale were not unknown to the ancients; and Pliny has given an admirable description of them in his tenth book, where he mentions the spirit of emulation which it displays in song; and observes that two of them will continue to carry on an obstinate contest for victory, till the vanquished bird drops breathless to the ground. *Victa morte finit sæpe vitam, spiritu prius deficiente quam cantu.*

In England, the nightingales frequent thick hedges, and low coppices, and generally keep in the middle of the bush; so that they are very rarely seen. They begin their song in the evening, and continue it the whole night. Perhaps somewhat of their fame is owing to this circumstance: during the solemn stillness of night, when all the animals are at rest, every sound is heard with advantage, and has, amidst darkness, a more powerful effect upon the imagination. These vigils did not escape the notice of the Mantuan poet, who thus describes them:

> Qualis populea mœrens philomela sub umbrâ,
> Amissos queritur fœtus, quos durus arator
> Observans nido implumes detraxit: at illa
> Flet noctem, ramoque sedens, miserabile carmen
> Integrat, et mœstis latè loca questibus implet.
> GEORG. iv. l. 511.

> As Philomel in poplar shades, alone,
> For her lost offspring pours a mother's moan;
> Which some rough plowman marking for his prey,
> From the warm nest, unfledged, hath dragg'd away;
> Perch'd on a bough, she all night long complains,
> And fills the grove with sad repeated strains.
> WARTON.

Though the nightingale be a very small bird, his voice is heard farther than the human; being distinguished, in a calm night, at the distance of almost a mile all around the bush where he sits. When tamed, he sings for nine months in the year; a circumstance, from which we may conclude, that it is with no intention to sooth the toils of the female during incubation. In fact, the female hatches because she is prompted to that function by a passion, perhaps stronger than that of love; and seems to feel in it an inward joy, which renders her independent of all consolation. The warbling of the male is, in like manner, the result neither of duty nor of prudential considerations: it is the natural and unavoidable expression of the sexual passion; a passion which gratification no sooner extinguishes, than the gift of song is lost, and the pretended solace of the female is at an end. From the end of June, the nightingale ceases to sing: his voice becomes then more like the croaking of a toad than that of the tuneful philomel we have described.

The nightingale's talents for speaking are reported to be equal, if not superior, to his musical ones. Gesner gravely mentions two kept at Ratisbon by the landlord of an inn, that spent whole nights in adjusting the political interests of Europe. Germannicus and Drusus, the two sons of Claudius, are said, by Pliny, to have educated one so liberally, that he delivered orations both in Greek and Latin. Hist. Nat. x. 42.

This bird's fame for music is often fatal to its liberty. In order to secure its song, it is frequently made a prisoner; and the greatest part of what is written upon the subject, is with a view to instruct its tyrants how to perpetuate its slavery.— The nightingale is about six inches from the tip of the bill to that of the tail. Its colours are very plain, the head and back being of a pale tawny colour, dashed with olive; the throat, breast, and upper part of the belly, of a light ash-colour; the lower part of the belly almost white. The wings and tail are of a tawny red.

III. M. rubecola. Robin-red-breast. The little birds, of this name, on account of their near approaches to our dwellings, and their familiarity with man, are, perhaps, the best known of all the feathered race, except such as are kept in domestication. They are capable of enduring the most severe winters in this island; but, at the approach of such inclement seasons, they leave the woods, where they reside in summer, and are willing to acknowledge a kind of dependence upon man. It is then that they enter the orchards of the farmer, and establish themselves in some hedge, or unoccupied house; making frequent calls at the kitchen-door, during the continuance of frost, in order to pick up any crumbs and fragments that have been dropped there, before they are destroyed or congealed by the frost. Many of them have been fed from the window during the whole season: some intrust themselves even within the room; and it is seldom that they repent of this confidence; for they are universal favourites, and, almost always, meet with that generous treatment which their wants or their trust in the human race so well merit.

It is remarkable, that a bird which remains in North Britain all the year round should migrate from France, during the winter months. Such, however, is the case: in France the red-breast frequents the hedges and dwelling-houses, for a short time, in autumn and spring; but regularly, in the dead of winter, when the hard frost commences, disappears. In his spring visit, he makes but a short stay, hasting, as he then is, to enter the forest, that he may there, amidst the spreading leaves, enjoy solitude and love.

The red-breast builds its nest at the foot of some thick shrub, or upon a tuft of grass, able to support it. The materials of which it is composed are oak-leaves, moss, and a bed of feathers within. Sometimes, after the edifice is finished, the bird covers it entirely over with leaves, allowing only a small passage to remain, sufficient to admit its body.

During the season of nestling and incubation, the male makes the grove resound with his soft and melodious lays. His warbling is soothing and tender, animated occasionally with notes of a louder tone, and sometimes, too, graced with those touching and engaging accents, that seem to express the ardour of his love. In the sweet society of his female, he seems to be wholly absorbed: at the interference of other company, he becomes fretful and enraged; for no stranger is permitted to intermeddle with his joy: even those of his own species he pursues with rage, till he banishes them from the district he has chosen for himself. His love exhibits a strange mixture of jealousy and attachment.

The food of the red-breast varies with the season. In spring, he feeds upon insects and worms, which he pursues with address and nimbleness, in those moist and shady districts where he then resides. In autumn, he devours all kinds of seeds and fruits that are produced in the district, not excepting the apple and the grape.

There is no bird more active, none satisfied with a smaller portion of rest, than this bird: he is the first that appears in the woods at the break of day, and the last that retires thither in the evening to enjoy repose. This species is spread over the whole of Europe, from Norway and Sweden, to the coast of the Mediterranean.

IV. M. Troglodytes. Wren. The ancients gave this small bird the name of Troglodyte, from a fancied resemblance between its manners and those of a race of men who were said to inhabit dens and caves of the earth. There is some difference among naturalists, in classing and distinguishing the tribe of wrens; a circumstance that might be expected in subjects so minute, and so slightly discriminated by nature. The common wren is known from its residence. It frequents farm-houses, and country villages, where it is seen hopping about, full of life and vivacity, even in the midst of winter, expressing, towards evening, its happiness, in cheerful and well-toned notes. It appears upon the top of heaps of fire-wood, or by the sides of old walls, whence it disappears in a moment, by making its way into some small hole. It remains not, however, long concealed; but returns to make quick and inconstant movements with its little tail, always raised in an almost perpendicular direction.

The flights of the wren are very short, and expeditious. When flying, it moves its wings with such rapidity, that they become invisible. Its length is about three inches and a half, and its breadth, when the wings are extended, five. The whole plumage is transversely barred with undulating lines of brown and black; on the belly and lower parts it inclines to grey.

This bird, slender as it is in form, is almost the only one that remains with us during the most severe winter; and it is the only one of the whole feathered creation which continues its warbling in a season, in which the universal silence of the woods and groves is interrupted only by the croaking of ravens. During a fall of snow it is still better heard; for then it enters the court-yards, the door of the stable or dairy, seeking, among the garbage, for the dead bodies of insects, or their larves.

V. M. sutoria. Tailor-bird. Tailor-wren. This is a very small yellow bird, about three inches long, and weighs only three-sixteenths of an ounce. It inhabits India, and constructs a very curious nest by sewing the edges of one or more leaves together, so as to form a conical repository for its eggs and young, which it lines afterwards with feathers and vegetable down: this singular work is performed by using the bill instead of a needle, and by employing vegetable fibres for thread. The eggs are white, and are said to be not larger than what are usually called ants-eggs.

VI. M. oenanthe, or wheat-ear, is distinguished by its hoary back; its front, line above the eyes, rump and base of the tail white; through the eyes a black band. The distribution of these colours vary however so as to produce four or five varieties. The bird is met with as far north as Greenland, and as far east as India. It visits England annually in the beginning of March, and leaves us in September. It chiefly frequents heaths, warrens, and the edges of hills; feeds on insects, particularly earth-worms; grows prodigiously fat, and breeds in rabbits burrows, or under a stone. The eggs are from five to eight in number, of a light-blue, with a deep blue circle at the large end: the young are hatched in the middle of May. In some parts of England these birds are very plentiful. About East Bourne, in Sussex, they are taken in snares made of horse-hair, placed beneath a long turf; being very timid, the motion of a cloud, or the appearance of a hawk, will drive them for shelter into these traps. The numbers annually ensnared in the neighbourhood of East Bourne are said to amount to eighteen hundred and forty dozen; and they are usually sold at sixpence a dozen: the smaller are eaten in the country, the larger are selected for the London market, and when potted by the poulterers are by many as much esteemed as the ortolan on the continent.

VII. M. cyanea. Superb warbler. This bird is one of the most beautiful of the whole genus. It is five and a half inches long, black-blue, beneath white; feathers of the head long; lax turgid; front, cheeks, and lunula on the neck fine blue. There is another variety, from a different disposition of the colours. The female is brown above, beneath white; blue round the eyes. It is an inhabitant of New Holland, the second variety, of Manilla.

We cannot conclude this short history of the genus motacilla or warblers without observing that there are some circumstances attending the singing of birds which seem highly flattering to man; circumstances that may lead him to imagine, that their musical endowments are conferred upon them chiefly to promote his pleasure. While the canopy of the sky, the expanse of the ocean, and the verdure of the fields, are fitted to give delight to one of his senses, the harmony of the feathered tribe seems equally calculated to sooth and captivate another; and it may therefore, with the same propriety, be adduced as a proof of the goodness and munificence of the Great Parent of the human race.

In support of this pleasing illusion, if such it be, let us observe, that, in general, the musical birds reside in the vicinity of man, and are rarely found in the uninhabited parts of the earth. While a solemn silence reigns in the depth of the forest, and in the barren wild, every cottage, as you approach the cultivated plains, is honoured with the visits, and charmed with the melody of the singing birds. Often has the bewildered traveller, in the dreary tracts of South America, conceived his first hopes of safety from hearing the notes of the musical birds, and been conducted, by a band of songsters, to the habitation of his fellow-creatures. On the other hand, the silent birds, and such as have harsh and disagreeable voices, generally inhabit the inaccessible wilds, the gloomy forest, or the distant parts of the ocean. There their screaming notes overcome the noise of the winds and water, and prevent them from being dispersed from each other amidst the fury of these tempestuous elements.

Further, it is not often, that those birds which are capable of imitating sounds are possessed of what may be called a taste for music.—They have no predilection for melodious notes; but will imitate the harshest screams as readily as the finest air. They seem, in a great degree, insensible to the effect of their own powers, and the charms which they possess; for it does not appear that the birds of one species are delighted with the warblings of those of a different. Man, however, derives pleasure from them all; a pleasure which never rises higher than when it is produced by the combined effect of every note in the grove.

MOTA'TION. *s.* Act of moving.

MOTE. *s.* (moꞇ, Saxon.) A small particle of matter; any thing proverbially little (*Bacon*).

MOTE, for *might*, or *must* (*Spenser*).

MOTE, MOTA. (Fr. *mot*, a word.) Discussion, debate. It is a word which frequently occurs, in our ancient customs, for a meeting, court, or plea. The term is still retained in law under the form of MOOT.

Of motes, by the Saxons also called gemotes, considered in the sense of assemblies, or courts, there were divers kinds; as wittenagemote, folkegemote, schiregemote, hundredgemote, burgemote, wardegemote, haligemote, swainegemote, &c. See each under its proper article, WITTENAGEMOTE, FOLKEGEMOTE, &c.

MOTE, *mota*, was also used for a fortress, or castle; as, mota de Windsor, &c.

MOTE also denoted a standing water to keep fish in; and sometimes a large ditch encompassing a castle, or dwelling-house.

MOTETTO, in the Italian music, a kind of church-music, composed with much art and ingenuity from one to eight parts, with or without instruments, usually accompanied with a thorough bass. When the composer gives a loose to his fancy, without confining himself to any rules, subjects or passions, it is called fantasia or ricercata. The word is sometimes used for pieces made to hymns to saints, &c. and whole psalms are often thus called; and was probably derived from *motus*, motion, because the church songs were designed to move the hearts of the hearers; or because this kind of composition was originally of a very gay and lively nature.

MOTH, in entomology. See PHALÆNA.

MO'THER. *s.* (moðoꞃ, Saxon.) 1. A woman that has borne a child; correlative to son or daughter (*Shakspeare*). 2. That which has produced any thing (*Arb.*). 3. That which has preceded in time: as, a mother *church to chapels*. 4. That which requires reverence and obedience (*Ayliffe*). 5. Hysterical passion (*Graunt*). 6. A familiar term of address to an old woman. 7. (*moeder*, Dutch.) A thick substance concreting in liquors; the lees or scum concreted (*Dryden*).

MO'THER. *a.* Had at the birth; native: as, *mother* wit (*Shakspeare*).

To MO'THER. *v. n.* To gather concretion (*Dryden*).

MO'THER-IN-LAW. *s.* The mother of a husband or wife (*Matthew*).

MOTHER OF PEARL. The beautiful white and irridescent enamel that lines the interior of the shell of the mytilus margaritiferus, or mother of pearl mussel, (see MYTILUS): the shell being thus denominated from its generating this elegant lining. This shell grows to a very considerable size, is of a flattened and rounded shape, with the back or hinge-part straight. From this cartilaginous hinge, when in a petrified state, is very rare and beauful extraneous fossil called the astrodamas (helmintholithus astrodamas of Linneus); which when cut and polished, in the disposition of its fibres, and in its colours, bears some resemblance to the eye of a peacock's feather.

Mother of pearl is also sometimes obtained from the shells of some species of the mya, and of the oyster, but by far the best specimens are obtained from the mother of pearl mussel-shell. It is occasionally found, however, in the haliotis iris, and turbo olearius, but the membranaceous parts of these shells are more compact and dense than those of the mytilus margaritiferus.

These shells, when deprived of their hardening substance, or carbonat of lime, by an acid menstruum, appear to be formed of various membranes applied *stratum super stratum.* Each membrane has a corresponding coat, or crust of carbonat of lime, which is so situate that it is always between every two membranes, beginning with the epidermis, and ending with the last formed internal membrane. The animals which inhabit these stratified shells increase their habitation by the addition of a stratum of carbonat of lime, secured by a new membrane; and as every additional stratum exceeds in extent that which was previously formed, the shell becomes stronger in proportion as it is enlarged, and the growth and age of the animal is denoted by the number of the stratum which concur in forming the shell.

For the chemical properties of mother of pearl, see the article CONCHOLOGY.

MOTHER OF THYME. See THYMUS.

MO'THERHOOD. *s.* (from *mother.*) The office or character of a mother (*Donne*).

MO'THERLESS. *a.* (from *mother.*) Destitute of a mother (*Waller*).

MO'THERLY. *a.* (*mother* and *like.*) Belonging to a mother; suitable to a mother (*Ral.*).

MO'THERLY. *ad.* (from *mother.*) In manner of a mother (*Donne*).

MO'THERY. *a.* (from *mother.*) Concreted; full of concretions; dreggy; feculent.

MOTHMU'LLEIN. *s.* (*blatteria*, Latin.) A plant (*Miller*).

MO'THY. *a.* (from *moth.*) Full of moths.

MO'TION. *s.* (*motio*, Latin.) 1. The act of changing place (*Milton*). 2. Manner of moving the body; port; gait (*Waller*). 3. Change of posture; action (*Dryden*). 4. Agitation; intestine action (*Gay*). 5. Direction;

tendency (*Milton*). 6. Impulse communicated (*Dryden*). 7. Tendency of the mind (*South*). 8. Proposal made (*Shakspeare.*)

To Mo'tion. *v. a.* (from the noun.) To propose.

Motion, primarily so called, or local motion, has been defined a continued and successive change of place; or that state of a body, whereby it corresponds successively to several different places, or is present successively in different parts of space.

In this sense, the doctrine and laws of motion make the subject of mechanics, or dynamics.

The ancient philosophers considered motion in a more general and extensive manner; they defined it a passage out of one state into another; and thus made six kinds of motion, viz. creation, generation, corruption, augmentation, diminution, and lation, or local motion.

Some of the later schoolmen reduce these six kinds of motion to four: the first is general, including any passage from one state to another; under which kind come creation, production, and mutation. The second is a passage of something already existing from one state to another; and thus generation is a motion. The third is a successive passage of something already existing from one term to another; and thus alteration, and accretion, are species of motion. The last is lation, or local motion; and thus walking is motion.

But the latest philosophers deny any other species besides local motion; and reduce all the sorts above-mentioned to this one. So that we have here only to do with lation, or local motion; whereof the rest are only so many different determinations, or effects.

Physical writers, both ancient and modern, have ever been perplexed about the nature and definition of local motion. The Peripatetics define it by, *Actus entis in potentia, prout in potentia,* Arist. 3. Phys. cap. 2. but this notion seems too abstract and metaphysical for our days, and is of no use in explaining the properties of motion.

The Epicureans explain motion by the migration of a body, or a part of a body from one place to another; on which definition the later Epicureans refine, and call it, the migration or passage of a body from space to space; thus substituting the word space for that of place.

The Cartesians define motion, a passage or removal of one part of matter out of the neighbourhood of those parts immediately contiguous thereto, into the neighbourhood of others.

Which definition agrees, in effect, with that of the Epicureans: all the difference between them consisting in this; that what the one call body, and place, the other call matter, and contiguous parts.

Borelli, and other late writers after him, define motion more accurately and fully, the successive passage of a body from one place to another, in a determinate time, by becoming successively contiguous to all the parts of the intermediate space.

Motion, then, is agreed to be the translation of a body from place to place; but authors differ much when they come to explain wherein this translation consists. And hence their divisions of motion become exceedingly precarious. Aristotle, and the Peripatetics, divide all motion into natural and violent.

Motion (Natural), is that which has its principle, or moving force, within the moving body. Such is that of a stone falling towards the centre of the earth.

Motion (Violent), is that whose principle is without, and against which the moving body makes a resistance. Such is that of a stone thrown upwards.

The moderns generally divide motion into absolute and relative.

Motion (Absolute), is the change of absolute place, in any moving body; whose celerity, therefore, will be measured by the quantity of absolute space which the moveable body runs through.

Motion (Relative), is a mutation of the relative or vulgar place of the moving body; and has its celerity estimated by the quantity of relative space run through.

A late acute writer, Mr. Young, defines motion, change of place; and as he endeavours to obviate the principal objections to this definition, we shall quote part of his defence. "It is said (he observes) by some, that change implies motion, and therefore cannot be a part of its definition, being the very thing defined. To this I answer, We are speaking of the sensible idea of motion, as it appears to our sight; now changes do appear to our view, and to all our senses, which give us no idea of motion. Changes in heat or cold; in colour, flavour, smell, sound, hardness, softness, pain, pleasure; in these, and many other ideas, changes do not produce ideas like that produced by a ball rolling or a stone falling. We may, perhaps, ultimately trace them to motion, but to insensible motions: to motions which arise only in reflection, and constitute no part of the actual idea of change. We can, therefore, conceive of change, without conceiving at the same time of motion. Change is a generic idea, including many species; motion, as a sensible idea, is a species of that genus. Change is therefore a necessary part of the definition of motion; it marks the genus of the thing defined. Motion is a change; but as there are many species of change, which of those species is motion? The answer, It is a change of place. This marks the species; and distinguishes it from change of colour, of temperament, and figure."

This is the ablest defence of an attempt to define motion that we have ever seen; and at first view the definition itself appears to be perfect. Aristotle, the prince of definers, "considers a definition as a speech declaring what a thing is. Every thing essential to the thing defined, and nothing more, must be contained in the definition. Now the essence of a thing consists of these two parts; first, what is common to it with other things of the same kind; and secondly, what distinguishes it from other things of the same kind. The first is called the genus of the thing; the second, its specific difference. The definition, therefore, consists of those two parts."

In obedience to this rule, the definition under consideration seems to consist of the genus, signified by the word change; and of the specific difference, denoted by the words of place. But does the speech change of place really declare what motion is? We cannot admit that it does; as, in our apprehension, a change of place is the effect of motion, and not motion itself. Suppose a lover of dialectics undertaking to define the stroke by which he saw his neighbour wounded with a bludgeon; what should we think of his art were he to call it a contusion on the head? He might say that contusion is a general term, as contusions may be produced on the arms, on the legs, and on various parts of the body; and as there are many species of contusion, if he were asked which of those species was the stroke to be defined, he might answer, "a contusion on the head." Here would be apparently the genus and specific difference; the former denoted by contusion, and the latter by the words on the head. But would this be a definition of a stroke? No, surely: a contusion on the head may be the effect of a stroke; but it can no more be the stroke itself, than a blow can be a bludgeon, or a flesh wound the point of a sword. Equally evident it is, that a change of place cannot be motion; because every body must have been actually moved before we can discern, or even conceive, a change of its place.

The act of changing place would perhaps come nearer to a definition of motion; but so far would it be from "a speech declaring what motion is," that we are confident a man who had never by any of his senses perceived a body in actual motion, would acquire no ideas whatever from the words, "act of changing place." He might have experienced changes in heat, cold, smell, and sound; but he could not possibly combine the ideas of changes with the signification of the word place, were he even capable of understanding that word, which to us appears to be more than doubtful.

The distinctions of motion into different kinds have been no less various, and no less insignificant, than the several definitions of it. The moderns who reject the peripatetic division of motion into four classes, yet consider it themselves as either absolute or relative. Thus we are told, as above, that "absolute motion is the change of absolute place, and that its celerity must be measured by the quantity of absolute space which the moving body runs through in a given time." "Relative motion, on the other hand, is a mutation of the relative or vulgar place of the moving body, and has its celerity estimated by the quantity of relative space run through."

Now it is obvious, that this distinction conveys no ideas without a farther explanation of the terms by which it is expressed; but that explananation is impossible to be given. Thus, before we can understand what absolute motion is, we must understand what is meant by absolute place. But absolute place is a contradiction; for all place is relative, and consists in the positions of different bodies with regard to one another. Were a globe in the regions of empty space to be put in motion by Almighty Power, and all the rest of the corporeal world to be soon afterwards annihilated, the motion would undoubtedly continue unchanged; and yet according to this distinction, it would be at first relative, and afterwards absolute. That the beginning of such a motion would be perceptible, and the remainder of it imperceptible, is readily granted; but on this account to consider it as of two kinds, is as absurd as to suppose the motion of the minute-hand of a clock to be affected by our looking at it. But we dare not dwell longer upon these distinctions.

Motion (Laws of). See Axioms and Dynamics.

Motion (Quantity of), whether always the same? The Cartesians maintained that the Creator at the beginning impressed a certain quantity of motion on bodies; and that under such laws, as that no part of it should be lost, but the same portion of motion should be constantly preserved in matter: and hence they conclude, that if any moving body strike on any other body, the former loses no more of its motion than it communicates to the latter. This principle sir Isaac Newton overturns in the following words: "From the various compositions of two motions, it is manifest there is not always the same quantity of motion in the world; for if two balls, joined together by a slender wire, revolve with an uniform motion about their common centre of gravity, and at the same time that centre be carried uniformly in a right line drawn in the plane of their circular motion, the sum of the motions of the two balls as often as they are in a right line, drawn from their common centre of gravity, will be greater than the sum of their motions when they are in a line perpendicular to that other. Whence it appears, that motion may be both generated and lost. But by reason of the tenacity of fluid bodies, and the friction of their parts, with the weakness of the elastic power in solid bodies, nature seems to incline much rather to the destruction than the production of motion; and in reality, motion becomes continually less and less. For bodies which are either so perfectly hard, or so soft, as to have no elastic power, will not rebound from each other: their impenetrability will only stop their motion. And if two such bodies, equal to each other, be carried with equal, but opposite motions, so as to meet in a void space, by the the laws of motion they must stop in the very place of concourse, lose all their motion, and be at rest for ever; unless they have an elastic power to give them a new motion. If they have elasticity enough to enable them to rebound with $\frac{1}{4}$, or $\frac{1}{2}$, or $\frac{3}{4}$, of the force wherewith they meet, they will lose $\frac{3}{4}$, or $\frac{1}{2}$, or $\frac{1}{4}$, of their motion. And this is confirmed by experiments: for if two equal pendulums be let fall from equal heights, so as to strike full on each other; if those pendulums be of lead, or soft clay, they will lose all, or almost all, their motion; and if they be of any elastic matter, they will only retain so much motion as they receive from their elastic power." If it be asked, how it happens, that motion being thus continually lost, should be continually renewed again; the same author adds, that it is renewed from some active principles, "Such as the cause of gravity, whereby the planet sand comets preserve their motions in their orbits, and all bodies acquire a great degree of motion in falling; and the cause of fermentation, whereby the heart and blood of animals preserve a perpetual warmth and motion; the inner parts of the earth are kept continually warmed; many bodies burn and shine; and the sun himself burns and shines, and with his light warms and cheers all things;" (as also from the cause of elasticity, by which bodies restore themselves into their former figures) "for we find but little motion in the world, except what plainly flows either from these active principles, or from the command of the willer." The preservation of the same quantity of motion in the universe, was a principle laid down universally by Descartes; but has been found false, and holds true only in the same direction, which is thus expressed by sir Isaac Newton: "The quantity of motion, which is collected by taking the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves." Newt. Princip. lib. i. See ante.

Some philosophers, after Descartes, have supposed the preservation of the same force or *vis viva*. See the articles Force and Vis viva.

But this holds only in elastic bodies, when there is a shock; and hence those philosophers have been led to maintain, that all bodies were elastic, at least in their elements, and that an inflexible body was impossible, being repugnant to the law of continuity. See Dynamics.

Motion (Equable), is that by which the moving body proceeds with exactly the same velocity or celerity; passing always over equal spaces in equal times.

The laws of uniform Motion are these: 1. The spaces described, or passed over, are in the compound ratio of the velocities, and the times of describing those spaces. So that, if V and v be any two uniform velocities, S and s the spaces described or passed over by them, in the respective times T and t:

$$\text{then is } S : s :: TV : tv,$$
$$\text{or } 20 : 12 :: 4 \times 5 : 3 \times 4;$$
$$\text{taking } T=4,\ t=3,\ V=5, \text{ and } v=4.$$

2. In uniform motions, the time is as the space directly, and as the velocity reciprocally; or as the space divided by the velocity. So that

$$T : t :: \frac{S}{V} : \frac{s}{v} \text{ or } :: Sv : sV.$$

3. The velocity is as the space directly, and the time reciprocally; or as the space divided by the time.

$$\text{That is, } V : v :: \frac{S}{T} : \frac{s}{t} \text{ or } :: St : sT.$$

Motion (Accelerated), is that which continually receives fresh accessions of velocity. And it is said to be uniformly accelerated, when its accessions of velocity are equal in equal times; such as that which is produced by the continual action of one and the same force, like the force of gravity, &c.

Motion (Retarded), is that whose velocity continually decreases. And it is said to be uniformly retarded, when its decrease is continually proportional to the time, or by equal quantities in equal times; like that which is produced by the continual opposition of one and the same force; such is the force of gravity in uniformly retarding the motion of a body that is thrown upwards.

The laws of motion, uniformly accelerated or retarded, are these:

1. In uniformly varied motions, the space, S or s, is as the square of the time, or as the square of the greatest velocity, or as the rectangle or product of the time and velocity.

$$\text{That is, } S : s :: T^2 : t^2 :: V^2 : v^2 :: TV : tv.$$

2. The velocity is as the time, or as the space divided by the time, or as the square root of the space.

$$\text{That is, } V : v :: T : t :: \frac{S}{T} : \frac{s}{t} :: \surd S : \surd s.$$

3. The time is as the velocity, or as the space divided by the velocity, or as the square root of the space.

$$\text{That is, } T : t :: V : v :: \frac{S}{V} : \frac{s}{v} :: \surd S : \surd s.$$

4. When a space is described, or passed over, by an uniformly varied motion, the velocity either beginning at nothing, and continually accelerated; or else beginning at some determinate velocity, and continually retarded till the velocity be reduced to nothing; then the space, so run over by the variable motion, will be exactly equal to half the space that would be run over in the same time by the greatest velocity if uniformly continued for that time. See Acceleration.

Motion (Perpetual), is a motion which is supplied and renewed from itself, without the intervention of any external cause.

The celebrated problem of a perpetual motion consists in the inventing a machine, which has the principle of its motion within itself; and is a problem that has employed the mathematicians for 2000 years; though none perhaps have prosecuted it with attention and earnestness equal to those of the present age. Infinite are the schemes, designs, plans, engines, wheels, &c. to which this long-desired perpetual motion has given birth.

But M. De la Hire has proved the impossibility of any such machine, and finds that it amounts to this; viz. to find a body which is both heavier and lighter at the same time; or to find a body which is heavier than itself. Indeed there seems but little in nature to countenance all this assiduity and expectation: among all the laws of matter and motion, we know of none yet that seem likely to furnish any principle or foundation for such an effect.

Action and re-action it is allowed are always equal; and a body that gives any quantity of motion to another, always loses just so much of its own; but under the present state of things, the resistance of the air, the friction of the parts of machines, &c. do necessarily retard every motion.

To continue the motion therefore either, first, there must be a supply from some foreign cause; which in a perpetual motion is excluded.

Or, 2dly, all resistance from the friction of the parts of matter must be removed; which necessarily implies a change in the nature of things.

Or, 3dly and lastly, there must be some method of gaining a force equivalent to what is lost, by the artful disposition and combination of mechanic powers; to which last point then all endeavours are to be directed: but how, or by what means, such force should be gained, is still a mystery.

The multiplication of powers or forces, it is certain, avails nothing; for what is gained in power is lost in time, so that the quantity of motion still remains the same. This is an inviolable law of nature; by which nothing is left to art, but the choice of the several combinations that may produce the same effect.

Motion, in astronomy, is peculiarly applied to the orderly courses of the heavenly bodies.

The motions of the celestial luminaries are of two kinds: diurnal, or common; and secondary, or proper.

Motion (Diurnal, or primary), is that with which all the heavenly bodies, and the whole mundane sphere, appear to revolve every day round the earth, from east to west. This is also called the motion of the primum mobile, and the common motion, to distinguish it from that rotation which is peculiar to each planet, &c.

Motion (Secondary, or proper), is that with which a star, planet, or the like, advances a certain space every day from the west towards the east. See the several motions of each luminary, with the irregularities, &c. of them under the proper articles, Earth, Moon, Star, &c.

Motion (Angular), is that by which the angular position of any thing varies. See Angular.

Motion (Horary), is the motion during each hour. See Horary.

Motion (Paracentric) of Impetus. See Paracentric.

Motion of Trepidation, &c. See Trepidation and Libration.

Motion (Muscular.) See Muscles.

Motion (Peristaltic.) See Peristaltic.

Motion, in the manage. A horse is said to have a good motion when he moves and bends his fore-legs with great ease and freedom upon the manage. But if a horse trot right out, and keeps his body straight and his head high, and bends his fore-legs handsomely, then to say he has a good motion implies the liberty of the action of the fore-hand. See the articles ACTION, PROGRESSION, &c.

MO'TIONLESS. *a.* (from *motion.*) Wanting motion; being without motion (*Black.*).

MO'TIVE. *a.* (*motivus*, Lat.) 1. Causing motion; having motion (*Hooker*). 2. Having the power to move; having power to change place (*Wilkins*).

MOTIVE POWER or FORCE, is the whole power or force acting upon any body, or quantity of matter, to move it; and is proportional to the momentum or quantity of motion it can produce in a given time. To distinguish it from the accelerative force, which is considered as affecting the celerity only.

MO'TIVE. *s.* (*motif*, French.) 1. That which determines the choice; that which incites the action (*Locke*). 2. Mover: not in use (*Shakspeare*).

MO'TLEY. *a.* Mingled of various colours.

MO'TOR. *s.* (*moteur*, Fr.) A mover (*Br.*).

MOTMOT, in ornithology. See MOMATUS.

MOTO. (Ital.) In music, a word applied adverbially to the manner or style of performing any composition; and signifying that it is to be sung or played with emphasis and agitation.

MOTO CONTRARIO. (Ital.) An expression applied to that progression of the different harmonic parts of a composition by which they move in opposite directions.

MOTORII OCULORUM. (*nervi motori*, so called from their office.) The third pair of nerves of the brain. They arise from the crura cerebri, and are distributed on the muscles of the bulb of the eye.

MO'TORY. *a.* (*motorius*, Latin.) Giving motion (*Ray*).

MOTOUALIS, a small nation of Syria, inhabiting to the east of the country of the Drusas, in the valley which separates their mountains from those of Damascus.

MOTTE (Anthony Houdart de la), an ingenious Frenchman, greatly distinguished by his writings in prose and verse, and by his literary contests with many eminent persons, was born at Paris in 1672. He wrote with very different success, no man having been more praised or more criticised than he was: his literary paradoxes, his singular systems in all branches of polite learning, and above all his judgment upon the ancients, which, like those of Perrault, were thought disrespectful and detracting, raised him up formidable adversaries. Racine, Boileau, Rousseau, and madam Dacier, were among the number of those who made it their business to avenge antiquity on a man who, with more wit than genius or learning, assumed a kind of dictatorial authority in the province of belles lettres. He became blind in the latter years of his life, and died in 1731. He wrote a great deal in epic poetry, tragedy, comedy, lyric, pastoral, and fables; besides a vast variety of discourses, critical and academical, in prose. A complete edition of all his works was published in 11 vols. 8vo, in 1754; though, as has been said of our Swift, his reputation had been better consulted by reducing them to three or four.

MO'TTO. *s.* (*motto*, Italian.) A sentence or word added to a device, or prefixed to any thing written (*Addison*).

To MOVE. *v. a.* (*moveo*, Latin.) 1. To put out of one place into another; to put in motion (*Job*). 2. To give an impulse to (*Decay of Piety*). 3. To propose; to recommend (*Davies*). 4. To persuade; to prevail on (*South*). 5. To affect; to touch pathetically; to stir passion (*Dryden*). 6. To make angry (*Shakspeare*). 7. To put into commotion (*Ruth*). 8. To incite (*Milton*). 9. To conduct regularly in motion (*Milton*).

To MOVE. *v. n.* 1. To be in a state of changing place (*Milton*). 2. To go from one place to another (*Shakspeare*). 3. To walk; to bear the body (*Dryden*). 4. To go forward (*Dryden*). 5. To change the posture of the body in ceremony (*Esther*).

MO'VEABLE. *a.* (from *move.*) 1. Capable of being moved; not fixed; portable (*Addis.*). 2. Changing the time of the year (*Holder*).

MOVEABLE FEASTS, are such as are not always held on the same day of the year or month; though they may be on the same day of the week. Thus, Easter is a moveable feast; being always held on the Sunday which falls upon or next after the first full moon following the 21st of March. See Philos. Trans. Numb. 240, p. 185. All the other moveable feasts follow Easter, keeping their constant distance from it; so that they are fixed with respect to it, though moveable through the course of the year. Such are Septuagesima, Sexagesima, Ash-Wednesday, Ascension-day, Pentecost, Trinity-Sunday, &c.

MO'VEABLES. *s.* (*meubles*, Fr.) Goods; furniture: distinguished from real or immoveable possessions, as lands or houses (*Shak.*).

MO'VEABLENESS. *s.* (from *moveable.*) Mobility; possibility to be moved.

MO'VEABLY. *ad.* (from *moveable.*) So as it may be moved (*Grew*).

MO'VELESS. *a.* Unmoved; not to be put out of the place (*Boyle*).

MO'VEMENT. *s.* (*mouvement*, French.) 1. Manner of moving (*Pope*). 2. Motion (*Pope*).

MOVEMENT, a term often used in the same sense with automaton. The most usual movements for keeping time, are clocks and watches: the latter are such as shew the parts of time by inspection, and are portable in the pocket; the former such as publish it by sounds, and are fixed as furniture.

MOVEMENT, in music, the name given to any single strain, or to any part of a composition comprehended under the same measure, or time. When an overture, concerto, song, or any other piece, changes its time and measure, either from one species to another, as from common-time to triple, or *vice versa*; or in the same species, as from triple-time, adagio, to triple-time, allegro, or the contrary; it is then said to change its movement: so that every composition consists of as many movements as there are positive changes in the time or measure.

Movement, in military affairs, an evolution.

MO'VENT. *a.* (*movens*, Lat.) Moving (*Grew*).

Mo'vent. *s.* (*movens*, Latin.) That which moves another (*Glanville*).

MO'VER. *s.* (from *move.*) 1. The person or thing that gives motion (*Shakspeare*). 2. Something that moves, or stands not still (*Dryden*). 3. A proposer (*Bacon*).

MO'VING. *part. a.* Pathetic; touching; adapted to affect the passions (*Blackmore*).

Moving plants. See Hedysarum, Tremella, and Mimosa.

MO'VINGLY. *ad.* Pathetically; in such a manner as to seize the passions (*Addison*).

MOULD. *s.* (*moegel*, Swedish.) 1. A kind of concretion on the top or outside of things kept motionless and damp (*Bacon*). 2. (molꝺ, Saxon.) Earth; soil; ground in which any thing grows (*Sandys*). 3. Matter of which any thing is made (*Addison*). 4. (*molde*, Spanish.) The matrix in which any thing is cast, or receives its form (*Black.*). 5. Cast; form (*Prior*). 6. The suture or contexture of the skull (*Ainsworth*).

Mould, or Mold, in the mechanic arts, &c. a cavity cut with a design to give its form or impression to some softer matter applied therein, of great use in sculpture, foundery, &c. The workmen employed in melting the mineral or metallic glebe dug out of mines, have each their several moulds to receive the melted metal as it comes out of the furnace; but these are different according to the diversity of metals and works. In gold-mines they have moulds for ingots; in silver-mines, for bars; in copper and lead mines, for pigs or salmons; in tin-mines, for pigs and ingots; and in iron-mines, for saws, chimney-backs, anvils, cauldrons, pots, and other large utensils and merchandizes of iron, which are here cast as it were at first hand.

Moulds, in the manufacture of paper, are little frames composed of several brass or iron wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened; these moulds are more usually called frames, or forms.

Moulds for leaden bullets, are little iron-pincers, each of whose branches terminates in an hemispherical concavity, which, when shut, form an intire sphere; in the lips or sides where the branches meet, is a little jet or hole through which the melted lead is conveyed.

Moulds (Glazier's). The glaziers have two kinds of moulds, both serving to cast their lead. In the one they cast the lead into long rods or canes fit to be drawn through the vice, and the grooves formed therein; this they sometimes call ingot-mould. In the other they mould those little pieces of lead a line thick, and two lines broad, fastened to the iron-bars; these may be also cast in the vice.

Moulds, among plumbers, are the tables whereon they cast the sheets of lead. These they sometimes call simple tables; besides which they have other real moulds wherewith they cast pipes without soldering.

Moulds, used in basket-making, are very simple, consisting ordinarily of a willow, or osier, turned or bent into an oval, circle, square, or other figure, according to the baskets, panniers, hampers, hats, and other utensils intended. On these moulds they make or more properly measure all their work, and accordingly they have them of all sizes, shapes, &c.

Moulds, among tallow-chandlers, are of two kinds; the first for the common dipped candles, being the vessel wherein the melted tallow is disposed, and the wick dipped; this is of wood, of a triangular form, and supported on one of its angles, so that it has an opening of near a foot at top: the other, used in the fabric of mould candles, is of brass, pewter, or tin; here each candle has its several moulds. See Candle.

Mould, among gold-beaters, a certain number of leaves of vellum, or pieces of guts, cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver, which they beat on the marble with the hammer. They have four kinds of moulds, two whereof are vellum, and two of gut; the smallest of those of vellum consists of forty or fifty leaves, the largest contains an hundred; for the others, each contains five hundred leaves. The moulds have all their several cases, consisting of two pieces of parchment, serving to keep the leaves of the mould in their place, and prevent their being disordered in beating.

Mould, in ship-building, a thin flexible piece of timber, used by shipwrights as a pattern whereby to form the different curves of the timbers, and other compassing pieces in a ship's frame. There are two sorts of these, viz. the bend-mould and hollow-mould; the former of these determines the convexity of the timbers, and the latter their concavity on the outside, where they approach the heel, particularly towards the extremities of the vessel. The figure given to the timbers by this pattern is called their bevelling.

Mould, in botany. See Mucor.

Mould, in mineralogy. See Mucus. The best mould for vegetables is that which contains a large proportion of carbonaceous or vegetable matter, intermixed with some portion of animal mould, as of church-yards, or muck strongly impregnated with ammonia, which is an animal substance. Moulds vary much in their colour: there are hazel moulds, dark-grey, russet, ash, yellowish-red, and many besides. The first three colours are generally regarded as denoting the best qualities, and the last as the most unfriendly to the growth of vegetables.

For the purpose of the gardener, those moulds which are capable of working well at all seasons, are somewhat light and dry, perfectly mellow and fine in their particles. See Com-

POST, BOTANY, SOIL, and CONVERTIBILITY.

To **MOULD.** *v. n.* (from the noun.) To contract concreted matter; to gather mould (*Bac.*).

To **MOULD.** *v. a.* To cover with mould; to corrupt by mould (*Knolles*).

To **MOULD.** *v. a.* (from the noun.) 1. To form; to shape; to model (*Wotton*). 2. To knead: as, to *mould* bread (*Ains.*).

MO'ULDABLE. *a.* (from *mould.*) That may be moulded (*Bacon*).

MO'ULDER. *s.* (from *mould.*) He who moulds.

To **MO'ULDER.** *v. n.* (from *mould.*) To be turned to dust; to perish in dust (*Clarendon*).

To **MO'ULDER.** *v. a.* (from *mould.*) To turn to dust; to crumble (*Pope*).

MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface, which, viewed through a microscope, appears like a kind of meadow, out of which arise herbs and flowers, some only in the bud, others full blown, and others decayed, each having its root, stalk, and other parts.

MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chisel, or the ax.

MOULDINGS, in architecture, projectures beyond the naked wall, column, wainscot, &c. the assemblage of which forms corniches, door-cases, and other decorations of architecture.

MO'ULDWARP. *s.* (molꝺ and ƿeoꞃpan, Saxon.) A mole; a small animal that throws up the earth (*Walton*).

MO'ULDY. *a.* (from *mould.*) Overgrown with concretions (*Addison*).

MOULINET, a French term properly signifying a little mill, being the diminutive of *moulin*, mill.

It is used in mechanics to signify a roller, which, being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature, to draw ropes, and heave up stones, timber, &c.

MOULINET is also a kind of turn-stile, or wooden cross, which turns horizontally upon a stake fixed in the ground; usually placed in the passages to keep out horses, and to oblige passengers to go and come one by one.

These moulinets are often set near the outworks of fortified places, at the sides of the barriers, through which people pass on foot.

MOULINS, a town of France, and capital of the department of the Allier. Before the revolution, it was the capital of the Bourbonnois, and is esteemed one of the pleasantest towns in France; it is situated on the Allier; the streets are broad and clean. The principal trade is cutlery. Near it is a medicinal spring: thirty-five posts and three quarters S.S.E. Paris. Lon. 3. 25 E. Lat. 46. 34 N.

MOULTAN, one of the most ancient cities of Hindustan Proper, capital of a province of the same name. It is of small extent for a capital, but strongly fortified, and has a Hindu temple of great celebrity. Here is a particular sect of Hindus, called Catry; a tribe of warriors supposed to be the Catheri or Cathei, with whom Alexander warred on the banks of the Malli. Moultan is seated on one of the branches of the Indus, 210 miles S.W. of Lahore, and 310 S.E. of Candahar. Lon. 70. 40 E. Lat. 29. 52 N.

To **MOULT.** *v. n.* (*muyten*, Dutch.) To shed or change the feathers; to lose feathers (*Suckling*).

MOULTING, a periodical change of plumage in birds. The term is also very appropriately used by Mr. Clark, of Edinburgh, to denote that natural process by which horses and other quadrupeds cast their hair. We shall follow that judicious writer in our remarks on this subject.

Horses, towards the end of autumn and beginning of winter, exhibit signs of some particular change about to take place in their constitutions; and this, at the same time, is attended with a degree of faintness or weakness mostly observed at that season. This, our author supposes, may arise from a variety of combined causes; but the principal one, he apprehends, may proceed from that of moulting; for, although horses in general do not cast their hair at this season as they do in the spring, yet, as a considerable change takes place in its thickness and length at this period, it may properly be called their moulting season. "Horses of all colours," says Buffon, "like most animals covered with hair, moult or cast their hair every year, commonly in the spring, and sometimes in the autumn. As they are then weaker than at any other period, they require more care, and should be more plentifully fed." The diseases that prevail at this period, in horses, are noticed by Mr. Clark as follows.

"As those horses," says he, "that are kept in warm stables, and well fed through the winter, are hearty and vigorous in the spring, when the season is gradually turning milder and warmer, their moulting at this season is not attended with that faintness, &c. to which they are liable on their moulting towards the end of autumn." The reason of this he attributes to the food of horses, which in the spring is dry, producing richer and better nourishment; also to the change of the season which then takes place, and which is more agreeable to their constitutions. Towards the end of autumn, he observes, it is very different with the generality of horses, and especially with those that have been fed with new hay, new grain, or late grass, and, at the same time, have undergone severe labour. Such kind of food, abounding too much with watery juices, produces less nourishment, and causes a general laxity of the muscular fibres of the whole body; and hence arises the increased languor and weakness so generally prevalent during the time of moulting.

"It is observed," continues this writer, "that horses kept in warm stables, and well fed, moult early in the spring; those that run abroad at grass moult much later. But if the former should be exposed to cold winds or rain for any length of time together, by being turned out to pasture, or otherwise exposed to cold weather, after they have once cast their winter coat, it appears that their hair will then grow thicker and longer, the same as it does in the beginning of winter, and continue so till the season grows milder, or that they are kept in warm stables: in this case, such horses may be said to have moulted twice in the spring."

The cold and moisture of the weather at this season, in Britain, are likewise adduced as a farther cause, contributing to increase this indisposition by occasioning a constriction of the pores of the skin; for at this period the hair of the generality of horses stares, whilst, at the same time, the skin is commonly dry and hard, or the animal is what is called hide-bound. They sweat, indeed, most profusely when put to any hard work, merely through weakness and relaxation; yet that natural insensible perspiration, which produces a shining and smooth appearance on the coat, seems to be almost suspended. Under such circumstances, they are disposed, upon any irregular management, to fall into diseases of various kinds. From the general constriction of their pores, that fluid which ought to pass off by insensible perspiration is retained; hence, the quantity of fluids in the vessels being increased whilst the muscular fibres through the whole system are relaxed, a deranged state of the circulation takes place, and hence proceed swellings of the legs, greasy heels, &c. so common at this season of the year.

On the other hand, horses that have had the early spring-grass, and are afterwards kept on hay, with a good allowance of grain, and daily accustomed to moderate exercise, suffer no material injury from moulting in the autumn, further than their being more liable to catch cold at this time, from the alternate changes they are exposed to, before their coats of hair have grown sufficiently thick to resist the cold.

Robust horses, at grass through the summer, if exposed to active exercises, are liable to many diseases about the time of moulting, as the interval from the time they are taken from grass, and the moulting, is too short to admit of their bodies being prepared to perform these exercises with safety to themselves. Hence they fall into that languor, &c. peculiar to this season; and, if left in the stable too much at rest, their gross habit of body disposes them to fever, disorders of the lungs, swelling of the legs and glands about the throat and jaws, and running sores, &c. nor are they able to undergo common exercises without being jaded.

Horses that run at grass through the summer and autumn are still in a worse situation. These are not only more liable to the foregoing diseases, from their very lax habit of body, but are less fit for active exercises of any kind, and require a longer time to be brought into a proper state. This period, in particular, proves critical with them, and, indeed, they generally fall victims to disease if too much worked.

It happens too, that in the situation above mentioned, the means required to render horses fit for active exercises, and to carry off the appearance of swelling of the legs, &c. are evacuations of every kind, such as bleeding, purging, diuretics, &c. At the same time, these methods are sometimes hurried on with a degree of haste that would even affect a sound horse, of the most hardy habit of body, at any season, and reduce him to great weakness. The moulting now approaches, which still adds to it. In these circumstances the constitution receives too great a shock to be resisted; and hence many horses fall a sacrifice to this treatment, or, if they survive, they are attacked with some chronic disorder, which renders them useless to their owners.

"The end of autumn," says Mr. Clark, "likewise proves very severe on those horses whose flesh and strength are exhausted from continued hard labour, or violent exercises, as posting, &c. through the summer and autumn: when the moulting comes on in this low, spiritless state of body, it carries off great numbers of them, that by proper care in moderating their labour, together with good nursing, and feeding them with rich boiled food at this time, their lives might be preserved. Such soft nourishing food becomes the more necessary for horses of this description at this particular period, in order to support them under the moulting, as the serous or watery parts of their fluids having been drained off by the violent perspiration they were exposed to, their muscular fibres are then too rigid, and the blood too thick for circulating so freely as it ought to do through the fine capillary vessels; hence they are disposed to fall into those disorders which proceed from this cause.

"Many of those horses that are thought to be worn out from posting, &c. at the end of autumn, when they come to be fed with boiled food, or with potatoes or carrots, and continued so through the winter, recover surprisingly. This last-mentioned food recovers their flesh; it renews their fluids in general, and promotes all the natural secretions: it operates on them nearly in the same manner as the spring-grass; it purges them gently on the first use of it, and corrects the whole habit. On changing their food to that which is hard and dry, as oats and beans, and increasing their exercise gradually towards the spring, they soon become fit for the most active exercises, without any previous preparation from medicine, &c.

"This season likewise proves destructive to aged horses: when the green food is exhausted, they are then obliged to feed on hard dry food; in some, the digestive powers may not only be weaker, but the teeth, at the same time, may be defective in not breaking down the hard food so minutely as it ought to be, in order to render it fit for digestion, and the nourishment of the body."

After illustrating this by a case in point, Mr. Clark proceeds to observe, that "As the disorders which commonly prevail at this time amongst horses proceed in a great measure from catching cold, together with the sickliness attending the moulting, horses are differently affected, according to circumstances of habit of body, and the treatment they may be exposed to; some are affected with colds in the head, attended with inflammation and swelling of the glands about the throat and jaws, which too frequently, from want of proper care, terminate in the glanders; hence this disorder is frequent at this season. Some horses are affected with coughs, and other disorders of the lungs. Rheumatism is likewise common in different parts of the body, particularly in the neck, which is called the chords. Epidemical diseases frequently originate at this period, and continue with more or less violence through the winter, and sometimes till towards the spring. Fever is likewise common, together with a variety of other complaints, which would be tedious to mention. All these disorders are forwarded from the above circumstances, together with horses breathing a heated foul air in their stables, and their bodies being exposed suddenly to the chillness of the weather, before their coats of hair have grown sufficiently thick to resist the cold, &c. for it is observed that horses which run abroad in the fields day and night moult much sooner in the season; by which means they are sufficiently guarded against the severity of the weather when it becomes cold and damp; neither is it remarked that they are so liable to be affected with those epidemical diseases which prevail amongst horses that are kept in too warm stables. This sickly disposition amongst them continues with more or less violence till such time as the weather turns more favourable and dry, or that the frost sets in. It commonly commences, if the weather be moist, cold, and damp, about the middle of October, and continues till towards the middle of December: after which, if it be favourable, horses generally turn more lively and vigorous, and acquire their usual spirit and healthy appearance, &c."

From what has been said, it may be observed, that as horses are generally more weakly at the time of moulting towards the end of autumn than at any other season, their labour, when circumstances will admit, should be moderate. "Their feeding should be increased, in order to strengthen and support them during this period. It ought likewise to be of the very best quality, as old hay, old grain, that is, of the preceding year's growth; and if the grain that is given them was broken down in a mill, it would prove more nourishing than in any other way it could be given them. New hay, or new grain of the same year's produce, ought to be avoided, as it is extremely hurtful to horses that must undergo severe labour or active exercises, of which we have formerly taken notice. Good rubbing and frequent dressing are likewise of great benefit.

"All evacuations, such as bleeding, purging, rowels, &c. ought to be administered with caution, as such prescriptions contribute greatly to increase that natural weakness, &c. formerly mentioned, which prevails in the constitution of horses at this period. At the same time it is to be understood, that horses are not by any means to stand too much at rest in the stable. Fresh air, with moderate exercise, when the weather will permit, being absolutely necessary to promote their health; neither is the proper use of the above prescriptions to be neglected when they are thought necessary, and prescribed with judgment. All the precautions formerly mentioned, with respect to their stables, ought to be attended to, that they are kept clean, well ventilated, and yet moderately warm. Body-cloths, however necessary they may be thought for keeping their coats of hair fine, smooth, and clean in the stable, ought to be dispensed with. As horses cannot with propriety be ridden with them, they must therefore be stripped the moment they are to go abroad, even although they should happen to be in a strong perspiration at the time; by which means they are liable to catch cold, &c. And surely the health of a horse is of much more consideration to his proprietor than the looks or appearance of his coat of hair, especially when it is considered, that good rubbing and frequent dressing will produce the same effect on the appearance of the hair. At the same time that this operation will in a great measure prevent the consequences above mentioned, of rendering horses so very liable to catch cold."

A single rug Mr. Clark thinks a sufficient covering for a horse whilst in the stable; and that more clothing than this may prove hurtful.

Moulting (Fox), is applied to birds. See Ornithology.

MOULTON (South), a corporate town in Devonshire, with a market on Saturday. It was anciently, with North Moulton, a royal demesne, and sent members to parliament in the reign of Edward I. It is governed by a mayor, and has manufactures of serges, shaloons, and felts. It is seated on the Moul, 12 miles S.E. of Barnstaple, and 177 W. by S. of London. Lon. 3. 55 W. Lat. 51. 5 N.

To MOUNCH. *To* Maunch. *v. a.* To eat.

MOUND, a term used for a bank, rampart, or other fence, particularly of earth.

Mound, or Mond, in heraldry, is a ball or globe with a cross upon it; such as our kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.

MOUNT, an elevation of earth, called also mountain.

The words mount and mountain are synonymous; but the former is scarce ever used in prose, unless when accompanied with some proper name; as Mount Ætna, Mount Gibel, Mount Lebanon, Mount Sinai, Mount Atlas, Mount Parnassus, &c.

To Mount. *v. n.* (*monter*, French.) 1. To rise on high (*Shakspeare*). 2. To tower; to be built up to a great elevation (*Job*). 3. To get on horseback (*Shaksp.*). 4. (for *amount.*) To attain in value (*Pope*).

To Mount. *v. a.* 1. To raise aloft; to lift on high (*Shaksp.*). 2. To ascend; to climb (*Dryden*). 3. To place on horseback (*Dry.*). 4. To embellish with ornaments. 5. *To* Mount *guard.* To do duty and watch at any particular post. 6. *To* Mount *a cannon.* To set a piece on its wooden frame for the more easy carriage and management in firing it.

MOUNT EDGECUMBE, a prodigious high peak, on the W. side of the entrance of Cook's Strait, in New Zealand. Its height is supposed not to be much inferior to that of the peak of Teneriff.

MOUNTMELLICK, a town of Ireland, in Queen's County. The wool-combing, malting, and tanning businesses, with the cotton manufacture, and bleaching, are carried on here. It is five miles N. of Maryborough, and 42 W.S.W. of Dublin.

MOUNTRATH, a town of Ireland, in Queen's County. Iron forges and furnaces have been long erected in its neighbourhood, but from the scarcity of charcoal have not been in regular use: the woollen manufacture forms the principal trade. It is six miles W.S.W. of Maryborough, and 23 N. of Kilkenny. Lon. 6. 54 W. Lat. 53. 2 N.

MOUNTSBAY, a bay on the south coast of Cornwall, between the Land's End and the Lizard Point. It is so named from a lofty peninsulated rock, called Mount St. Michael, which rises within it. Among the rocks, on this part of the coast, breeds the Cornish chough, or red-legged crow, noted for stealing and carrying away whatever it finds. In Mountsbay is a considerable pilchard fishery.

MOUNTSORREL, a town in Leicestershire, at the foot of a high mount or rock, of a sorrel-coloured stone, extremely hard. Of rough stones, hewn out of this rock, the buildings are erected the sand treet is paved. It has a market on Monday, and is seated on the Stour, 20 miles S.E. by S. of Derby, and 105 from London. Lon. 1. 9 W. Lat. 52. 45 N.

MOUNTS OF PIETY, certain funds or establishments in Italy, where money is lent out on some small security. There were also mounts of piety in England, raised by contribution for the benefit of people ruined by the extortions of the Jews.

MOUNTAIN (*mons*), a considerable eminence of land, elevated above every thing adjoining to it, and commanding all the surrounding places: it is commonly full of inequalities, cavities more or less exposed, and strata half laid open.

This name is likewise given to a chain of mountains; as when we speak of Mount Atlas in Africa; Mount Caucasus, which begins above Colchis and ends at the Caspian sea; the Pyrenean mountains, which separate France from Spain; and the Apennine mountains, which run through the whole of Italy.

Those who have surveyed the earth in general, and studied nature on a grand scale, have constantly been struck with admiration and astonishment at the sight of such majestic eminences, which, extending in different ways, seem to rule over the rest of the globe, and which present to the beholder a spectacle equally magnificent and interesting. In them it has been supposed we must search for a solution of the important problem regarding the creation of the world.

Naturalists reckon several kinds of mountains; and conjecture that these elevations of the earth have not all the same origin, nor date their commencement from the same era.

1. Those mountains which form a chain, and which are covered with snow, are considered as primitive or antediluvian. They are like majestic bulwarks scattered on the surface of the globe, and greatly exceed the other mountains in height. In general, their elevation is very sudden, and their ascent very steep and difficult. Their shape is that of a pyramid crowned with sharp and prominent rocks, on which no verdure is to be seen, but which are dry, naked, and as it were stripped of their soil, which has been washed away by the rains, and which present an awful and horrible aspect, sufficient to impress the coldest imagination with terror. These primitive mountains, which astonish the eye, and where wind only reigns, are condemned by nature to perpetual sterility. At the foot of them we frequently find paths less steep and winding than when we ascend to a greater height. They every where present thundering cascades, frightful precipices, and deep valleys. The depressions and excavations correspond with the quantity of water, the motion of which is accelerated in its fall, and which sometimes produces a total sinking or an inclination of the mountain. The wrecks to be found at the foot of most peaks show how much they have suffered from the hand of time. Nothing meets the eye but enormous rocks, heaped in confusion on one another, which prevent the approach of the human race. On the summits of these mountains or high eminences, which are only a series of peaks frequently detached from one another, the prominent rocks are covered with eternal snow and ice, and surrounded with floating clouds which are dispersed into dew. In a word, the rugged cliffs oppose an inaccessible rampart to the intrepidity of man; and nature exhibits a picture of disorder and decay. No shells or other organised marine bodies are to be found in the internal part of these primitive mountains: and though search has been made, by digging, on the tops of the Alps and the Pyrenees, no substances of this nature have yet been discovered, except on the sides near the base. Nothing is to be met with but continued rocks, caverns dug by the hand of nature, and abounding in crystallizations of great beauty, with various minerals. The stone of which they consist is an immense mass of quartz, somewhat varied, which penetrates into the bowels of the earth in a direction almost perpendicular to the horizon. We find no calcareous spar but in the fissures or rents which have some extent and an evident direction; and at great depths we find new parts as it were, or, in other words, the primitive state of things. All primitive mountains furnish proofs of these assertions. Of this kind in Europe are the Pyrenees, the Alps, the Apennines, the mountains of Tyrol, the mountain of the giants in Silesia, the Carpathian mountains, the mountains of Saxony, those of Norway, &c. In Asia we find the Riphean mountains, Mount Caucasus, Mount Taurus, and Mount Libanus: in Africa, the mountains of the Moon; and in America, the Apalachian mountains, and the Andes or Cordilleras. Many of the latter have been the seats of volcanos.

2. Another kind of mountains are those which are either detached, or surrounded with groups of little hills, the soil of which is heaped up in disorder, and the crust gravelly and confusedly arranged together. These are truncated, or have a wide mouth in the shape of a funnel towards the summit, and which are composed of, or surrounded with, heaps of calcined and half vitrified bodies, lava, &c. This class of mountains appear to have been formed by different strata raised up and discharged into the air, upon occasion of the eruption of some subterraneous fire. The isles of Santorin, Monte-Nuovo, Mount Etna, Adam's Peak in the island of Ceylon, the Peak of Teneriffe in the Canary Islands, and many others, have been formed in this manner. When very high mountains of this kind are covered with sea-shells, we may consider their summits as having once constituted a part of the bottom of the ocean. A number of these mountains have been formed in the memory of man; and present nothing to the view but disordered ruins, confused masses, parts heaped together in the greatest irregularity, and productions formed by eruptions or by the falling in of the earth. When a mountain of this kind is connected with the land, and advances farther into the sea than the adjoining country, it is then termed a Cape, Head, or Promontory; such as the Cape of Good Hope at the southern extremity of Africa. Mountains of the second rank are commonly more easy of access. Dr. Haller observes, that the angle formed between their base and their declivity is larger; that they have fewer springs; and that their plants are different from those of the Alps. The peasants in Swisserland, he tells us, are acquainted with the difference betwixt these two kinds of mountains.

3. Those mountains, whether arranged in a group or not, the earth or stone of which is disposed in strata more or less regular, and consisting of one or more colours and substances, are supposed to be produced by the substances deposited slowly and gradually by the waters, or by soil gained at the time of great floods. We daily see little hills formed in this manner, which are always of a small height compared with those of the first

order, and round in the top, or covered with soil frequently forming a pretty flat and extensive surface. We there find likewise sand and heaps of round pebbles, like such as have been worn by the waters. The internal part of these mountains consists of a heap of strata almost horizontal, and containing a prodigious quantity of shells, marine bodies, and fish-bones. Although these mountains formed by strata sometimes degenerate into little hills, and even become almost flat, they always consist of an immense collection of fossils of different kinds, in great preservation, and which are pretty easily detached from their earthy bed whether harder or softer. These fossils, consisting of marine shells intermixed and confounded with heaps of organized bodies of another species, present a picture of astonishing disorder, and give indubitable indications that some extraordinary and violent current has confounded and accumulated in the greatest disorder and precipitation foreign substances and shells of various kinds. These, removed from their natural and original place, by their union form an elevation and a mountain, which are in fact nothing but a composition of the wrecks of bodies formerly organized. All these phenomena seem to prove, that most of these mountains chiefly owe their origin to the sea, which once covered some parts of our continent, now left dry by its retreat. (According to the principles of this system, Anaxarchus explained the formation of the mountains of Lampsacus.) In these mountains we likewise find wood, prints of plants, strata of clay, marl, and chalk, different beds of stone succeeding one another, such as slate, marble which is often full of sea-shells, lime-stone which appears to be wholly formed from the wreck of shells, plaster-stone, entire strata of ochre, and beds of bitumen, mineral salt, and alum.

The strata of mountains which are lower and of a recent date, or formed by recent accidents, sometimes appear to rest upon, or to take their rise from, the sides of primitive mountains which they surround, and of which they in some measure form the first steps in the ascent; and they end by being insensibly lost in the plains. With respect to the irregularity of some strata in recent mountains, it is owing to violent and sudden inundations, to torrents, and to local revolutions which have produced angles, leaps, and sinkings down of the strata. See GEOLOGY.

A very ingenious writer, Dr. Kirwan, has lately published an interesting essay on the declivities of mountains, from which we present our readers with the following observations:

Among the various causes to whose activity the planet we inhabit owes its present wonderfully diversified appearance, some undoubtedly exerted their influence from its very origin, and others at subsequent periods; of these last one at least, namely, the Noachian deluge, was universal in its operation, while the effects of many more were partial and local, such as those resulting from earthquakes, volcanos, particular inundations, &c.

In a general survey of the globe, it is only to general causes, whose operation was universal, that our attention can be directed; the effects of partial causes being the proper objects of the geological history of those countries that were particularly affected by them.

But to distinguish causes of the former class from those whose operation was more confined, it is necessary to discover some character by which their effects may unequivocally be discerned.

Now a general uniformity, or agreement in some particular circumstance in every part of the globe, seems to be a sure test of the operation of some general cause. The discovery of uniform appearances is therefore of primary importance in geological researches. In the present essay Mr. K. confines himself to the investigation of one instance of this sort; namely, the inequality of declivity which the sides or flanks of mountains exhibit in every part of the globe hitherto examined according to the points of the compass to which they face, and are exposed.

That one part of almost every high mountain or hill is steeper than another, could not have escaped the notice of any person who had traversed such mountains; but that nature in the formation of such declivities had any regard to different aspects or points of the compass, seems to have been first remarked by the celebrated Swedish geologist Mr. Tilas, in the 22d vol. of the Memoirs of Stockholm for 1760. Neither Varenius, Lulolph, nor Buffon in his Natural History published in 1748, have noticed this remarkable circumstance.

The observation of Tilas however relates only to the extreme ends, and not to the flanks of mountains; with respect to the former, he remarked that the steepest declivity always faces that part of the country where the land lies lowest, and the gentlest that part of the country where the land lies highest, and that in the southern and eastern parts of Sweden they consequently face the E. and S.E. and in the northern the W. The essential part of this observation extends therefore only to the general elevation or depression of the country, and not to the bearings of these declivities.

The discovery that the different declivities of the flanks of mountains bear an invariable relation to their different aspects, seems to have been first published by Mr. Bergman in his physical description of the earth, of which the second edition appeared in 1773. He there remarked, that in mountains that extend from N. to S. the western flank is the steepest, and the eastern the gentlest. And that in mountains which run E. and W. the southern declivity is the steepest and the northern the gentlest, vol. 2d. § 187.

This assertion he grounds on the observations related in his first vol. § 32, namely, that 1° in Scandinavia the Suevoberg mountains that run N. and S. separating Sweden from Norway, the western or Norwegian sides are the steepest, and the eastern or Swedish the most moderate, the verticality or steepness of the former being to that of the latter as 40 or 50 to 4 or 2.

2dly. That the Alps are steeper on their western and southern sides than on the eastern and northern.

3dly. That in America the Cordelieres are steeper on the western side, which faces the Pacific Ocean, than on the eastern. But he does not notice a few exceptions to this rule in particular cases which will hereafter be mentioned.

Buffon, in the first vol. of his Epochs of Nature published in 1778, p. 185, is the next who notices the general prevalence of this phenomenon, as far as relates to the eastern and western sides of the mountains that extend from north to south, but he is silent with respect to the north and south sides of the mountains that run from east to west; nay, he does not seem to have had a just comprehension of this phenomenon, for he considers it conjointly with the general dip of the regions in which these mountains exist. Thus he tells us, vol. 1st, p. 185, that in all continents the general declivity, taking it from the summit of mountains, is always more rapid on the western than on the eastern side; thus the summit of the chain of the Cordelieres is much nearer to the western shores than to the eastern; the chain which divides the whole length of Africa, from the Cape of Good Hope to the mountains of the Moon, is nearer, he says, to the western than to the eastern seas; of this however he must have been ignorant, as that tract of country is still unknown.

The mountains which run from Cape Comorin through the peninsula of India are, he says, much nearer to the sea on the east than on the west; he probably meant the contrary, as the fact is evidently so, and so he states it in the 2d vol. p. 295; the same he tells us may be observed in islands and peninsulas, and in mountains.

This remarkable circumstance of mountains was notwithstanding so little noticed, that in 1792 the author of an excellent account of the territory of Carlsbad in Bohemia tells us he had made an observation, which he had never met with in any physical description of the earth, namely, that the southern declivity of all mountains was much steeper than the northern, which he proves by instancing the Erzgebirge of Saxony, the Pyrenees, the mountains of Switzerland, Savoy, Carinthia, Tyrole, Moravia, the Carpathian and Mount Hæmus in Turkey, 2, Bergm. Jour. 1792, p. 385, in the note.

Herman in his Geology, published in 1787, p. 90, has at least partially mentioned this circumstance, for he says that the eastern declivities of all mountains are much gentler and more thickly covered with secondary strata, and to a greater height, than the western flanks, which he instances in the Swedish and Norwegian mountains, the Alps, the Caucasian, the Appenine and Ouralian mountains; but the declivities bearing a southern or northern aspect he does not mention.

La Metherie, in the 4th vol. of his Theory of the Earth, of which the second edition appeared in 1797, a work which abounds in excellent observations, p. 381; produces numerous instances of the inequality of the eastern and western declivities, but scarce any of the northern and southern, whose difference he does not seem to have noticed, but he makes a remark which we have not seen elsewhere, that the coasts of different countries present similar declivities.

With regard to eastern and western aspects, he thinks that a different law has obtained in Africa from that which has been observed in other countries, for in that vast peninsula he imagines the eastern declivities of mountains are the steepest, and the western the gentlest. Of this however he adduces no other proof, than that the greatest rivers are found on the western side: this proof seems insufficient, as, if mountains be situated far inland, great rivers may flow indiscriminately from any side of them, and sometimes few rivers flow even from the side whose descent is most moderate, for instance, from the eastern side of the mountains of Syria; the Elbe and the Oder, two of the greatest rivers in Germany, take their course from the western sides, the first of the Bohemian and the other of the Moravian mountains, which yet are the steepest. Many originate from lakes, as the Shannon with us; many take such a winding course, that from a bare knowledge of the place of their disemboguement it is impossible to judge from what side of a mountain they issue, if from any; their course at most discovers the depression of the general level of the country.

In 1798, the celebrated traveller and circumnavigator, John Reinhold Foster, published a geological tract which merits so much more attention, as all the facts were either observed by himself, or related to him by the immediate observers. In this he states as a fact universally observed, that the south and south-east sides of almost every mountain are steep, but that the north and north-west sides are gently covered and connected with secondary strata in which organic remains abound, which he illustrates by various instances, some of which have been already, and others will presently be mentioned.

At present this fact attracts the greatest attention, being obviously connected with the original structure of the globe, and clearly proving that mountains are not mere fortuitous eruptions unconnected with transactions on the surface of the earth, as has of late been confidently advanced.

We shall now state the principal observations relative to this object, that have been made in different parts of the world.

In Europe.

1. The mountains that separate Sweden from Norway extend from north to south, their western sides are steep and the eastern gentle, 1. Bergm. Erde Beschreib. p. 157.

2. The Carpathian mountains run from E. to W. their southern sides towards Hungary are steep, their northern towards Poland moderate, Foster, § 46.

3. Dr. Walker, professor of natural history at Edinburgh, observed that the coasts and hills of Scotland are steeper and higher on the western side than on the eastern; Jamison's Mineralogy of Shetland, p. 3. However, Jamison observed, that the south side of the isle of Arran is the lowest, and the north side the highest, p. 51.

4. The mountains of Wales are gentle on the eastern and steep on the western sides.

5. The mountains of Parthery, in the county of Mayo, are steep on the western side.

6. The mountains which separate Saxony from Bohemia descend gently on the Saxon or northern side, but are steep on the Bohemian or southern side; Charpent, p. 75. The southern declivity is to the northern as six to two, 2d Bergm. Journ. 1792, p. 384 and 385.

7. The mountains which separate Silesia from Bohemia run nearly from E. to W. yet are steeper on the northern or Silesian side than on the opposite Bohemian; Assemanni Silesia, 335. Such branches as run from N.E. to S.W. have their western covered with primordial strata, and consequently less steep; 4. New Roz. p. 157.

8. The Meissener in Hessia is steeper on the N. and E. sides which face the Warra, than on the south and western; 1. Bergm. Journ. 1789, p. 272.

9. The mountains of the Hartz and Habichtswald are steep on the south and gentle on the northern sides, Foster, § 46.

10. The Pyrenees, which run from E. to W. are steeper on the southern or Spanish side; Carbonieres, XIII.

11. The mountains of Crim Tartary are gentle on the northern and steep on the southern sides, Foster, ibid.

In Asia.

12. The Ourals, which stretch from N. to S. are far steeper on the western than on the southern sides; Herman Geologie, p. 90, and 2d Ural Beschreib. p. 389.

13. The mountain of Armenic to the west of the Ourals is steep on its E. and N. sides, but gentle on the southern and western; 1. Pallas Voy. p. 277.

14. The Altaischan mountains are steep on their southern and western sides, but gentle on the northern and eastern; Foster, ibid. and Herman 2d. Ural Beschreib. p. 390, in the note.

15. So also are the mountains of Caucasus, 3d. Schrift. Berl. Geselsch. 471.

16. The mountains of Kamskatska are steep on the eastern sides, Pallas, 1 Act. Petropol. 1777, p. 43.

17. The Ghauts in the Indian peninsula are steep on the western sides.

18. The mountains of Syria which run from N. to S. skirting the Mediterranean, are said to be steeper on the western side facing the Mediterranean; 4. La Metherie, p. 380.

In America.

The Cordelieres run from N. to S. their western flanks towards the Pacific are steep, their eastern descend gradually.

In Guiana there is a chain of mountains that run from E. to W. their southern flanks are steep, their northern gentle; Voyages de Condamine, p. 140.

To assign the causes of this almost universal allotment of unequal declivities to opposite points, and why the greatest are directed to the west and south, and the gentlest on the contrary to the east and north, it is necessary to consider,

1. That all mountains were formed while covered with water.

2. That the earth was universally covered with water at two different æras, that of the creation, and that of the Noachian deluge.

3. That in the first æra we must distinguish two different periods, that which preceded the appearance of dry land, and that which succeeded the creation of fish, but before the sea had been reduced nearly to its preseet level; during the former, the primæval mountains were formed, and during the last, most of the secondary mountains and strata were formed.

4. That all mountains extend either from E. to W. or from N. to S. or in some intermediate direction between these cardinal points, which need not be particularly mentioned here, as the same species of reasoning must be applied to them as to those to whose aspect they approach most.

These preliminary circumstances being noticed, we are next to observe that during the first æra, this vast mass of water moved in two general directions, at right angles with each other, the one from E. to W. which needs not to be proved, being the course of tides which still continue, but were in that ocean necessarily stronger and higher than at present: the other from N. to S. the water tending to those vast abysses then formed in the vicinity of the south pole, as shewn in my former essays. Before either motion could be propagated, a considerable time must have elapsed.

Now the primæval mountains formed at the commencement of the first æra, and before this double direction of the waters took place, must have opposed a considerable obstacle to the motion of that fluid in the sense that crossed that of the direction of these mountains. Thus the mountains that stretch from N. to S. must have opposed the motion of the waters from E. to W. this opposition diminishing the motion of that fluid disposed it to suffer the earthy particles with which in those early periods it must have been impregnated, to crystallize or be deposited on these eastern flanks, and particularly on those of the highest mountains, for over the lower it could easily pass; these depositions being incessantly repeated at heights gradually diminishing as the level of the waters gradually lowered, must have rendered the eastern declivities or descent gentle, gradual, and moderate, while the western sides receiving no such accessions from depositions, must have remained steep and craggy.

Again, the primæval mountains that run from E. to W. by opposing a similar resistance to the course of the waters from N. to S. must have occasioned similar depositions on the northern sides of these mountains against which these waters impinged, and thus smoothed them.

Where mountains intersect each other in an oblique direction, the N. E. side of one range being contiguous to the S. W. flanks of another range, there the afflux of adventitious particles on the north-east side of the one must have frequently extended to the S. W. side of the other, particularly if that afflux were strong and copious; thus the Erzgebirge of Saxony, which run from W. to E. have their N. E. sides contiguous to the S. W. side of the Riesengebirge that separate Silesia from Bohemia, and hence these latter are covered with the same beds of gneiss, &c. as the northern sides of the Saxon, and thereby are rendered smooth and gentle comparatively to the opposite side, which being sheltered, remains steep and abrupt, which explains the seventh observation.

The causes here assigned explain why the covering of adventitious strata on the highest mountains is generally thinnest at the greatest height, and thickest towards the foot of the mountain; for the bulk of the water that contained the adventitious particles being proportioned to its depth, and the mass of earthy particles with which it was charged being proportioned to the bulk of water that contained them, it is plain, that as the height of water gradually decreased, the depositions from it on the higher parts of the mountains must have been less copious than on the lower, where they must have been oftener repeated.

Hence, 2. granitic mountains, generally the most ancient, frequently have their northern or eastern sides covered with strata of gneiss or micaceous shistus, and this often with argillite, or primæval sand-stone, or lime-stone, these being either of somewhat later formation or longer suspendible in water.

Hence, 3. different species of stone are often found at different heights of the same flank of a mountain, according as the water which conveyed these species happened to be differently impregnated at different heights; during its first æra its depositions formed the primitive stony masses, but after the creation of fish, lime-stone, sand-stone, farcilites, and secondary argillites, in which piscine remains are found, were deposited. But during the second æra, viz. that of the Noachian deluge, by reason of the violence and irregularity of its aggression, the depositions were more miscellaneous and are found at the greatest heights; yet in general they may well be distinguished by the remains of land animals, or of vegetables, or of both, which they present in their strata (or at least by the impressions of vegetables which they bear) as these must have been conveyed after the earth had been inhabited. But mountains regularly stratified bearing such remains, for instance the carboniferous, cannot be deemed to have been formed in a period so tumultuous. During this deluge the waters also held a different course, proceeding at first from south to north, and afterwards in both opposite directions.

Hence, and from various contingent local causes, as partial inundations, earthquakes, volcanos, the erosion of rivers, the elapsion of strata, disintigration, the disruption of the lofty mounds by which many lakes were anciently hemmed in, several changes were produced in particular countries that may at first sight appear, though in reality they are not, exceptions to the operations of the general causes already stated.

Thus the mountains of Kamskatska had their eastern flanks torn and rendered abrupt by the irruption of the general deluge, probably accompanied by earthquakes. And thus the Meissener had its E. and N. flanks undermined by the river Warra, as Werner has shewn; thus the eighth and sixteenth observations are accounted for, as is the thirteenth, by the vast inundations so frequent in this country, 1 Pallas, p. 172, which undermined or corroded its E. side, while the western were smoothed by the calcareous depositions from the numerous rivers in its vicinity.

Hence, 4. we see why on different sides of lofty mountains different species of stones are found, as Pallas and Saussure have observed, 2 Sauss. § 981, a circumstance which Saussure imagined almost inexplicable, but which Dolomieu has since happily explained, by shewing that the current which conveyed the calcareous substances to the northern, eastern, and north-eastern sides of the Alps, for instance, was stopped by the height of these mountains, and thus prevented from conveying them to the southern sides, and thus the north-eastern sides were rendered more gentle than the opposite, 3. New Rotz. p. 425, conformably to the theory here given.

Hence, 5. where several lofty ridges run parallel to each other, it must frequently happen that the external should intercept the depositions that do not surmount them, and thus leave the internal ridges steep on both sides.

Hence, 6. low granitic or other primitive hills are frequently uncovered by adventitious strata on all sides, as at Phanet in the county of Donegal, or are covered on all sides; the impregnated waters either easily passing over them, or stagnating upon them, according to the greater or less rapidity of its course, and the obstacles it met with.

The twofold motion of the ancient ocean is noticed both by Buffon and Bergman, but neither of them have deduced from it the true explanation of the phenomena of which we here treat: Buffon attributes the formation of secondary mountains to deposition or sediments from the sea after the existence of fish, 1. Epoques, p. 143, in 8vo. which he says invested the bases of mountains without noticing any distinction of sides, p. 144 and 170. He thinks these sediments were equally conveyed from both poles towards the equator, for it is the equatorial regions that he thinks those mighty caverns opened, towards which the primitive ocean was impetuously borne and in which it was ingulphed, p. 181, 182, and 183. If so, similar declivities should be formed on the southern as on the northern sides of mountains, which is contrary to the observed facts. His explanation of the eastern and western declivities is defective and erroneous, for he attributes the abruptness of the western sides to the erosion of the coasts on that side (an erosion that exists only in fancy) and the smoothness of the eastern to the gradual desertion and retreat of the sea on that side, p. 184 and 185, a retreat equally fictitious, as De Luc has well shewn. Whereas since the general motion of the sea is from E. to W. if the erosion were of either side it should rather be on the eastern than on the western; besides, if the gentle declivities of the eastern sides of mountains arose from the gradual retreat of the sea, the petrifactions of the secondary mountains thus formed should consist of such shell-fish as inhabit shallow seas or shores, whereas they consist chiefly of those called pelagicæ, which inhabit the greatest depths.

With respect to the eastern and western declivities, Mr. Bergman's account of the origin of their inequality agrees exactly with mine, 2. Bergm. Erdeklotet § 183 and 187, but he fails in accounting for the inequality of the northern and southern, for he supposes the course of the water to tend equally from both poles towards the æquator, which would render the depositions equal on both sides, which is contrary to observation.

Mountains (Height of). See Barometer.

Mountains (White). See New Hampshire.

Mountains of the Moon, a chain of mountains in Africa, extending themselves between Abyssinia and Monomotapa, and receiving the above denomination from their great height.

Mountains of the Lions, also in Africa, divide Nigritia from Guinea, and extend as far as Ethiopia. They were styled by the ancients the mountains of God, on account of their being greatly subject to thunder and lightning.

Mountain of Forty-days, a mountain of Judea, situated in the plain of Jericho to the north of that city. According to the Abbe Mariti's description, the summit of it is covered neither with shrubs, turf, nor earth; it consists almost entirely of a solid mass of white marble, the surface of which is become yellow by the injuries of the air.

Mo'untain. *a.* (*montanus*, Latin.) Found on the mountains; pertaining to the mountains; growing on the mountains (*Shakspeare*).

Mountain-ash, in botany. See Sorbus.

Mountain-blue, in mineralogy. See Cuprum.

Mountain-butter. See Alumen.

Mountain-cork, in mineralogy. See Asbestos.

Mountain-flax, in mineralogy. See Asbestos.

Mountain-green, in mineralogy. See Cuprum.

Mountain-leather, in mineralogy. See Asbestos.

Mountain-wood, in mineralogy. See Asbestos.

MOUNTAINE'ER. *s.* (from *mountain.*) 1. An inhabitant of the mountains (*Bentley*). 2. A savage; a freebooter; a rustic (*Milton*).

MO'UNTAINET. *s.* (from *mountain.*) A hillock; a small mount (*Sidney*).

MO'UNTAINOUS. *a.* (from *mountain.*) 1. Hilly; full of mountains (*Burnet*). 2. Large as mountains; huge (*Prior*). 3. Inhabiting mountains (*Bacon*).

MO'UNTAINOUSNESS. *s.* State of being full of mountains (*Brerewood*).

MO'UNTANT. *a.* (*montant*, Fr.) Rising on high (*Shakspeare*).

MO'UNTEBANK. *s.* (*montare* in *banco*, Italian.) 1. A doctor that mounts a bench in the market, and boasts his infallible remedies and cures (*Hudibras*). 2. Any boastful and false pretender (*Shaks.*).

To MO'UNTEBANK. *v. a.* (from the noun.) To cheat by false boasts or pretences (*Shakspeare*).

MO'UNTENANCE. *s.* Amount of a thing in space: obsolete (*Spenser*).

MO'UNTER. *s.* (from *mount.*) One that mounts (*Drayton*).

MO'UNTY. *s.* (*montée*, French.) The rise of a hawk (*Sidney*).

To MOURN. *v. n.* (muꞃnan, Saxon.) 1. To grieve; to be sorrowful (*Bacon*). 2. To wear the habit of sorrow (*Pope*). 3. To preserve appearance of grief (*Samuel*).

To MOURN. *v. a.* 1. To grieve for; to lament (*Addison*). 2. To utter in a sorrowful manner (*Milton*).

MOURNE. *s.* (*morne*, Fr.) The round end of a staff; the part of a lance to which the steel part is fixed (*Sidney*).

MO'URNER. *s.* (from *mourn.*) 1. One that mourns; one that grieves (*Shaksp.*). 2. One who follows a funeral in black (*Dryden*). 3. Something used at funerals (*Dryden*).

MO'URNFUL. *a.* (*mourn* and *full.*) 1. Having the appearance of sorrow (*Dryden*). 2. Causing sorrow (*Shakspeare*). 3. Sorrowful; feeling sorrow (*Prior*). 4. Betokening sorrow; expressive of grief (*Shakspeare*).

MO'URNFULLY. *ad.* Sorrowfully; with sorrow (*Shakspeare*).

MO'URNFULNESS. *s.* (from *mournful.*) 1. Sorrow; grief. 2. Show of grief; appearance of sorrow.

MO'URNING. *s.* (from *mourn.*) 1. Lamentation; sorrow (*Esdras*). 2. The dress of sorrow (*Dryden*).

MOURNING, a particular dress or habit worn to signify grief on some melancholy occasion, particularly the death of friends or of great public characters. The modes of mourning are various in different countries; as also are the colours that obtain for that end. In Europe, the ordinary colour for mourning is black; in China, it is white; in Turkey, blue or violet; in Egypt, yellow; in Ethiopia, brown. White obtained formerly in Castile on the death of their princes. Herrera observes, that the last time it was used was in 1498, at the death of prince John. Each people pretend to have their reasons for the particular colour of their mourning: white is supposed to denote purity; yellow, that death is the end of human hopes, in regard that leaves when they fall, and flowers when they fade, become yellow; brown denotes the earth, whither the dead return; black, the privation of life, as being the privation of light; blue expresses the happiness which it is hoped the deceased does enjoy; and purple or violet, sorrow on the one side, and hope on the other, as being a mixture of black and blue.

MOURNING, among the ancients, was expressed various ways. Amongst the Jews, on the death of their relations or intimate friends, grief or mourning was signified by weeping, tearing their clothes, smiting their breasts, or tearing them with their nails, pulling or cutting off their hair and beards, walking softly, i. e. bare-foot, lying upon the ground, fasting, or eating upon the ground. They kept themselves close shut up in their houses, covered their faces, and abstained from all work, even reading the law, and saying their usual prayers. They neither dressed themselves, nor made their beds, nor shaved themselves, nor cut their nails, nor went into the bath, nor saluted any body: so that sulkiness seems to have been an indication of sorrow; and dirtiness, of distress. The time of mourning among the Jews was generally seven days: though this was lengthened or shortened according to circumstances; but thirty days were thought sufficient upon the severest occasions. The different periods of the time of mourning required different degrees of grief, and different tokens of it.

The Greeks, on the death of friends, showed their sorrow by secluding themselves from all gaiety, entertainments, games, public solemnities, the enjoyment of wine, and the delights of music. They sat in gloomy and solitary places, stripped themselves of all external ornaments, put on a coarse black stuff by way of mourning, tore their hair, shaved their heads, rolled themselves in the dust and mire, sprinkled ashes on their heads, smote their breasts with their palms, tore their faces, and frequently cried out with a lamentable voice and drawling tone, reiterating the interjection, ε, ε, ε, ε; hence funeral lamentations were called Ελεγοι. If they appeared in public during the time of mourning, they had a veil thrown over their faces and heads. During the funeral procession, certain persons called εξαρχοι θρηνων marched before, and sung melancholy strains called ολοφυρμοι; ιαλεμοι, αινοι and αιλινοι. These vocal mourners sung thrice during the procession round the pile and round the grave. Flutes were also used to heighten the solemnity. At the funerals of soldiers, their fellow-soldiers who attended, as a testimony of their affliction, held their shields, their spears, and the rest of their armour, inverted.

As to the tokens of private grief among the Romans, they were the same as those already observed as customary amongst the Greeks. Black or dark-brown were the colours of the mourning habits worn by the men; they were also common to the women. The mourning of the emperors at first was black. In the time of Augustus, the women wore white veils, and the rest of their dress black. From the time of Domitian they wore nothing but white habits, without any ornaments of gold, jewels, or pearls. The men let their hair and beards grow, and wore no wreaths of flowers on their heads while the days of mourning continued. The longest time of mourning was ten months: this was Numa's establishment, and took in his whole year. For a widow to marry during this time was infamous. Mourning was not used for children who died under three years of age. From this age to ten they mourned as many months as the child was years old. A remarkable victory, or other happy event, occasioned the shortening of the time of mourning: the birth of a child, or the attainment of any remarkable honour in the family, certain feasts in honour of the gods, or the consecration of a temple, had the same effect. After the battle at Cannæ, the commonwealth decreed that mourning should not be worn for more than thirty days, that the loss might be forgot as soon as possible. When public magistrates died, or persons of great note, also when any remarkable calamity happened, all public meetings were intermitted, all places of concourse were shut up, and the whole city put on a face of sorrow. This also was the custom of Athens, and was even observed upon the death of Socrates, not long after he had been sentenced to death by their judges.

MO'URNINGLY. *ad.* (from *mourning*.) With the appearance of sorrowing (*Shaksp.*).

MOURZOUK, a city of Africa, and capital of the kingdom of Fezzan, situated on the banks of a small river, and well supplied with water by a multitude of wells and springs. It is surrounded by a high wall, which not only furnishes the means of defence, but affords to the government an opportunity of collecting, at its three gates, a tax on all goods (though provisions are exempted) that are brought for the supply of its people. Being formerly built with stone, it still retains the appellation of a Christian town, and the medley which it presents to the eye, of the vast ruins of ancient buildings, and of the humble cottages of earth and sand, that form the dwellings of its present Arab inhabitants, is singularly grotesque and strange: 262 miles S. Mesurata, and 940 N.E. Tombucto. Lon. 15. 5 E. Lat. 27. 20 N.

MOUSE. plural *mice. s.* (muꞅ, Sax.) The smallest of all beasts; a little animal haunting houses and corn-fields (*Derham*).

To MOUSE. *v. n.* (from the noun.) To catch mice (*Shakspeare*).

MOUSE, in mastiology. See MUS.

MOUSE-EAR, in botany. See HIERACHIUM.

MOUSE-TAIL. See MYOSURUS.

MOUSE (Dor). See MYOXUS.

MOUSE (Shrew). See SOREX.

MO'USEHUNT. *s.* (*mouse* and *hunt.*) Mouser; one that hunts mice (*Shakspeare*).

MO'USE-HOLE. *s.* (*mouse* and *hole.*) Small hole (*Stillingfleet*).

MO'USER. *s.* (from *mouse.*) One that catches mice (*Swift*).

MO'USE-TRAP. *s.* (*mouse* and *trap.*) A snare or gin in which mice are taken (*Hale*).

MOUSTACHE, in mastiology. See SIMIA.

MOUSUL, or MOSUL, a town of Asiatic Turkey, in the province of Diarbekir, situated in a plain, on the west bank of the Tigris, surrounded with walls and ditches, and defended with a castle. Almost all the houses are built of stone; the Tigris is deep and rapid, and is crossed by a bridge of boats. The air is healthy in spring, hot in summer, feverish in autumn, and inconveniently cold in winter. The inhabitants consist of Arabians, Turks, Persians, and Curds, all which languages are spoken. The Mahometans pay great respect to the tomb of one Dscherdschis, or George, whom they call a prophet. The Nestorian patriarch of Syria resides at Elkasch, near the town, where also are found many Christians, Arminians, Greeks, and Maronites. This city is not so flourishing as it has been; however, the inhabitants carry on considerable manufactures of cotton. Merchandize from India is brought hither by the way of Bassora, and European goods by the way of Aleppo: 240 miles E. Aleppo, and 480 W.N.W. Ispahan. Lon. 41. 15 E. Lat. 35. 40 N.

MOUTH. *s.* (muð, Sax.) 1. The aperture in the head of any animal at which the food is received (*Locke*). 2. The opening; that at which any thing enters; the entrance (*Arbuth.*). 3. The instrument of speaking (*L'Estrange*). 4. A speaker; a rhetorician; the principal orator (*Addison*). 5. Cry; voice (*Dryden*). 6. Distortion of the mouth; wry face (*Add.*). 7. *Down in the* MOUTH. Dejected; clouded in the countenance (*L'Estrange*).

MOUTH. (*os.*) In anatomy. The cavity of the mouth is well known. The parts which constitute it are the common integuments, the lips, the muscles of the upper and under jaw, the palate, two alveolar arches, the gums, the tongue, the cheeks, and salival glands. The bones of the mouth are the two superior maxillary, two palatine, the lower jaw, and thirty-two teeth. The arteries of the external parts of the mouth are branches of the infra-orbital, inferior alveolar, and facial arteries. The veins empty themselves into the external jugulars. The nerves are branches from the fifth and seventh pair. The use of the mouth is for mastication, speech, respiration, deglutition, suction, and taste.

Derham observes, that the mouth in the several species of animals is nicely adapted to the uses of such a part, and well sized and shaped for the formation of speech, the gathering and receiving of food, the catching of prey, &c. In some creatures it is wide and large, in others little and narrow; in some it is formed with a deep incisure into the head, for the better catching and holding of prey, and more easy communication of hard, large, and troublesome food; and in others with a shorter incisure, for the gathering and holding of herbaceous food. In birds it is neatly shaped for piercing the air; hard and horny, to supply the want of teeth; hooked in the rapacious kind, to catch and hold their prey; long and slender in those that have their food to grope for in moorish places; and broad and long in those that search for it in the mud. Nor is the mouth less remarkable in insects: in some it is forcipated, to catch, hold, and tear the prey; in others aculeated, to pierce and wound animals and suck their blood; in others, strongly rigid, with jaws and teeth, to gnaw and scrape out their food, carry burdens, perforate the earth, nay the hardest wood, and even stones themselves, for houses and nests for their young.

Mouth, in botany, the opening of the tube in the corol.

Mouth, in the manage. The external parts of the mouth are the lips, the beard, the end of the nose, being a continuation of the upper lip, and the chin. The internal parts are the bars, the tongue, the channel, the palate, and the teeth.

The mouth of a horse should be moderate in size; for when too wide, we find much difficulty to bit a horse, so as that he may not swallow it, as the term is: and, if he have a little mouth, it will be difficult to get the mouth of the bit rightly fixed in it.

To have a good mouth, a horse should have a well-raised neck; and if it be somewhat large and thick, it ought to be at least well turned. But if his jaw-bones be too close, and he have also a short and thick neck, so that he cannot place his head right, his having a good mouth will avail but little.

The compliance and obedience of a horse is owing, partly, to the tender or quick sense of his mouth, which makes him afraid of being hurt by the bit; and partly by his natural disposition and inclination to obey. The mouth is called sensible, fine, tender, light, &c. Some horses have so fine a mouth, that they stop if the horseman does but bend his body behind, and raise his hand, without staying for the pull or check of the bridle.

1. A mouth is said to be fixed and certain, when a horse does not chack or beat upon the hand.

2. A false mouth, is a mouth that is not at all sensible, though the parts look well, and are all well formed.

3. A mouth of a full appui, or rest upon the hand, is one that has not the tender nice sense of some fine mouths, but nevertheless has a fixed and certain rest, and suffers a hand that is a little hard, without chacking or beating upon the hand, without bearing down or resisting the bit, insomuch that he will bear a jerk of the bridle without being much moved.

For the army, provide a horse with a mouth that bears a full rest upon the hand; for, if you take one of a tender mouth, and another horse run against him in a fight, he will be apt to rise upon his hind-feet, which a horse of a harder mouth would not do.

4. A mouth that bears more than a full rest upon the hand, implies a horse that does not obey but with great difficulty. You will readily stop such a horse, for his mouth is above a full appui upon the hand.

To Mouth. *v. n.* (from the noun.) To speak big; to speak in a strong and loud voice; to vociferate (*Addison*).

To Mouth. *v. a.* 1. To utter with a voice affectedly big (*Shakspeare*). 2. To chew; to eat (*Shakspeare*). 3. To seize in the mouth (*Dryden*). 4. To form by the mouth (*Brown*).

MO'UTHED. *a.* (from *mouth.*) Furnished with a mouth (*Pope*).

MO'UTH-FRIEND *s.* (*mouth* and *friend.*) One who professes friendship without intending it (*Shakspeare*).

MO'UTHFUL. *s.* (*mouth* and *full.*) 1. What the mouth contains at once. 2. Any proverbially small quantity (*L'Estrange*).

MO'UTH-HONOUR. *s.* (*mouth* and *honour.*) Civility outwardly expressed without sincerity (*Shakspeare*).

MO'UTHLESS. *a.* (from *mouth.*) Being without a mouth.

MOUTH-PIECE. A little silver or brass appendage inserted at the end of the tube of a French-horn, or trumpet, to receive the pressure of the lips in performance.

MOW. *s.* (mope, Saxon, a heap.) A loft or chamber where hay or corn is laid up (*Tusser*).

To Mow. *v. n.* (from the noun.) To put in a mow.

To Mow. *v. a.* preter. *mowed*, part. *mown.* (maƿan, Saxon.) 1. To cut with a scythe (*Spenser*). 2. To cut down with speed and violence (*Shakspeare*).

To Mow. *v. n.* To gather the harvest (*Waller*).

Mow. *s.* (*mouë*, French.) Wry mouth; distorted face (*Shakspeare*).

To Mow. *v. n.* (from the noun.) To make mouths; to distort the face (*Ascham*).

To MO'WBURN. *v. n.* (*mow* and *burn.*) To ferment and heat in the mow for want of being dry (*Mortimer*).

MOWEE, one of the Sandwich islands discovered by Captain Cook, is 162 miles in circumference. A low isthmus divides it into two circular peninsulas, of which the eastern is double the size of the western. The mountains in both rise to an exceeding great height, and may be seen at the distance of more than 30 leagues. The northern shores, like those of Owyhee, afford no soundings, and the country presents the same appearance of verdure and fertility. Near the west point of the smaller peninsula is a spacious bay, with a sandy beach shaded with cocoa-nut trees. The country behind has a most romantic appearance, the hills rising almost perpendicularly in a great variety of peaked forms; and their steep sides and deep chasms between them are covered with trees. The tops of these hills are entirely bare, and of a reddish-brown colour. The number of inhabitants are computed at about 65,000. Lon. 175. 56 W. Lat. 20. 53 N.

MOWER. *s.* (from *mow.*) One who cuts with a scythe.

MOXA JAPONICA. (*Moxa*, Japanese.) A soft lanuginous substance, prepared in Japan, from the young leaves of a species of mugwort, by beating them when thoroughly dried, and rubbing them betwixt the hands, till only the fine fibres are left. Moxa is celebrated in the eastern countries, for preventing and curing many disorders, by being burnt on the skin; a little cone of it is laid upon the part, previously moistened, and set on fire on the top, burns down with a temperate and glowing heat, and produces a dark-coloured spot, the ulceration of which is promoted by putting a little garlic, and the ulcer either healed up when the eschar separates, or kept running for a length of time, as different circumstances may require. See ARTEMISIA.

MOYLE. See MULE.

MOZART (Wolfgang), the celebrated German musician, was born at Salzburg in the year 1756. His father was also a musician of some eminence.

At the age of three years, young Mozart, attending to the lessons which his sister, then seven years old, was receiving at the harpsichord, became captivated with harmony; and when she had left the instrument, he would instantly place himself at it, find the thirds, sound them with the liveliest joy, and employ whole hours at the exercise. His father, urged by such early and striking indications of genius, immediately began to teach him some little airs; and soon perceived that his pupil improved even beyond the hopes he had formed of him. Half an hour was generally sufficient for his acquiring a minuet or a little song, which, when once learned, he would of himself perform with taste and expression.

At the age of six years he had made such a progress as to be able to compose short pieces for the harpsichord, which his father was obliged to commit to paper for him. From that time nothing made any impression upon him but harmony; and infantine amusements lost all their attractions unless music had a share in them. He advanced from day to day, not by ordinary and insensible degrees, but with a rapidity which hourly excited new surprise in his parents—the happy witnesses of his progress.

His father returning home one day with a stranger, found little Mozart with a pen in his hand. "What are you writing?" said he. "A concerto for the harpsichord," replied the child. "Let us see it (rejoined the father); it is a marvellous concerto without doubt." He then took the paper, and saw nothing at first but a mass of notes mingled with blots of ink by the mal-address of the young composer, who, unskilled in the management of the pen, had dipped it too freely in the ink; and having blotted and smeared his paper, had endeavoured to make out his ideas with his fingers; but on a closer examination, his father was lost in wonder; and his eyes delighted and flowing with tears, became rivetted to the notes. "See (exclaimed he to the stranger) how just and regular it all is! but it is impossible to play it; it is too difficult." "It is a concerto (said the child), and must be practised till one can play it. Hear how this part goes." He then sat down to perform it; but was not able to execute the passages with sufficient fluency to do justice to his own ideas. Extraordinary as his manual facility was universally allowed to be for his age, it did not keep pace with the progress of his knowledge and invention. Such an instance of intellectual advancement, in a child only six years of age, is so far out of the common road of nature, that we can only contemplate the fact with astonishment, and acknowledge, that the possible rapidity of mental maturation is not to be calculated.

In the year 1762, his father took him and his sister to Munich, where he performed a concerto before the elector, which excited the admiration of the whole court: nor was he less applauded at Vienna, where the emperor called him the little sorcerer.

His father gave him lessons only on the harpsichord; but he privately taught himself the violin; and his command of the instrument afforded the elder Mozart the utmost surprise, when he one day at a concert took a second violin, and acquitted himself with more than passable address. True genius sees no obstacles. It will not therefore excite our wonder, if his constant success in whatever he attempted begot an unbounded confidence in his own powers; he had even the laudable hardihood to undertake to qualify himself for the first violin, and did not long remain short of the necessary proficiency.

He had an ear so correct, that he felt the most minute discordancy; and such a fondness for study, that it was frequently necessary to take him by force from the instrument. This love of application never diminished. He every day passed a considerable time at his harpsichord, and generally practised till a late hour at night. Another characteristical trait of real genius; always full of its object, and lost as it were in itself.

In the year 1763 he made, with his father and sister, his first grand musical journey. He visited Paris; and was heard by the French court in the chapel-royal at Versailles, where his talent on the organ was admired even more than on the harpsichord. At Paris the musical travellers gave two concerts, which procured them the highest reputation, and the distinction of public portraits. It was here that a set of sonatas for the harpsichord, some of his earliest compositions, were engraved and published.

From Paris they went to London, where they also gave two concerts, consisting of symphonies composed by young Mozart, who even at that early age sang also with much expression, and practised publicly with his sister. Mozart played already at sight, and in a concert, at which the king was one of his auditors, a bass being placed before him as a ground, immediately applied to it a most beautiful melody. Those who are best acquainted with the extent of such a task will be the most astonished at such mature familiarity with the intricacies of the science, and such prompt and ready invention in so juvenile a mind.

From London, where Mozart also published six sonatas for the harpsichord, the musical family went to Holland, thence again to France, and in 1766 returned to Salzburg. There this extraordinary youth remained more than a year in perfect repose; devoting the whole of his time to the study of composition, the principles of which he scrutinized with the depth and penetration of confirmed manhood. Emmanuel Bach, Hasse, and Handel, were his chief guides and models; though he by no means neglected the old Italian masters.

In 1768 he again visited Vienna, where Joseph II. engaged him to set to music a comic opera, entitled, La Finta Semplice, which obtained the approbation of Hasse and Metastasio. At the house of the prince of Kaunitz, it often happened that the first Italian air which came to hand would be given him, that in the presence of the company he might add to it accompaniments for numerous instruments; which he would write in the first style of excellence, and without the least premeditation. This is at once a proof with what acuteness of observation he had listened to the music of the best masters; how intimate he had already rendered himself with the characters, capacities, and effects of the different instruments; and what skill he had acquired in that abstruse art of mixed combination which, while it calculates the conjoint effect of sounds, as they regard the established laws of harmony, accommodates the different parts to the scales, tones, and powers of the respective instruments by which they are to be executed. It was at this time also that, although but twelve years of age, he composed the music for the consecration of the church of orphans, at the performance of which he himself presided.

In 1769 Mozart again returned to Salzburg, where he became maitre de concert. Not having yet seen Italy, in December of the same year he set out for that seat of the fine arts. Those talents which had already excited the admiration of Germany, France, and England, now awakened in that land of musical taste the most lively enthusiasm.

In 1771 he had no sooner given personal proofs of his genius, than *la scrittura* for the following carnival was conferred upon him. He visited Bologna, then as famous for harmonic excellence as Naples, where the celebrated theorist Martini was amazed to see a German boy work and execute the theme of a fugue which he presented to him, in the extraordinary style in which Mozart acquitted himself. He next went to Florence. Florence even enhanced the eulogiums which Bologna had lavished upon him.

During the holy week he arrived at Rome, and assisted at the Miserere in the Sixtine chapel; which performance is justly considered as the *ne plus ultra* of vocal music. This circumstance claims particular notice, as inducing a proof of another faculty of his mind, only to be equalled by those wonderful powers which he had already demonstrated. He was prohibited from taking a copy of this Miserere, and therefore piqued himself on retaining it in his memory. Having heard it with attention, he went home, made out a manuscript from recollection, returned the next day to the chapel, heard the piece a second time, corrected the rough draught, and produced a transcript, which surprised all Rome. This Miserere formed a scorer numerous in its parts, and extremely difficult of execution. His mind had embraced and retained the whole!

He soon after received from the pope the order of the gilt spur; and at Bologna was complimented, by an unanimous decision, with the title of member and master of the Philharmonic Academy. As a proof, *pro forma*, of his qualifications for this academical honour, a fugue, for four voices, in the church style, was required of him, and he was shut up alone in his chamber. He completed it in half an hour, and received his diploma. This evinced that he possessed an imagination constantly at his command, and that his mind was stored with all the riches of his beloved science.

The opera which he composed for Milan was called Mithridates. This piece procured him *la scrittura* for the grand opera of the carnival of 1773, which was his Lucio Sulla. At length, after a tour of fifteen months, he returned to Salzburg.

In 1771 Mozart visited Paris; but not relishing the music of that capital, he soon quitted it, and returned to his domestic comforts. In 1781, at the request of the elector of Bavaria, he composed the opera of Idomeneo for the carnival of that year. The general merit of this opera is so great, that it might serve alone for the basis of a distinguished reputation. At his twenty-fifth year he was invited to Vienna, where he continued spreading, as from a centre, the taste of his compositions through all Germany, and the lustre of his name over the whole of Europe.

Of all the virtuosi of the piano forte who then crowded Vienna, Mozart was much the most skilful. His finger was extraordinarily rapid and tasteful, and the execution of his left hand exceeded every thing that had before been heard. His touch was replete with delicacy and expression; and the profound study he had bestowed on his art, gave his performance a style the most brilliant and finished. His compositions had a rapid circulation; and in every new piece the connoisseurs were struck with the originality of its cast, the novelty of the passages, and the energy of the effect.

Joseph II. solicitous for the perfection of the German opera, engaged Mozart to compose a piece. He accordingly produced L'enlevement du Serail; performed for the first time in 1782. It excited the jealousy of the Italian company, who therefore ventured to cabal against it. The emperor, addressing himself to the composer, said, "It is too fine for our ears, my dear Mozart, and most charmingly crowded with notes." "Precisely what it ought to be," replied the spirited musician, who justly suspected that this remark had been suggested to Joseph by the envious Italians. “ Though I cannot describe, as an auricular evidence, (says the faithful author of the biography), the applauses and the admiration which this opera produced at Vienna, yet I have witnessed the enthusiasm it excited at Prague among all the connoisseurs, as well as among those whose ears were less cultivated. It was said, that all which had been heard before was not music: it drew the most overflowing audiences: every body was amazed at its new traits of harmony, and at passages so original, and till then so unheard from wind instruments.”

During the composition of this opera, he married Mademoiselle Weber, a distinguished virtuosa; and the piece was supposed to owe to this felicitous circumstance much of that endearing character, that tone of tenderness, and that expression of the softer passions, which form its principal attractions.

The Marriage of Figaro, which was in the highest repute at all the theatres, was in the year 1787 transformed into an Italian opera; and Mozart, at the instance of the emperor, set it to music. This piece was highly received every where, and kept possession of the theatre at Prague during almost the whole of the winter in which it first appeared: numerous extracts were made from it, and the songs and dances of Figaro were vociferated in the streets, the gardens, and the taverns. Mozart came that very winter to Prague, and performed in public on the piano forte. His auditors at all times listened to him with admiration; but whenever he played extempore, and indulged the spontaneous and uninterrupted sallies of his fancy, which he sometimes would for more than half an hour, every one was seized with the most enthusiastic raptures, and acknowledged the unrivalled resources of his imagination. About this time the manager of the theatre contracted with him for the composition of a new opera, which, when produced, was called Il dissoluto Punito, or Don Giovanni. His reputation was now so exalted, that the Bohemians piqued themselves on the circumstance that this opera was composed for their entertainment.

But this fame, this great and universal applause, had not yet produced to the admired artist any solid advantages; he had obtained no place, no settled income; but subsisted by his operas, and the instructions and occasional concerts which he gave. The profits of these proved insufficient for the style which he was obliged to support; and his finances became much deranged. The critical situation in which he now found himself made him resolve to quit Vienna, and seek an asylum in London; to which metropolis he had often been invited: but Joseph nominating him *compositeur de la chambre*, though with a very inadequate salary, he was induced to accept it; and Germany had the advantage of retaining him.

It is lamentable that premature genius too rarely enjoys a long career: the acceleration of nature in the mental powers seems to hurry the progress of the animal œconomy, and to anticipate the regular close of temporal existence.

In the year 1791, Mozart, just after he had received the appointment of *Maitre de chapelle* of the church of St. Peter, and when he was only thirty-five years of age, paid the last tribute; and left the world at once to admire the brilliancy and lament the shortness of his earthly sojournment.

Indefatigable, even to his death, he produced, during the last few months of his life, his three great master-pieces, La Flutte Enchantée, La Clemence de Titus, and a Requiem, his last production. La Flutte Enchantée was composed for one of the theatres at Vienna; and no dramatic olio could ever boast a greater success. Every air struck the audience with a new and sweet surprise; and the *tout ensemble* was calculated to afford the deepest and most varied impressions. This piece had, in fact, so great a number of successive representations, that for a long time it was unnecessary to consult the opera-bill; which only announced a permanent novelty. And the airs selected from it, and repeated throughout the empire, as well in the cottage as in the palace, and which the echoes have resounded in the most distant provinces, favoured the idea that Mozart had actually the design to enchant all Germany with his Flutte Enchantée.

La Clemence de Titus was requested by the states of Bohemia for the coronation of Leopold. The composer began it in his carriage during his route to Prague, and finished it in eighteen days.

Some circumstances attending the composition of the piece which we have already mentioned as the last effort of his genius, are too interesting to be omitted. A short time before his death, a stranger came to him with the request that he would compose, as speedily as possible, a requiem for a catholic prince, who, perceiving himself on the verge of the grave, wished, by the execution of such a piece, to soothe his mind, and familiarise it to the idea of his approaching dissolution. Mozart undertook the work; and the stranger deposited with him as a security 400 ducats, though the sum demanded was only 200. The composer immediately began the work, and during its progress felt his mind unusually raised and agitated. He became at length so infatuated with his requiem, that he employed not only the day, but some hours of the night in its composition. One day, while he was conversing with Madame Mozart on the subject, he declared to her that he could not but be persuaded that it was for himself he was writing this piece. His wife, distressed at her inability to dissipate so melancholy an impression, prevailed on him to give her the score. He afterwards appearing somewhat tranquillized, and more master of himself, she returned the score to him, and he soon relapsed into his former despondency. On the day of his death he asked for the requiem, which was accordingly brought to his bed: "Was I not right (said he), when I declared that it was for myself I was composing this funeral piece?" And the tears trickled from his eyes. This production of a man, impressed during its composition with a presentiment of his approaching death, is unique in its kind, and contains passages which have frequently drawn tears from the performers.

Only one complaint escaped him during his malady: "I must quit life (said he), precisely at the moment when I could enjoy it free from care and inquietude; at the very time when, independent of sordid speculations, and at liberty to follow my own principles and inclinations, I should only have to write from the impulses of my own heart: and I am torn from my family just when in a situation to serve it." Mozart, at the time of his death, was considerably involved in debt; but Vienna and Prague disputed the honour of providing for his widow and children.

The countenance of this great master did not indicate any thing uncommon. He was small of stature; and, except his eyes, which were full of fire, there was nothing to announce superiority of talent. His air, unless when he was at the harpsichord, was that of an absent man. But when he was performing, his whole physiognomy became changed: a profound seriousness recalled and fixed his eyes; and his sentiments were expressed in every movement of his muscles. Never has a musician more successfully embraced the whole extent of his art, and shone with greater lustre in all its departments. His great operas no less than his most simple songs; his learned symphonies as well as his airy dances—all carry the stamp of the richest imagination, the deepest sensibility, and the purest taste. All his works develope the originality of his genius; and imply a mind great and exalted; an imagination which strikes out for itself a new course. He therefore merits to be ranked with that small number of original geniuses, those *phœnomena splendida* who form an epoch in their art, by carrying it to perfection, or giving it an unknown career.

It is in the employment of wind instruments that Mozart displays his greatest powers. His melody is always simple, natural, and full of force; and expresses with precision the sentiments and individual situations of his personages. He wrote with extraordinary facility. La Clemence de Titus, the reader will recollect, cost him the study of but eighteen days; and his requiem, which is equal in length to an opera, was produced in four weeks. It is also worthy of remark, that the overture to his Don Giovanni was not begun till the night before the piece was to be performed. At midnight, after having devoted the evening to amusement, he locked himself up in his study, and composed it in a few hours. His memory was wonderfully retentive, as we may judge from his copying by recollection the miserere at Rome. But a fact equally astonishing is, that, soon discovering the eagerness of people to procure his works, and fearful they might be pirated, it was his constant custom to transcribe from the scores of his sonatas only a part for one hand, and at the public performance to supply the other by memory.

He very early began to display that true dignity of an artist which renders him indifferent to the praises of those who are unqualified to judge. The commendations of the ignorant great he never considered as fame. His hearers, whether the wealthy or the titled, must have acquired some credit for their judgment before he could be ambitious of their applause. Indeed he entertained so just a sense of scientific elevation and importance, that he would insist upon respect. And the least noise or idle babble, while he was at the instrument, excited a displeasure which he was too indignant to conceal. Once, to the honour of his feelings, he suddenly rose from his seat, and left his inattentive auditory to experience the keen though silent reproach of insulted genius.

His mind was by no means unlettered; nor was it embellished with one science alone. He was master of several languages, and had made considerable progress in the mathematics. He was honest, mild, generous, full of frankness; and with his friends had an air at once amiable, gay, and free from the least tincture of pedantry.

Far from viewing with envy the success of others, a weakness too closely interwoven in the general nature of man, he was always just to the talents of his fellow professors, and valued and respected merit wherever he found it; a clearer proof of which cannot be adduced than the following circumstance: at a concert, where a new piece composed by the celebrated Joseph Haydn was performed, a certain musician, who never discovered any thing worthy of praise except in his own productions, did not fail to criticise the music; exclaiming to Mozart, "There now! there again! why, that is not what I should have done:" "No; neither should I (replied Mozart); but do you know why? Because neither you nor I should have been able to conceive it."

MUCA'GE. (from *mucus*.) Mucilage.

MUCH. *a.* (*mucho*, Spanish.) 1. Large in quantity; long in time (*Deut.*). 2. Many in number (*Shakspeare*).

MUCH. *ad.* 1. In a great degree; by far (*Hebrews*). 2. To a certain degree (*Mark*). 3. To a great degree (*Baker*). 4. Often, or long (*Granville*). 5. Nearly (*Temple*).

MUCH. *s.* 1. A great deal; multitude in number; abundance in quantity (*Dryden*). 2. More than enough; a heavy service or burden (*Milton*). 3. Any assignable quantity or degree (*South*). 4. An uncommon thing; something strange (*Tillotson*). 5. *To make* MUCH *of.* To treat with regard; to fondle; to pamper (*Sidney*).

MUCH *at one.* Nearly of equal value; of equal influence (*Dryden*).

MU'CHWHAT. *ad.* (*much* and *what.*) Nearly (*Atterbury*).

MU'CHEL. *a.* for *muckle* or *mickle*, (mycel, Saxon.) Much (*Spenser*).

MU'CID. *a.* (*mucidus*, Latin.) Slimy; musty.

MU'CIDNESS. *s.* (from *mucid.*) Sliminess; mustiness (*Ainsworth*).

MUCILAGE. (*mucilege*, French, from *mucus*, *muci*, Latin; *der schleime*, German.) A peculiar secretion from certain organs of animals and vegetables, the chemical properties of which are the following: it is insipid, highly soluble in water, giving it a thick clammy appearance and feel; insoluble in alkohol; not coagulated by a boiling heat, nor crystallizable, and, after the watery solution has been evaporated to dryness, again soluble in water, without having undergone any material change.

The mucilage of animals appears to be somewhat more albuminous than that of vegetables, and hence they are now generally and correctly distinguished by appropriating the French name of *mucilege* to the vegetable secretion, and the Latin name of *mucus* to the animal. See MUCUS, as also GELATIN.

Vegetable mucilage is contained in every plant that has been hitherto analysed, in some parts more abundantly than in others, as also in some ages, and varying from other circumstances. It appears to be one of the elementary vegetable constituents, and probably by its decomposition in the organs of the plant it is converted into other substances; since it is often extremely abundant in the earlier age of the plant, and lessens as other principles are elaborated.

Mucilage is sometimes found nearly pure exuding from the bark and twigs of many vegetables, by natural and artificial clefts, and hardening in the sun into brittle, nearly transparent, roundish lumps. In this state it may be called gum mucilage. The purest of these gum mucilages are gum-arabic, or gum-senegal, which forms a very valuable article of commerce to the countries that yield it. An inferior sort is often obtained from cracks in plum, peach, pear, and other fruit trees, which is usually of a somewhat deeper colour than amber.

The gum-arabic tree is a species of mimosa (see MIMOSA) which grows in various climates, but especially and abundantly along the whole of the Barbary coast, and particularly about the river Senegal. The gum which makes its appearance about the middle of November, after the soil has been thoroughly saturated with periodical rains, is at first seen to ooze through the trunk and branches; about a fortnight after which it hardens into roundish drops of a yellowish-white, which are beautifully brilliant when they are broken off, and entirely so after being held in the mouth for a short time to dissolve the outer surface: no clefts are made, nor any artificial means used by the Moors to solicit the flow of the gum. The lumps of gum-senegal are usually about the size of partridge-eggs, and the harvest continues about six weeks. The quantity annually sold out of the Senegal country for European consumption is about twelve hundred thousand pounds weight.

This gum is also a very wholesome and nutritious food, thousands of the Moors supporting themselves entirely upon it during the time of harvest. About six ounces is sufficient nutriment for a day; and it is besides mixed with milk, animal broths, and other foods.

The gum-arabic, or that which comes directly from Egypt and the Levant, only differs from the preceding in being of a lighter colour and in smaller lumps: it is also somewhat more brittle.

To obtain gum mucilage from those vessels that do not yield it by exsudation, recourse must be had to boiling with water, and evaporation. These kinds of mucilage, however, will seldom answer as cements, for they will not sufficiently harden by drying, and are more liable to mould, and to become brown and coloured during the requisite evaporation.

Lord Dundonald has obtained gum mucilage from the lichen by the following means.—The lichen employed is the large-leaved moss that grows so abundantly on forest and fruit trees: this, in the north of Europe and in America, grows to the length of a foot or more, giving a nutritious food to deer and other animals. It has an outer skin, and below this is a green resinous substance; the remainder of the plant consists chiefly of gum and of fibrous matter, on which gum has no action. To separate the outer skin and the resinous matter, the plant must be scalded two or three times with boiling water, by means of which the skin will crack, swell, and peel off. After this the remaining substance is to be put into a boiler, with about three quarts of water for every pound of the plant, and about half an ounce of pot-ash or soda, (which assists the extraction) and the boiling should be continued till the liquor acquires a considerable degree of gummy consistence. The liquor is then to be taken out and strained from the plant, and fresh water added to the same material further to exhaust the gum. The several liquors after standing some hours to settle, and then removing the dregs, are to be boiled down in a regulated heat, to the consistence which is required for use, but not further, lest they should burn and become coloured. It requires two, and even three boilings entirely to exhaust the lichen of its mucilage.

Another species of native mucilage, somewhat differing from the preceding, is gum tragacanth. This is a white opake gum in the form of twisted shreds, seldom free from visible impurities, and of a considerably tough, often horny, consistence, so that it cannot be reduced to fine powder without considerable labour. It exsudes from the stem and branches of a very thorny shrub, the astragalus traga cantha of Linnéus, which grows on the island of Candia, and in other parts of the Levant. The juice dries in the sun, and being collected by the shepherds is sent to Europe without any preparation. It differs from gum-arabic in being, properly speaking, hardly soluble in water; but when it is covered with water it swells prodigiously in the course of a few hours, and absorbs so much of the fluid, as to become soft and pulpy, but will not resolve itself into a liquid by any further addition of water. In this soft pulpy state, it will readily mix with other mucilages, and may be spread thin over any surface, and it then dries into a very firm cement. It is employed much in book-binding mixed with paste, and is found to make a very strong cement.

Chemical properties of Mucilage.—When gum-arabic or other mucilage is distilled per se in vessels arranged so as to detain all the products, there first comes over some pure water, and immediately follows a reddish-brown acid liquor, mixed with a little brownish oil, and much carbonic acid gass, and carburetted hydrogen. This acid liquor is very sour to the taste, has an empyreumatic smell, and has been called the pyromucous acid. The same acid is obtained by the distillation of sugar, farina, and many other vegetable matters.

The action of the nitric acid upon gum mucilage has excited some attention, on account of the many new products produced by the mutual decomposition of these substances, and particularly the formation of a peculiar acid the mucous, which is thus simply called and distinguished from the pyromucous, in consequence of this last being altogether produced by the action of fire, while the mucous is obtained without it. This last is found to be the same as that discovered by Scheele, to be produced by the action of nitric acid on sugar of milk, and which was by him denominated saccho-lactic acid. See the article MILK.

A close and intimate connection has been supposed to exist between mucilage and sugar, partly from the existence in each of the principle of the pyromucous acid, and partly from other facts. Mr. Cruikshank however conceived sugar to be a substance of intermediate oxygenation, between mucilage and vegetable acids. Hence it ought to follow that each is convertible into the other by a due addition or abstraction of oxygen, supposing that the processes of nature can be at all imitated in the laboratory. We possess many proofs that sugar is formed out of mucilage in natural processes: that of germination is one; and sugar plants themselves, at an early period of their growth, contain mucilage alone. By a disoxygenating method, Mr. C. appears very successfully to have converted sugar into gum: but the converse experiment did not succeed, for it was found that gum could not be converted into sugar by any oxygenating process; nitric and oxymuriatic acids forming acids alone with gum, and not saccharine matter.

MUCILA'GINOUS. *a.* (*mucilagineux*, French; from *mucilage.*) Slimy; viscous; soft with some degree of tenacity (*Grew*).

MUCILAGINOUS EXTRACTS, in pharmacy, extracts that readily dissolve in water, scarcely at all in spirits of wine, and undergo spirituous fermentation.

MUCILA'GINOUSNESS. *s.* (from *mucilaginous.*) Sliminess; viscosity.

MUCILAGO, in botany, a genus of the class cryptogamia, order fungi, consisting of most simple, fugacious filaments. Four species:

1. M. plumosa; snow white, feathery.
2. M. cœspitosa; yellow, feathery.
3. M. cinerea; grey; tufted, branched and simple.
4. M. miniata; deep-red, villous.

MUCILAGO AMYLI. A preparation of starch mostly exhibited with opium in the form of glysters in diarrhæas and dysenteries, where the tenemus arises from an abrasion of the mucus of the rectum.

MUCILAGO ARABICI GUMMI. A demulcent preparation, more frequently used to combine medicines than in any other form.—In the recent London Pharmacopœia this is called mucilago acaciæ, and, with the preceding, forms the only mucilages retained.

MUCILAGO SEMINIS CYDONII MALI. The best form of exhibiting quince seeds as a demulcent.

MUCILAGO TRAGACANTHÆ. In tickling coughs, joined with syrup of mulberries, this forms a pleasant demulcent, and may be exhibited to children, who are very fond of it.

MUCK. *s.* (meox, Saxon.) 1. Dung for manure of grounds (*Glanville*). 2. Any thing low, mean, and filthy (*Spenser*). 3. *To run a* MUCK, signifies, To run madly and attack all that we meet (*Pope*).

To MUCK. *v. a.* To manure with muck; to dung (*Tusser*).

MU'CKENDER. *s.* (*mouchoir*, French.) A handkerchief (*Dorset*).

To MU'CKER. *v. n.* (from *muck.*) To scramble for money; to hoard up (*Chaucer*).

MU'CKERER. *s.* (from *mucker.*) One that muckers.

MU'CKHIL. *s.* (*muck* and *hill.*) A dunghil.

MU'CKINESS. *s.* (from *mucky.*) Nastiness; filth.

MU'CKLE. *a.* (mycel, Saxon.) Much.

MU'CKWORM. *s.* (*muck* and *worm*). 1. A worm that lives in dung. 2. A miser; a curmudgeon (*Swift*).

MU'CKY. *a.* (from *muck.*) Nasty; filthy.

MUCOR. Mould. In botany, a genus of the class cryptogamia, order fungi. Fungus fugacious; heads at first diaphonous, becoming opake, on simple, or branched stems. The species differ according to the arrangement of different botanists. If those which we have noticed as belonging to the genus fuligo be added, the number is swelled to fifteen or sixteen; if the whole be separated into two or three different genera, those properly belonging to the genus mucor are reduced to ten. It comprises, 1. M mucedo, or common grey mould, growing so readily on bread, fruits, plants, and other substances in a putrid state. This species rises in clusters; the stalks a quarter of an inch high, pellucid, hollow, and cylindrical; supporting each a single globular head, at first transparent, afterwards dark-grey; which bursts with elastic force, and ejects small round seeds, discoverable by the microscope.

2. M. sphærocephalus: grey, round-headed mucor, growing upon rotten wood, and sometimes upon decayed plants and mosses. The stalks of this are generally black, about a line in height, bearing each at the top a sphærical ball, about the size of a pin's head; its coat or rind is covered with a grey powder, and contains internally a black or fungous spongy down. The coat bursts with a ragged irregular margin.

3. M. lichenoides, or little black, pin-headed mucor: growing in groups near each other, in chasms of the bark of old trees, and upon old park-pales. The stalks are black, about two lines in height, bearing each a single head, sometimes a double or treble one, of the size of mustard or poppy-seeds, of a roundish figure at first, but when burst, often flatted or truncated, and of a black colour. The internal powdery down is black with a tinge of green.

4. M. erisiphe. 5. M. granulosus. Mildew. The first, sessile, white, with brown heads. The second sessile and blackish. The former is the albigo of Wildenow: yet the common corn-mildew is rather the mucor granulosus, or probably a species of œcidium, the rubigo of Wildenow: whose albigo is blight or white-mildew; his rubigo, rust or red-mildew; and his ustilago, smut, or black-mildew. See Ustilago and Husbandry.

MU'COUS. *a.* (*mucosus*, Latin.) Slimy; viscous (*Brown*).

Mucous glands. Glandulæ mucosæ. Muciparous glands. Glands that secrete mucus, such as the glands of the Schneiderian membrane of the nose, the glands of the fauces, œsophagus, stomach, intestines, bladder, urethra, &c.

MU'COUSNESS. *s.* Slime; viscosity.

MUCRONATE. (from μακρος, *long*, according to some; from μικρος, *small*, according to others.) In botany, dagger-pointed. Hence

Mucronate leaf. A dagger-pointed leaf. Terminating in a sharp point like a dagger; as in bromelia ananas. Applied also to the calyx. The diminutive mucronulate is sometimes used.

MU'CULENT. *a.* (from *mucus*, Latin.) Viscous; slimy.

MUCUS. Animal mucilage. In animal chemistry, a fluid secreted by certain glands, and serving to lubricate many of the internal cavities of the body. It has been very generally confounded with other animal secretions; but is distinguished by the following characters, which were deduced by Dr. Bostock from saliva and the mucus liquid of an oyster evaporated to dryness.

It has much the appearance of gum-arabic, excepting that in general it is rather more opake: like gum-arabic it has little taste, dissolves readily in water, and forms an adhesive solution. It does not dissolve in alkohol or in ether. It does not coagulate when heated; nor when concentrated by evaporation does its solution assume the form of a jelly. It is not precipitated by the oxymuriat of mercury, nor by the infusion of galls. The acetat of lead occasions a copious white precipitate when dropt into solutions containing mucus; the superacetat produces a much less striking effect. Nitrat of silver likewise occasions precipitate in solutions containing mucus.

Mucus till of late was supposed to be a gelatinous principle; but Mr. Brande, in a series of valuable experiments inserted in the Philosophical Transactions for 1809, part ii. p. 376, has very sufficiently proved it to be chiefly albuminous. These experiments have also ascertained that albumen is rendered fluid by the possession of its alkaline matter; and that whenever this alkali is parted with, it immediately coagulates. Hence it is completely coagulated by the Voltaic battery, the alkali being sent off to the negative pole, while whatever acid is contained travels to the positive. It is coagulated by alkohol, and by acid, and by heat; all which may be referred to the same principle. The use of this substance is to lubricate and defend the parts upon which it is secreted, as the nose, œsophagus, stomach, intestines, urethra, vagina, &c.

Mucus (Vegetable). See Gum and Mucilage.

MUD. *s.* (*modder*, Dutch.) The slime and uliginous matter at the bottom of still water (*Addison*).

To Mud. *v. a.* (from the noun.) 1. To bury in the slime or mud (*Shakspeare*). 2. To make turbid; to pollute with dirt; to dash with dirt (*Glanville*).

Mud-fish, in ichthyology. See Cobitis.

Mud-iguana. See Muræna.

MU'DDILY. *ad.* (from *muddy*). Turbidly; with foul mixture (*Dryden*).

MU'DDINESS. *s.* (from *muddy.*) Turbidness; foulness caused by mud or sediment (*Addison*).

To MU'DDLE. *v. a.* (from *mud.*) 1. To make turbid; to foul (*Prior*). 2. To make half drunk; to cloud or stupify (*Arbuthnot*).

MU'DDY. *a.* (from *mud.*) 1. Turbid; foul with mud (*Shakspeare*). 2. Impure; dark; gross (*Shakspeare.*) 3. Soiled with mud (*Dryden*). 4. Dark; not bright (*Swift*). 5. Cloudy in mind; dull (*Shakspeare*).

To Mu'ddy. *v. a.* (from *mud.*) To make muddy; to cloud; to disturb (*Grew*).

MU'DSUCKER. *s.* (*mud* and *suck*). A seafowl (*Derham*).

MUDWA'LL. *s.* (*mud* and *wall.*) 1. A wall built without mortar, by throwing up mud and suffering it to dry (*South*). 2. (*apiaster.*) A bird (*Ainsworth*).

MUDWA'LLED. *s.* (*mud* and *wall.*) Having a mudwall (*Prior*).

To MUE. *v. a.* (*muer*, French.) To moult; to change feathers

MUFF. *s.* (*muff*, Swedish.) A soft cover for the hands in winter (*Cleaveland*).

To MU'FFLE. *v. a.* (from *moufle*, French.) 1. To cover from the weather (*Dryden*). 2. To blindfold (*Shakspeare*). 3. To conceal; to involve (*Sandys*).

To MU'FFLE. *v. n.* (*maffelen*, *moffelen*, Dutch.) To speak inwardly; to speak without clear and distinct articulation (*Holder*).

MUFFLE, in metallurgy, an arched cover, resisting the strongest fire, and made to be placed over coppels and tests in the operations of assaying, to preserve them from the falling of coals and ashes into them; though, at the same time, of such a form, as is no hindrance to the action of the air and fire on the metal, nor to the inspection of the assayer. The muffles may be made of any form, providing they have these conditions; but those used with coppels are commonly made semi-cylindrical; or when greater vessels are employed, in form of a hollow hemisphere. The muffle must have holes, that the assayer may look in; and the fore part of it must be always quite open, that the air may act better in conjunction with the fire, and be incessantly renewed; the apertures in the muffle serve also for the regimen of the fire, for the cold air rushing into the large opening before, cools the bodies in the vessel; but if some coals are put in it, and its aperture before be then shut, with a door fitted to it, the fire will be increased to the highest degree, much more quickly than it can be by the breathing holes of the furnace. See ASSAYING.

MU'FFLER. *s.* (from *muffle*.) 1. A cover for the face (*Arbuthnot*). 2. A part of a woman's dress by which the face was covered (*Shakspeare*).

MUFTI, or MUPHTI, the chief of the ecclesiastical order, or primate, of the mussulman religion. The authority of the mufti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment.

The election of the mufti is solely in the grand signior, who presents him with a vest of rich sables, &c. If he is convicted of treason, or any great crime, he is put into a mortar, kept for that purpose in the Seven Towers at Constantinople, and pounded to death.

MUG. *s.* A cup or vessel to drink out of.

MUGGLETONIANS, a religious sect, which arose in England, about the year 1657; so denominated from their leader Lodowick Muggleton, a journeyman taylor, who, with his associate Reeves, set up for great prophets, pretending, as it is said, to have an absolute power of saving and damning whom they pleased; and giving out that they were the two last witnesses of God that should appear before the end of the world.

MUGIL. Mullet. In zoology, a genus of the class pisces, order abdominalia. Lips membranaceous, the lower ones carinate inwards; toothless; above the angle of the mouth a hard callus; gill-membrane with seven curved rays; the covers smooth, rounded; body whitish. Five species, as follow:

1. M. cephalus. Common mullet. First dorsal fin five-rayed. Inhabits European seas, and enters rivers: back dusky, varied with blue and green; sides silvery, with broad, dusky, parallel lines, reaching from the head to the tail; belly silvery; scales arranged in parallel rows: two dorsal fins, the first near the middle of the back; tail deeply forked.

The residence of the mullet is the sandy shoals and bays, into which there is an inlet of fresh water: in such situations, they are found all round the shores of Great Britain, where they leave the sand all marked with round holes, the traces of their digging, for they keep constantly rooting like hogs among the mud. When surrounded by a net, the whole shoal frequently escapes by leaping over it; one attempting this mode of escape, and succeeding, is immediately followed by all the rest.

Mullets are also plentiful in the Mediterranean, and along the southern coasts of France. In a certain lake near Martegues, in the south of France, there are vast shoals which enter during spring, the season of copulation among these fishes; after impregnation they return to the sea, but are intercepted by weres of reeds.

Of the milts and roes of the mullet the botargo of the Italians is composed. The materials are taken out entire, and for a few hours covered up with salt; afterwards they are pressed between two boards, dried in the sun for about a fortnight, and are then fit for use. This composition is said to brace a weak stomach, and to give an exquisite relish to wine.

The food of the mullet is mud, or sea-weeds; it never attempts to devour any fish. The flesh is palatable, though at present not a fashionable dish: its flavour greatly depends on the ground where it is fed; if among mud, it constantly tastes and smells of that kind of food.

2. M. albula. First dorsal fin four-rayed. Inhabits America; very much resembles the last.

3. M. crenilabis. Crenated mullet. First dorsal fin with four flexible rays; rays of the second unarmed; lips crenate, the lower bicarinate. Three other varieties, from variety in the size, ciliation, or carination. Inhabits the Red sea; a foot long; scales broad, with a longitudinal brown keel in the middle.

4. M. Chilensis. Dorsal fin single; tail simple. Inhabits the sea round Chili, and the rivers which empty themselves into it: about a foot long: in shape of scales resembles M. cephalus.

5. M. chanos. Dorsal fin single; tail with two wings on each side. Inhabits the Red sea: a yard long; body oblong, silvery, with soft cirrhi, but without teeth; scales broad, rounded, finely striate. A second variety, more than as large again. See Nat. Hist. Pl. CLVI.

MUGWORT. See ARTEMISIA.

MUHLBERG, a town of Upper Saxony, in the margravate of Meissen, with a castle, situate on the Elbe, 19 miles N.W. of Meissen, and 32 N.W. of Dresden. Lon. 13. 9 E. Lat. 51. 25.

MUHLENBERGIA, in botany, a genus of the class triandria, or digynia. Calyx one-valved, minute, lateral; corol two-valved. One species only, a North American grass, with prostrate culm, and slender panicle at the end of the alternate branches.

MUHLROSE, a town of Upper Saxony, in the Middle Marche of Brandenburg, situate on a navigable canal, which forms a communication by water from Hamburg to Breslaw, nine miles S.W. of Frankfort on the Oder.

MUID, a large measure in use among the French, for things dry. The muid is no real vessel used as a measure, but an estimation of several other measures; as the septier, mine, minot, bushel, &c.

Muid is also one of the nine casks, or regular vessels used in France to put wine and other liquors in. The muid of wine is divided into two demi-muids, four quarter-muids, and eight half-quarter muids, containing 36 septiers.

MUIRKIRK, a town in Ayrshire, seated on the river Ayr, and noted for a considerabe iron work.

MULATTO, a name given in the Indies to those who are begotten by a negro man on an Indian woman, or by an Indian man on a negro woman.

MULBERRY, in botany. See Morus.

Mulberry blite. See Blitum.

MULCH, a term in gardening to denote such strawy dung as is somewhat moist but not rotten. It is found useful for protecting the roots of new-planted, choice trees or shrubs from severe frost in winter, and from being dried by the fierce sun or drying winds in spring and summer before they are well rooted.

MULCT. *s.* (*mulcta*, Latin.) A fine; a penalty: used commonly of pecuniary penalty.

To **Mulct.** *v. a.* (*mulcto*, Latin.) To punish with fine or forfeiture (*Bacon*).

MULCIBER, a sirname of Vulcan.

MULE. (*mula*, Latin.) A hybrid or mixt breed from copulation of two distinct species of the same genus; commonly of a male ass with a mare, or of a stallion with a female ass, in which last case the foal or filly is called a hinny.

Among animals there can be no doubt that the power of procreation in the hybrid race is very slender and limited, though the cause of this curious fact has never been ascertained. It has generally been affirmed that the proper mule (the issue of the horse and ass) never propagates: and Mr. John Hunter endeavoured hence to lay down a general law to determine between the species and varieties of animal genera: and published a valuable paper in proof that the wolf, jackal, and dog are only varieties of the same species, merely from facts in his possession, that the young produced by copulation between any of these animals are capable of procreating.

It is not true, however, as an universal proposition, that hybrid animals, or those issuing from the connexion of different species, never propagate. Even mules and hinnies have been occasionally found to propagate in warm climates, and other hybrids in climates of all kinds. Mr. John Hunter threw out a hint, that such cases might probably be the result of a monstrosity in the sexual organs of one of the parents, by which though a hybrid in other respects, it retained in these organs the make and powers of the perfect species. But the hint is supported by no fact whatever, and can only be contemplated as an ingenious loop-hole to escape from an insuperable difficulty.

The translator of Buffon's works has given a remarkable and well authenticated instance of the prolific powers of a she-mule in the north of Scotland. Having heard that a mule, belonging to Mr. David Tullo, farmer in Auchtertyre, in the county of Forfar, had some years ago brought forth a foal, he transmitted a few queries to be put to Mr. Tullo; and requested that his answers might be legally attested before a magistrate. This request was cheerfully complied with; and the following is an exact copy of the queries, answers, and attestations.

Interrogatories to be put to Mr. Tullo, tenant in Auchtertyre, parish of Newtyle, and county of Forfar, with his answers thereto.

1mo, Had you ever a she-mule? At what period? Is it true that the mule had a foal? At what time was she covered? and when did she foal?—Answered by Mr. Tullo: That he bought a she-mule about 20 years ago: That she was constantly in season for a horse: That, some years thereafter, he gave her a horse; and that she thereafter gave him a foal, about the 10th of June. The mule's price was 4l. 5s. sterling.

2do, What was the colour of the foal? Was there any thing particular in its figure?—Answer: The foal was exactly the colour of its mother, inclined to black, with a very large head, big ears, and small tail; and the declarant thinks, had its head been weighed when foaled, it would have weighed nearly as much as its body.

3tio, How long was the animal allowed to live?—Answer: The next day after the mule foaled, it was sent, with its mother, to the Loch of Lundie, in order to let the foal die, as the declarant could not want the mule's work, and the mother seemed not fond of the foal: That it was accordingly left, and next day came to Auchtertyre, about two miles distance, over a hill, with the cattle of Auchtertyre, that had been grazing near that place, and was drowned in a ditch the day following.

4to, Was its skin preserved, or the head, or any other bones of the skeleton? Could any part thereof be still found?—Answer: Neither the skin nor any part of the skeleton was preserved, nor can be now had; though the declarant has often regretted the not preserving the foal, as its mother always performed any work that a horse of 15l. value could do.

5to, Is the mother still alive? What is her age?—Answer: The mother died about eight years ago, of an epidemic cold that was raging among the horses in this country: the mule had little or no milk after foaling, and the foal got some cow's milk: and this is all that he remembers of the matter. David Tullo.

Auchtertyre, 4th Feb. 1780.—We James Small, tenant in Burmouth, and Robert Ramsay, tenant in Newtyle, hereby certify that we have often seen the mule above described; and we know that she had a foal, as is narrated by David Tullo.

James Small. Rob. Ramsay.

Ballantyne-house, 4th Feb. 1780.—The within interrogatories were put to David Tullo, tenant in Auchtertyre, anent the mule he had, and the foal she produced: to which he gave the answers subjoined to each query, and signed them; as did James Small and Robert Ramsay, attesting the truth thereof, in presence of George Watson, J. P.

The original attestation is in the possession of the translator's family, he having before he died transmitted notorial or authenticated copies of it to the count de Buffon, and to Thomas Pennant, esq. of Downing, in Flintshire.

Koelreuter, in like manner, among vegetables found the hybrids of various species to be sterile; and especially those formed by the sexual connexion of different species of tobacco; as for example of the female nicotiana rustica with the male nicotiana paniculata. But we are also in possession of various instances of hybrid plants which retain the original hybrid form, and continue to propagate themselves. We shall quote a few from Wildenow.

Sorbus hybrida. The mother was sorbus aucuparia; the father cratægus aria.

Pyrus hybrida. The mother was pyrus arbutifolia; the father sorbus ancaperia.

Rhammus hybridus. The mother was rhammus alpinus; the father rhammus alaternus.

What mixtures do not the species of pelargenium produce in our gardens? almost all the plants of the Linnéan classes xxi. xxii. xxiii. generate prolific hybrids. When M. Wildenow in conclusion offers a general query, whether from the observations already made upon the hybrids both of the animal and vegetable world, it may not be laid down as a rule, admitting some exceptions, that all hybyrids are productive, but that some only requipe a warm climate to unfold the male semen? "I do not," continues he, "attempt to establish this rule as quite certain: and should be happy if philosophers would consider the subject more accurately, and more minutely attend to the hybrids of different climates in order to settle the question."

Mules properly so called (the offspring of the horse and the ass) are chiefly used in countries where there are rocky and stony ways, as about the Alps and Pyrenees, &c. Great numbers of them are kept in these places: they are usually black, and are strong, well-limbed, and large, being mostly bred out of the fine Spanish mares. The mules are sometimes fifteen or sixteen hands high, and the best of them are worth forty or fifty pounds a-piece. No creatures are so proper for large burdens, and none so sure-footed. They are much stronger for draught than our horses, and are often as thick-set as our dray-horses, and will travel several months together, with six or eight hundred weight upon their backs. It is a wonder that these creatures are not more propagated in England, as they are so much hardier and stronger than horses, and are less subject to diseases, and will live and work to twice the age of a horse. Those that are bred in cold countries are more hardy and fit for labour than those bred in hot; and those which are light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough; though these do it much less than the short-made ones.

They take so much after the mares they are bred from, that they may be procured of any kind, light or strong, as the owner pleases. The general complaint we make against them, is that they kick, and are stubborn; but this is only owing to our neglect in the breeding them, for they are as gentle as our horses, in countries where they are bred with more care.

Mules are of two kinds; the one between the horse and the she-ass, the other between the he-ass and the mare. The first sort are the least valuable. They are commonly very dull, and take after the ass, and are not large; the other breed is therefore what is propagated chiefly in all countries where mules are used. The largest and finest he-ass must be procured for this breed; and in Spain, where mules are greatly esteemed, they will give fifty or sixty pounds for a fine he-ass, only to be kept as a stallion. They breed with this creature out of the finest and largest mares they have, giving the ass an advantage of height of ground, and putting the mare into a narrow pit, railed on each side. If the ass designed to be bred on is suckled by a mare, or the mare suckled with an ass, it makes them much more familiar than they would otherwise be; and this may always be done by taking away the colt that belongs to the dam, and putting the other in its place, keeping them in the dark ten days or a fortnight.

Mule plant. See Hybrid.

Mule pink, in botany. See Dianthus.

Mules in the legs of a horse. See Kibed heels.

MULETE'ER. *s.* (*muletier*, Fr.) Mule-driver; horse-boy (*Shakspeare*).

MULHAUSEN, an imperial and hanseatic town of Germany, in Thuringia, under the protection of the elector of Saxony. It is seated in a fertile country, on the Unstrutht, 15 miles N.E. of Eisenach, and 45 E. by S. of Cassel. Lon. 10. 49 E. Lat. 51. 13 N.

Mulhausen, a town of Alsace, which, though intirely inclosed within the dominions of France, is not only in alliance with the Helvetic confederacy, but is considered as a part of it, and entitled to all its privileges. The walls of the town inclose a circumference of not more than two miles; and its whole territory is confined within a precinct of eight miles. The town contains 6000 inhabitants, who are protestants; and there are 2000 subjects in its adjacent villages. It owes its present flourishing state to its manufactures, which are chiefly of printed linens and cottons. The government is aristo-democratical. The supreme power resides in the great and little council, consisting together of 78 persons, and drawn from the burghers, whose number amounts to 700, distributed into six tribes. Mulhausen is 15 miles N.W. of Basil. Lon. 7. 24 E. Lat. 47. 48 N.

MULHEIM, a town of Germany, in the electorate of Cologne, seated near the Rhine, three miles from Cologne. Here the few protestants in Colonge are obliged to go to perform divine service.

MULHEIM, a town of Westphalia, in the duchy of Berg, situate on the Rhur, 14 miles N. of Dusseldorf. Lon. 6. 51 E. Lat. 51. 26 N.

MULIE'BRITY. *s.* (*muliebris*, Latin.) Womanhood; the correlative to virility.

To MULL. *v. a.* (*mollitus*, Latin.) 1. To soften and dispirit, as wine is when burnt and sweetened (*Shakspeare*). 2. To heat any liquor, and sweeten and spice it (*Gay*).

MULL, one of the Western Islands of Scotland, 25 miles in length, and, in some places, of equal breadth. There are many good natural harbours; but there is only one village, called Tobermorey. The soil is, for the most part, rocky and barren; but the hills abound with springs, and are covered with cattle: these, with the fishery, and a considerable quantity of kelp, are the only articles of commerce. The ruins of several ancient castles are seen on this island.

MULL OF CANTYRE. See CANTYRE.

MULL OF GALLOWAY, a rocky promontory, the most southerly point of Scotland, in the county of Wigton.

MULLAT of alumina, in mineralogy. See MELLITES.

MULLEIN, in botany. See VERBASCUM.

MULLER (John), commonly called REGIOMONTANUS, from Mons Regius, or Koningsberg, a town in Franconia, where he was born in 1436, and became the greatest astronomer and mathematician of his time. He was indeed a very prodigy for genius and learning. Having first acquired grammatical learning in his own country, he was admitted, while yet a boy, into the academy at Leipsic, where he formed a strong attachment to the mathematical sciences, arithmetic, geometry, astronomy, &c. But not finding proper assistance in these studies at this place, he removed, at only 15 years of age, to Vienna, to study under the famous Purbach, the professor there, who read lectures in those sciences with the highest reputation. A strong and affectionate friendship soon took place between these two, and our author made such rapid improvement in the sciences, that he was able to be assisting to his master, and to become his companion in all his labours. In this manner they spent about ten years together; elucidating obscurities, observing the motions of the heavenly bodies, and comparing and correcting the tables of them; particularly those of Mars, which they found to disagree with the motions, sometimes as much as two degrees.

About this time there arrived at Vienna the cardinal Bessarion, who came to negociate some affairs for the pope; and, being a lover of astronomy, soon formed an acquaintance with Purbach and Regiomontanus. He had begun to form a Latin Version of Ptolemy's Almagest, or an Epitome of it; but not having time to go on with it himself, he requested Purbach to complete the work, and for that purpose to return with him into Italy, to make himself master of the Greek tongue, which he was as yet unacquainted with. To these proposals Purbach only assented, on condition that Regiomontanus would accompany him, and share in all the labours. They first, however, by means of an Arabic Version of Ptolemy, made some progress in the work; but this was soon interrupted by the death of Purbach, which happened in 1461, in the 39th year of his age. The whole task then devolved upon Regiomontanus, who finished the work, at the request of Purbach, made to him when on his death-bed. This work our author afterwards revised and perfected at Rome, when he had learned the Greek language, and consulted the commentator Theon, &c.

Regiomontanus accompanied the cardinal Bessarion in his return to Rome, being then near 30 years of age. Here he applied himself diligently to the study of the Greek language; not neglecting however to make astronomical observations and compose various works in that science; as his Dialogue against the Theories of Cremonensis. The cardinal going to Greece soon after, Regiomontanus went to Ferrara, where he continued the study of the Greek language under Theodore Gaza; who explained to him the text of Ptolomy, with the commentaries of Theon; till at length he became so perfect in it, that he could compose verses, and read it like a critic. In 1463 he went to Padua, where he became a member of the university; and, at the request of the students, explained Alfraganus, an Arabian philosopher. In 1464 he removed to Venice, to meet and attend his patron Bessarion. Here he wrote, with great accuracy, his Treatise of Triangles, and a Refutation of the Quadrature of the Circle, which Cardinal Cusan pretended he had demonstrated. The same year he returned with Bessarion to Rome; where he made some stay, to procure the most curious books: those he could not purchase he took the pains to transcribe, for he wrote with great facility and elegance; and others he got copied at a great expence. For as he was certain that none of these books could be had in Germany, he thought on his return thither he would at his leisure translate and publish some of the best of them. During this time too he had a fierce contest with George Trabezonde, whom he had greatly offended by animadverting on some passages in his translation of Theon's Commentary.

Being now weary of rambling about, and having procured a great number of manuscripts, which was one great object of his travels, he returned to Vienna, and performed for some time the offices of his professorship, by reading lectures, &c. After being a while thus employed, he went to Buda, on the invitation of Matthias king of Hungary, who was a great lover of letters and the sciences, and had founded a rich and noble library there: for he had bought up all the Greek books that could be found on the sacking of Constantinople; also those that were brought from Athens, or wherever else they could be met with through the whole Turkish dominions, collecting them all together into a library at Buda. But a war breaking out in this country, he looked out for some other place to settle in, where he might pursue his studies, and for this purpose he retired to Noremberg, where he set up a printing-house, formed a nomenclature of the books he meant to publish, and cultivated an intimacy with the celebrated Bernard Walther, who cheerfully co-operated with him in his literary and scientific undertakings. Here he pubished the New Theories of his master Purbach, the Astronomicon of Manilius, his own New Calendar, Ephemerides, &c. He likewise prepared a new version of Ptolomy's Cosmography.

In 1474, pope Sixtus the 4th conceived a design of reforming the calendar; and sent for Regiomontanus to Rome, as the properest and ablest person to accomplish his purpose. Regiomontanus was very unwilling to interrupt the studies, and printing of books, he was engaged in at Noremberg; but receiving great promises from the pope, who also for the present named him bishop of Ratisbon, he at length consented to go. He arrived at Rome in 1475, but died there the year after, at only 40 years of age; not without a suspicion of being poisoned by the sons of George Trabezonde, in revenge for the death of their father, which was said to have been caused by the grief he felt on account of the criticisms made by Regiomontanus on his translation of Ptolomy's Almagest.

Purbach first of any reduced the trigonometrical tables of sines, from the old sexagesimal division of the radius, to the decimal scale. He supposed the radius to be divided into 600000 equal parts, and computed the sines of the arcs to every ten minutes, in such equal parts of the radius, by the decimal notation. This project of Purbach was perfected by Regiomontanus; who not only extended the sines to every minute, the radius being 600000, as designed by Purbach, but afterwards, disliking that scheme, as evidently imperfect, he computed them likewise to the radius 1000000, for every minute of the quadrant. Regiomontanus also introduced the tangents into trigonometry, the canon of which he called fæcundus, because of the many great advantages arising from them. Beside these things, he enriched trigonometry with many theorems and precepts. Indeed, excepting for the use of logarithms, the trigonometry of Regiomontanus is but little inferior to that of our own time. His Treatise, on both Plane and Spherical Trigonometry, is in 5 books; it was written about the year 1464, and printed in folio at Noremberg in 1533. In the 5th book are various problems concerning rectilinear triangles, some of which are resolved by means of algebra: a proof that this science was not wholly unknown in Europe before the treatise of Lucas de Burgo.

Regiomontanus was author of some other works beside those before mentioned. Peter Ramus, in the account he gives of the admirable works attempted and performed by Regiomontanus, tells us, that in his workshop at Noremberg there was an automaton in perpetual motion: that he made an artificial fly, which taking its flight from his hand, would fly round the room, and at last, as if weary, would return to his master's hand: that he fabricated an eagle, which, on the emperor's approach to the city, he sent out, high in the air, a great way to meet him, and that it kept him company to the gates of the city. Let us no more wonder, adds Ramus, at the dove of Archytas, since Noremberg can shew a fly, and an eagle, armed with geometrical wings. Nor are those famous artificers, who were formerly in Greece and Egypt, any longer of such account, since Noremberg can boast of her Regiomontanuses. For Wernerus first, and then the Schoneri, father and son, afterwards, revived the spirit of Regiomontanus.—(*Hutton's Dict.*)

Muller (John), a noted engraver, who flourished about the year 1600, and had been bred under Henry Goltzius, whose style he closely imitated. The facility with which he handled the graver (for he worked with that instrument only) cannot be sufficiently expressed; his works must be seen, to convey a proper idea of it to the mind. His engravings are valuable, as productions of a very extraordinary nature; exclusive of which they have a prodigious share of merit. Among his most estimable performances, may be mentioned, 1. The hand-writing on the wall, a middling-sized plate lengthwise, from his own composition. 2. The adoration of the wise men, the same, from the same. Fine impressions of both these prints are very rare. 3. The resurrection of Lazarus, a large plate lengthwise, from Abraham Bloemart. He engraved also several much esteemed portraits.

Muller, or **Mullar**, denotes a stone flat and even at the bottom, but round at top, used for grinding of matters on a marble. The apothecaries use mullers to prepare some of their testaceous powders, and painters for their colours, either dry or in oil. Muller is also an instrument used by the glass-grinders; being a piece of wood, to one end whereof is cemented the glass to be ground. It is ordinarily about six inches long, turned round.

Muller's glass, in mineralogy. See Olivinus.

MULLERA, in botany, a genus of the class diadelphia, order decandria. Calyx four-toothed; loment moniliform, with fleshy

Mullus Trifasciatus.
Trifaciate Surmullet

London, Published by Sherwood & Co. Paternoster Row, March 1st 1822.

one-seeded globules cohering by a thread. One species only; a Surinam tree with ferruginous branches, and nodding flowers; five leaflets, ovate-oblong, and silky underneath.

MULLERAS, a town of Germany, in the middle marche of Brandenburg, seated on a canal cut between the Spree and Oder, 40 miles S.E. of Berlin. Lon. 14. 31 E. Lat. 52. 14 N.

MULLET, in ichthyology. See MUGIL.

MULLIGRUBS, a low word used sometimes to denote gripes, at others, sullenness.

MULLINGAR, the county town of West Meath, in Ireland. It holds a great wool-mart, is a place of good trade, and sends two members to parliament. It is seated on the Foyle, 38 miles W. of Dublin. Lon. 7. 50 W. Lat. 53. 30 N.

MULLUS. Surmullet. In zoology, a genus of the class pisces, order thoracica. Head compressed, sloping, scaly: eyes oblong, approximate, vertical, furnished with a nictitant membrane; nostrils double, minute; jaws and palate armed with small teeth; tongue short, narrow, smooth, fixed; gill membrane three-rayed; the covers of three pieces, very finely striate; body round, long, red, coated with large scales, easily dropping off. Six species, as follow.

1. M. barbutus. Red surmullet. Lower jaw with two cirrhi; body red. Inhabits European, Mediterranean, and Pacific seas; body, when deprived of its scales, red. Nothing can be more beautiful than the colours of this fish when it is dying, and nothing more delicious than its flesh. The ancient Romans held it in such vast repute that prodigious sums were given for them; they were often bought at their weight in pure silver. It was in the purchase of this fish, indeed, above all others, that the wealthy senators shewed their extravagance and sensuality. Juvenal and Pliny afford ample testimony of the luxury of their age, which, happily for mankind, has never been equalled in any other period of human society. An instance of sixty-four pounds sterling being paid for a fish of three pounds weight, is recorded by Pliny.

But the manner of dressing and eating these fishes still more than the extravagance of the price, shewed the epicurism of the ancient entertainments. The mullet was not reckoned worth a farthing if he did not die in the hand of your guest. There was water kept in the eating room into which the living animal was put, and from thence conveyed immediately to the stew, where it was dressed, which was also in the same apartment, and under the table; from thence the fish was placed upon it. It was customary to put the mullets into glass vases, that the company might be entertained with the various changes of their rich colours as they lay expiring. It was Apicius, that prince of gluttons, that first hit upon the ingenious invention of suffocating them in the exquisite Carthaginian pickle, and afterwards procuring a rich sauce from their livers.

2. M. surmeletus. Striped surmullet. Cirrhi two; body with four longitudinal yellow lines; fins yellow, the rays chiefly red; head large; eyes round; pupil blue, surrounded with a red ring, iris silvery. Inhabits European, American, and Mediterranean seas: from a span to a foot long; scales silvery, streaked with tawny; feeds on other fishes, testaceous animals, crabs and carcases; is gregarious, and approaches the shore in the spring for the purpose of spawning: its flesh equally delicious with the last.

3. M. Japanicus. Yellow, without stripes; tail forked; cirrhi two: jaws toothless. Inhabits Japan; about six inches long: is hardly to be distinguished from M. barbutus.

4. M. auristamma. Cirrhi two, white; on each side a tawny stripe; tail yellow; teeth small, numerous; tail with a small black spot: scales membranaceous at the edge. Inhabits the Red sea.

5. M. vittatus. Cirrhi two; body with two brown and three yellow stripes on each side; tail obliquely brown: scales finely toothed, with obsolete elevated rivulets. Inhabits the Red sea.

6. M. imberbis. Lower jaw without cirrhi. Inhabits the coast of Malta. See Nat. Hist. Plate CLVI.

MULSE. *s.* (*mulsum*, Latin.) Wine boiled and mingled with honey.

MULTA'NGULAR. *a.* (*multus* and *angulus*, Latin.) Many cornered; having many corners; polygonal.

MULTA'NGULARLY. *ad.* Polygonally; with many corners (*Grew*).

MULTA'NGULARNESS. *s.* The state of being polygonal, or having many corners.

MULTICA'PSULAR *a.* (*multa* and *capsula*, Latin.) Divided into many partitions or cells.

MULTICAPSULAR PERICARP. In botany, a fruit of many capsules. Having several pericarps succeeding to a flower. As in caltha, trollius, helleborus.

MULTICA'VOUS. *a.* (*multus* and *cavus*, Lat.) Full of holes.

MULTIDENTATE COROL. In botany, a many-toothed corol. Cujus limbus aut petala margine dissecta sunt. Having the border (in a monopetalous corol) or the petals (if it be polypetalous) cut about the edge.

MULTIFA'RIOUS. *a.* (*multifarius*, Lat.) Having great multiplicity; having different respects (*More. Evelyn*).

MULTIFA'RIOUSLY. *ad.* With multiplicity; with great variety of modes (*Bentley*).

MULTIFA'RIOUSNESS. *s.* (from *multifarious.*) Multiplied diversity (*Norris*).

MULTI'FIDOUS. *a.* (*multifidus*, Lat.) Having many partitions; cleft into many branches (*Brown*).

MULTIFIDUS SPINÆ. (*multifidus*, from *multus*, many, and *findo*, to divide.) In anatomy, transverso spinalis lumborum, veterib sacer. Semi-spinalis internus, sive transverso-spinalis dorsi. Semi-spinalis, sive transverso-spinalis colli, pars interna of Winslow. Transversalis lumborum vulgo sacer. Transversalis dorsi. Transversalis colli of Douglas. The generality of anatomical writers have unnecessarily multiplied the muscles of the spine, and hence their descriptions of these parts are confused, and difficult to be understood. Under the name of multifidus spinæ, Albinus has therefore very properly included those portions of muscular flesh, intermixed with tendinous fibres, which lie close to the posterior part of the spine, and which Douglas and Winslow have described as three distinct muscles, under the names of transversales, or transverso-spinales, of the loins, back, and neck. The multifidus spinæ arises tendinous and fleshy from the upper convex surface of the os sacrum, from the posterior adjoining part of the ilium, from the oblique and transverse processes of all the lumbar vertebræ, from the transverse processes of all the dorsal vertebræ, and from those of the cervical vertebræ, excepting the three first. From all these origins the fibres of the muscle run in an oblique direction, and are inserted, by distinct tendons, into the spinous processes of all the vertebræ of the loins and back, and likewise into those of the six inferior vertebræ of the neck. When this muscle acts singly, it extends the back obliquely, or moves it to one side; when both muscles act, they extend the vertebræ backwards.

MULTIFLOROUS. In botany, many-flowered. Common to several flowers. A many-flowered stem; as in several species of iris, &c. A many-flowered scape; as in primula officinalis, auricula, polyanthus, &c. Calyx; as in scabiosa, and the class syngenesia; when the component flowers are called florets or floscules. A many-flowered peduncle; as in browallia elata.

MU′LTIFORM. *a.* (*multiformis*, Lat.) Having various shapes or appearances (*Milton*).

MULTIFO′RMITY. *s.* (*multiformis*, Lat.) Diversity of shapes or appearances subsisting in the same thing.

MULTILA′TERAL. *a.* (*multus* and *lateralis*, Latin.) Having many sides.

MULTILO′CULAR PERICARP. In botany, a many-celled pericarp. Divided internally into several cells; as in nymphæa.

MULTI′LOQUOUS. *a.* (*multiloquus*, Lat.) Very talkative.

MULTINOMIAL, or Multinominal roots, in mathematics, are such as are composed of many names, parts, or members; as, $a+b+c+d$, &c.

For the method of raising an infinite multinominal to any given power, or of extracting any given root out of such a power, see a method of M. de Moivre, in Phil. Trans. No. 230.

MULTIPA′ROUS. *a.* (*multiparus*, Lat.) Bringing many at a birth (*Brown*).

MULTI′PARTITE COROL. In botany, a many-parted corol. Multipartite leaf. A many-parted leaf. Divided into several parts almost to the bottom.

MU′LTIPEDE. *s.* (*multipeda*, Lat.) An insect with many feet.

MULTIPLE, Multiplex, in arithmetic, a number which comprehends some other several times.

Thus 6 is a multiple of 2, or, which is the same, 2 is a quota part of 6; 2 being contained in 6 three times. And thus 12 is a multiple of 6, 4, 3; and comprehends the first twice, the second thrice, the third four times, &c.

Multiple ratio, or proportion, is that which is between multiple numbers.

If the lesser term of a ratio be an aliquot part of the greater, the ratio of the greater to the less is called multiple; and that of the less to the greater sub-multiple.

A sub-multiple number is that contained in the multiple. Thus the numbers 1, 2, and 3, are sub-multiples of 6 and 9.

Duple, triple, &c. ratios; as also sub-duples, sub-triples, &c. are so many species of multiple, and sub-multiple ratios.

Multiple superparticular proportion, is when one number or quantity contains another more than once, and a certain aliquot part; as $3\frac{1}{3}$ to 1.

Multiple superpartient proportion, is when one number or quantity contains anothers diverse times, and some parts besides; as $4\frac{5}{6}$ to 1.

MULTIPLEX COROL. Many-fold, or having petals lying over each other in two or more folds or rows.

MULTIPLI′ABLE. *a.* (*multipliable*, Fr. from *multiply*.) Capable of being multiplied.

MULTIPLI′ABLENESS. *s.* (from *multipliable*.) Capacity of being multiplied.

MULTIPLICA′BLE. *a.* (from *multiplico*, Latin.) Capable of being arithmetically multiplied.

MULTIPLICA′ND. *s.* (*multiplicandus*, Lat.) The number to be multiplied in arithmetic.

MULTIPLICA′TE. *a.* (from *multiplico*, Lat.) Consisting of more than one (*Derham*).

Multi′plicate flower. A multiplied flower. A sort of luxuriant flower, having the corol multiplied so far as to exclude only some of the stamens. The perianth and involucre seldom, the stamens scarcely ever, constitute a multiplicate flower. It is called a double, triple, or quadruple flower, according to the number of rows in the multiplied corol: and a double flower is the lowest degree of it, or the first essay towards fulness. In common language we improperly call all these variations double flowers.

Polypetalous flowers are not unfrequently multiplied; as in ranunculus and anemone. Monopetalous flowers are very subject to this variety; but very seldom become full, or lose all their stamens.

MULTIPLICA′TION. *s.* (*multiplicatio*, Lat.) 1. The act of multiplying or increasing any number by addition or production of more of the same kind (*Brown*). 2. (In arithmetic.) The increasing of any one number by another, so often as there are units in that number, by which the one is increased. Or, multiplication is the process by which we find a number having the same ratio to the multiplicand as the multiplier has to unity. See Arithmetic and Algebra.

MULTIPLICA′TOR. *s.* (from *multiplico*, Lat.) The number by which another number is multiplied.

MULTIPLICATUS FLOS. In botany. A luxuriant flower, whose petals are multiplied so as to exclude a part of the stamina. A multiplied luxuriant flower differs from a full one, the highest degree of luxuriance, in that the petals of the latter are so multiplied as to exclude all the stamina; whereas those of the former are only repeated or multiplied two, three, or four times, as to the exclusion of only a small part of the essential organs. See MULTIPLICATE FLOWER.

MULTIPLI'CIOUS. *a.* (*multiplex*, Lat.) Manifold: not used (*Brown*).

MULTIPLI'CITY. *s.* (*multiplicité*, Fr.) 1. More than one of the same kind (*South*). 2. State of being many (*Dryden*).

MU'LTIPLIER. *s.* (from *multiply*.) 1. One who multiplies or increases the number of any thing (*Decay of Piety*). 2. The multiplicator in arithmetic (*Cocker*).

To MU'LTIPLY. *v. a.* (*multiplico*, Lat.) 1. To increase in number; to make more by generation, accumulation, or addition (*Job*). 2. To perform the process of arithmetical multiplication (*Brown*).

To MU'LTIPLY. *v. n.* 1. To grow in number (*Wisdom*) 2. To increase themselves (*Shakspeare*).

MULTIPLYING-GLASS, in optics, one wherein objects appear increased in number. It is otherwise called a polyhedron, being ground into several planes, that make angles with each other; through which the rays of light issuing from the same point undergo different refractions, so as to enter the eye from every surface in a different direction.

MULTI'POTENT. *a.* (*multus* and *potens*, Latin.) Having manifold power (*Shakspeare*).

MULTIPRE'SENCE. *s.* (*multus* and *præsentia*, Lat.) The power or act of being present in more places than one at the same time (*Hall*).

MULTI'SCIOUS. *a.* (*multiscius*, Lat.) Having variety of knowledge.

MULTISILIQUÆ. The name of the twenty third order in the Fragments of a Natural Method, in Philos. Bot.; and of the twenty-sixth in the Ordines Naturales, at the end of Linnéus's Genera Plantarum. Comprehending those plants which have several siliques or pods succeeding to each flower. As columbine, hellebore, &c.

MULTI'SONOUS. *a.* (*multisonus*, Lat.) Having many sounds.

MU'LTITUDE. *s.* (*multitudo*, Latin.) 1. The state of being many; the state of being more than one. 2. Number collective; a sum of many (*Hale*). 3. A great number, loosely and indefinitely (*Watts*). 4. A crowd or throng; the vulgar (*Addison*).

MULTITU'DINOUS. *a.* (from *multitude*.) 1. Having the appearance of a multitude (*Shakspeare*). 2. Manifold (*Shaks.*).

MULTI'VAGANT. MULTI'VAGOUS. *a.* *multivagus*, Lat.) That wanders or strays much abroad.

MULTIVALVE GLUME. In botany, a multivalve or many-valved glume. Having more than two valves.

MULTI'VIOUS. *a.* (*multa* and *via*, Lat.) Having many ways; manifold.

MULTO'CULAR. *a.* (*multus* and *oculus*, Lat.) Having more eyes than two (*Derham*).

MULVIA, a large river of Africa, which has its source in Mount Atlas, and dividing the empire of Morocco from the kingdom of Algiers, falls into the Mediterranean Sea.

MUM, a kind of malt-liquor much drank in Germany, and chiefly brought from Brunswick, which is the place of most note for making it. The process of brewing mum, as recorded in the town-house of that city, is as follows. Take 63 gallons of water that has been boiled till one-third part is consumed, and brew it with seven bushels of wheaten malt, one bushel of oatmeal, and one bushel of ground beans. When it is tunned, the hogshead must not be filled too full at first: as soon as it begins to work, put into it three pounds of the inner rind of fir, one pound of the tops of fir and beech, three handfuls of carduus benedictus, a handful or two of the flower of rosa solis; add burnet, betony, marjoram, avens, pennyroyal, and wild thyme, of each an handful and an half; of elder-flowers, two handfuls or more; seeds of cardamum bruised, 30 ounces; barberries bruised, one ounce: when the liquor has worked a while, put the herbs and seeds into the vessel; and, after they are added, let it work over as little as possible; then fill it up: lastly, when it is stopped, put into the hogshead ten new-laid eggs unbroken; stop it up close, and use it at two years end. The English brewers, instead of the inner rind of fir, use cardamum, ginger, and sasafras; and also add elicampane, madder, and red sanders.

MUM. *interject.* A word denoting prohibition to speak; silence; hush (*Hudibras*).

To MU'MBLE. *v. n.* (*mompelen*, Dutch.) 1. To speak inwardly; to grumble; to mutter; to speak with imperfect sound (*Shaks.*). 2. To chew; to bite softly (*Dryden*).

To MU'MBLE. *v. a.* 1. To utter with a low inarticulate voice (*Shakspeare*). 2. To mouth gently (*Pope*). 3. To slubber over; to suppress; to utter imperfectly (*Dryden*).

MU'MBLER. *s.* (from *mumble*.) One that speaks inarticulately; a mutterer.

MU'MBLINGLY. *ad.* (from *mumbling*.) With inarticulate utterance.

To MUMM. *v. a.* (*mumme*, Danish.) To mask; to frolic in disguise (*Spenser*).

MU'MMER. *s.* (*mumme*, Danish.) A masker; one who performs frolics in a personated dress (*Milton*).

MU'MMERY. *s.* (*momerie*, French.) Masking; frolics in masks; foolery (*Bacon*).

MUMMY. (*mumia*, Lat. *mumie*, Fr. A mask or covering for the purpose of concealment.) A dead body preserved according to the Egyptian art of embalming, by being immersed in or stuffed with a variety of antiseptic preparations, and afterwards wrapped round with linen steeped in, or loaded with the same materials. See the article EMBALMING.

MUMMY, in mineralogy. See BITUMEN.

MUMMY (To beat to a). To beat soundly.

To MUMP. *v. a.* (*mompelen*, Dutch.) 1. To nibble; to bite quick; to chew with a continued motion (*Otway*). 2. To talk low and quick. 3. (In cant language.) To go a begging.

MU'MPER. *s.* (In cant language.) A beggar.

MUMPS. *s.* (*mompelen*, Dutch.) Sullenness; silent anger (*Skinner*).

MUMPS, in medicine, a disease of the parotid gland. See CYNANCHE.

To MUNCH. *v. a.* (*manger*, French.) To chew by great mouthfuls (*Shakspeare*).

To MUNCH. *v. n.* To chew eagerly by great mouthfuls (*Dryden*).

MU'NCHER. *s.* (from *munch*.) One that munches.

MUNCHHAUSIA, in botany, so named from baron Gerlach Adolphus de Munchhausen, a genus of the polyadelphia polyandria class and order. Natural order of calycanthemæ. Salicariæ, Jussieu. Essential character: calyx six-cleft, torulose; petals clawed; stamens in six bodies, four or five in each; pistil superior, with a filiform curved style. There is but one species, viz. M. speciosa, a native of Java and China.

MUND. *s.* Peace, from which our lawyers call a breach of the peace, *mundbrech*: so Edmund is happy peace; Æthelmund, noble peace; Ælmund, all peace (*Gibson*).

MUNDA, an ancient town of Spain, in Granada, 30 miles W.N.W. of Malaga. Lon. 4. 35 W. Lat. 36. 50 N.

MUNDA'NE. *a.* (*mundanus*, Lat.) Belonging to the world (*Glanville*).

MUNDA'TION. *s.* (*mundus*, Latin.) The act of cleansing.

MU'NDATORY. *a.* (from *mundus*, Lat.) Having the power to cleanse.

MUNDEN, or GEMUNDEN, a town of Lower Saxony, in the principality of Calenburg, situate at the confluence of the Werra and the Fulda, where they join to form the Weser. No one who is not a freeman of Munden is to trade beyond this town, but must consign his goods to a factor here; and whatever is brought in a vessel must, by virtue of the staple-right granted and confirmed to this town, be unladen and laden again. The Werra may be navigated by Munden and Hessian vessels, but the latter, on coming to Munden, are not to proceed, without a licence, and even then they must have a Munden master and pay a duty to the town. It is 10 miles N.N.E. of Cassel, and 13 S.W. of Gottingen. Lon. 9. 47 E. Lat. 51. 40 N.

MUNDER, a town of Lower Saxony, in the principality of Galenberg, situate on the Hammel, 18 miles E.S.E. of Munden. Lon. 9. 25 E. Lat. 51. 38 N.

MUNDERKINGEN, a town of Suabia, seated on the Danube, 25 miles S.W. of Ulm. Lon. 9. 43 E. Lat. 48. 15 N.

MUNDIC, in mineralogy. See CUPRUM.

MUNDIFICA'TION. *s.* (*mundus* and *facio*, Lat.) Cleansing any body, as from dross (*Quin.*).

MUNDI'FICATIVE. *a.* (*mundus* and *facio*, Latin.) Cleansing; having the power to cleanse (*Brown*).

To MU'NDIFY. *v. a.* (*mundus* and *facio*, Lat.) To cleanse; to make clean (*Harvey.*)

MUNDI'VAGANT. *a.* (*mundivagus*, Lat.) Wandering through the world.

MUNDU'NGUS. *s.* Stinking tobacco (*Phil.*)

MU'NERARY. *a.* (from *munus*, Lat.) Having the nature of a gift.

MUNGOS RADIX. Radix serpentum. This bitter root of the plant ophiorrhiza mungos of Linnéus is much esteemed in Java, Sumatra, &c. as preventing the effects which usually follow the bite of the naja, a venomous serpent, with which view it is eaten by them. It is also said to be exhibited medicinally in the cure of intestinal worms.

MU'NGREL. *s.* Any thing generated between different kinds; any thing partaking of the qualities of different causes or parents (*Shakspeare*).

MU'NGREL. *a.* Generated between different natures; base-born; degenerate (*Shak.*).

MUNICH, a city of Germany, in the circle of Bavaria, situated on the Iser, the capital and residence of the elector. The straight and broad streets of this place, and the great number of fine buildings in it, both ecclesiastical and secular, render it one of the handsomest cities in all Germany, and even in Europe; and it is said to contain 40,000 inhabitants. The palace here, which was first erected by the emperor Maximilian I, is an elegant structure, containing four courts. The things the most worthy of notice in this palace are, the large and beautiful Kaisersaal, a chapel of the Virgin Mary, with a rich treasury in it; the antiquarium, or chamber of antiquities, in which are 200 marble statues and busts of Roman emperors, and some hundreds of other antiques, the greatest part of which were brought from Italy; the chamber of rich curiosities; the musæum and the elector's library. In the year 1729, the palace, and particularly the chamber of rich curiosities here, suffered greatly by fire, and, in 1750, a whole wing of it was burned down. Towards the east stands the elector's arsenal, and northward lie the park and pleasure gardens, and near these is the Thurnierhaus, or large edifice for tournaments. In the largest market-place stands a high marble pillar, with a brass statue of the Virgin Mary upon it, and two large fountains, and on the sides is the town-house, in which the states hold their meetings, together with several lofty houses, ornamented with decorations of paintings on the front. The principal ecclesiastical buildings here are the collegiate church, and several rich convents. In Munich are manufactures of velvet, silk, wool, and tapestry. It is probable that the ancient city of Campodunum, or Campidonum, stood in this neighbourhood. About the year 1175, duke Henry the Lion built the city of Munich on a spot belonging to the convent of Schoftlar. In 1327, it was greatly damaged by fire, and in 1448, almost entirely destroyed. In 1632, it was taken by the Swedes, and in 1704, 1742, and 1743, by the Austrians, who, in the last mentioned year, established a commission of regency at this place: 200 miles W. Vienna, and twenty-nine S.E. Augsburg. Lon. 11. 36 E. Lat. 48. 10 N.

MUNICIPAL, in the Roman civil law, an epithet which signifies invested with the rights and privileges of Roman citizens. See Municipium.

Municipal, among us, is applied to the laws that obtain in any particular city or province. And those are called municipal officers who are elected to defend the interests of cities, to maintain their right and privileges, and to preserve order and harmony among the citizens; such as mayors, sheriffs, consuls, &c.

MUNICIPES, an appellation given by the Romans to the inhabitants of the *municipia* or municipal cities. See Municipium.

MUNICIPIUM, in Roman antiquity, a corporation, borough, or enfranchised city or town, where the inhabitants enjoyed their own laws and customs, and at the same time were honoured with the privileges of Roman citizens; but then this privilege generally reached no further than the bare title. Some indeed, by particular merit, obtained the liberty of votes, which occasioned that distinction of *municipium sine suffragio*, and *municipium cum suffragio*. The inhabitants of the *municipium sine suffragio* were called barely *Romani*, but those of the *municipium cum suffragio* were called *cives Romani*.

MUNIENT SLEEP. When the upper leaves of a plant, which during the day had spread out horizontally on long petioles, drop them at night, and hang down so as to form an arch all round about the stem.

MUNI′FICENCE. *s.* (*munificentia*, Lat.) Liberality; the act of giving (*Addison*).

MUNI′FICENT. *a.* (*munificus*, Latin.) Liberal; generous (*Atterbury*).

MUNI′FICENTLY. *ad.* Liberally; generously.

MU′NIMENT. *s.* (*munimentum*, Lat.) 1. Fortification; strong hold. 2. Support; defence (*Shakspeare*). 3. Record; writing upon which claims and rights are founded.

To MUNI′TE. *v. a.* (*munio*, Latin.) To fortify; to strengthen: not in use (*Bacon*).

MUNI′TION. *s.* (*munitio*, Latin.) 1. Fortification; strong hold (*Hale*). 2. Ammunition; materials for war (*Fairfax*).

MU′NNION. *s.* The upright post, that divides the lights in a window frame (*Moxon*).

MUNKACS, a town of Hungary: the castle is almost impregnable, seated on a high and steep rock, in a spacious plain, the natural strength of which is increased by art and labour. It is the capital of a lordship, formerly bearing the title of a duchy. Beneath it, on the river Latortza, is a town, which is the residence of a Greek bishop, united with the Roman church, and a convent, of the order of St. Basil. In 1688, after a blockade of three years, this famous castle surrendered to the Imperialists; count Tekely's lady, who had conducted this long defence, being carried to Vienna; and besides the Tekely family, vast treasures in money were found here. In 1703, this was the place of rendezvous to the Rakotzy party, but by suppression of that revolt, this castle escheated to the crown: fifty-two miles E.S.E. Caskau, and 128 S.S.E. Cracow. Lon. 39. 24 E. Lat. 48. 15 N.

MUNSTER (Sebastian), a learned writer, was born at Ingelheim, and became a Cordelier; but having embraced Luther's sentiments, he quitted that order in 1529, and retired to Heidelberg, and afterwards to Basil, where he taught with reputation. He was a man of great candour, and void of ambition; and was so well skilled in geography, the mathematics, and the Hebrew tongue, that he was surnamed the Esdras and the Strabo of Germany. His Latin translation of the bible is esteemed. He was the first who wrote a Chaldee grammar and lexicon: he also published a treatise on cosmography, and several other works. He died of the plague at Basil in 1552, aged 63.

Munster, in Latin *Monomia*, and in Irish *Moun*, the most southerly province of Ireland; bounded on the north by Leinster and Connaught, and on the east, west, and south, by the ocean. It contains the counties Cork, Clare, Kerry, Limerick, Tipperary, and Waterford; and 3,289,932 Irish plantation acres, 740 parishes, 63 baronies, and 26 boroughs. It is about 125 miles long, and 120 broad; and its principal town is Cork. Its ancient name was Mumhan; and in latter ages it was divided into Desmond or South Munster, Ormond or East Munster, and Thomond or North Munster. It lies between 51. 15. and 53. 0. N. lat. and 7. 10. to 10. 40. W. lon.

Munster, a sovereign bishopric of Germany, in the circle of Westphalia, 120 miles long and 80 broad; bounded on the N. by the counties of Bentheim and Steinfort, on the E. by the bishoprics of Osnaburgh and Paderborn, on the S. by the county of Marck, and on the W. by the duchy of Cleves and county of Zutphen. The river Embs runs through it from E. to W.

Munster, a large and populous city of Westphalia, capital of a bishopric of the same name, and of all Westphalia. It was free and imperial till 1661; but to keep the inhabitants in awe, a citadel was built, which stands distinct from the city. In 1533, a taylor, called John of Leyden, made himself master of the city, and drove away the bishop and magistrates; but it was retaken in 1536, after fourteen months siege, and this fanatic was tortured to death with red hot pincers. The famous treaty, called the treaty of Westphalia, was concluded here in 1648, which ended the religious wars of 30 years continuance. It is seated on the Aa, 70 miles N. by E. of Cologne, and 77 S. by W. of Bremen. Lon. 7. 39 E. Lat. 52. 0 N.

MUNTING (Abraham), an excellent botanist, who published several works, the chief of which was his Phitographia Curiosa, printed at Amsterdam in 1727. He died in 1683.

MUNTINGIA, in botany, a genus of the class polyandria, order monogynia. Calyx five-parted; corol five-petalled; berry five-celled, one-seeded. One species only: a Jamaica shrub, with hairy branches; leaves alternate, oblique, ovate-lanceolate, serrate, hoary-downy, beneath viscid; with a sphærical succulent berry.

MUNYCHIA, an anniversary solemnity observed at Athens, in honour of Diana, on the 16th of the month Munychion. Cakes were offered on the occasion called αμφιφωντες.

MUNYCHION, the tenth month of the Athenian year, containing 29 days, and answering to the latter part of our March and the beginning of April. It was so called from the festival Munychia, which was observed in this month. See Month and Munychia.

MUPHTI. See Mufti.

MURÆNA. Eel. In zoology, a genus of the class pisces, order apodalia. Head smooth; nostrils tubular; gill-membrane with ten rays: eyes covered with a common skin: body round, smooth, mucous; caudal, dorsal, and anal fins united: spiracle behind the head or pectoral fins.

In forming this genus, nature seems to have made a near approach to the reptile tribes; like these animals, the body is long, slender, and flexible. Excepting the small pair of pectoral, it may be said to have no fins; for the dorsal, anal, and tail fins are united in one web, which surrounds a large portion of the body. The apertures to the gills are small, and placed behind the pectoral fins: they are covered by ten branchiostegous rays.

The eel differs from almost every other fish of that order, of which it is placed at the top, in the manner of its generation. It is viviparous, and is impregnated in the same manner as obtains among the cartilaginous tribes. The ancients entertained very extravagant notions concerning the generation of these animals. Aristotle asserted that they were neither male nor female, had no ova nor semen. Hence it was believed that they sprung from the mud, or that the incrustations scraped from their bodies by the stones received animation. Rondeletius rashly adopted this opinion, from having observed that they were generated in pools, from which all the mud and water had been for a while extracted. This was a phenomenon, for which they could in no other way account than by the spontaneous generation of eels: but later observations have ascertained, that ponds are often supplied with these fish, in the same manner that vegetation is spread, by transporting the seeds of plants. The heron, or other water fowl, may drop the eel, when carrying it to its young, or the young may be ejected unhurt from its bowels, as the seeds of plants are voided by land birds, without being injured by the operation of the stomach.

In their habitation, the fishes of this genus are still more singular than in their manner of propagating their young. They can reside either in salt or fresh water; and what is still more surprising, they are in some measure independent of either; for they sometimes leave their native element, and wander, during night, along the dewy meadows, not only for a change of habitation, but in quest of prey. Of these nightly excursions the snail is commonly the victim, being devoured by the eel as it passes along.

There is no animal more vivacious than the eel: when drawn from the water, it will survive blows that would have killed an animal ten times its size; and even after it is cut asunder, the different parts are seen to move. It is, however, so easily destroyed by cold, that to avoid it, it beds itself deep among the mud, and continues, like the serpent tribe, in a torpid state during winter. Some have been known to take shelter under a rick of hay in severe weather, and even there, have all perished from excess of cold. Though fond of hiding themselves in the mud, they are incapable of living in thick turbid water; and hence, when a river is disturbed by a flood, they are frequently suffocated by the impurity of the stream.

The genus muræna comprises nine species, as follow:

1. M. helena. Roman eel. Without pectoral fins: body variegated. There is a variety spotted with black and green. Inhabits European and American seas; is exceedingly voracious; bites dangerously, and was regarded by the Romans as one of the greatest luxuries of the table. It was often kept in reservoirs appropriated to this purpose, and is said to have been sometimes so completely tamed as to obey the signal of its master, and come to him for food. According to Pliny, that tyrannical wretch, Vedius Pollio, was accustomed to throw his slaves, when they had displeased him, into these reservoirs, to be devoured by this voracious animal; a barbarity for which he was severely chastised by Augustus.

2. M. colubrina. Snake eel. Without pectoral fins; body alternately annulate with yellow and black bands. Another variety with brown irids spotted with black. Inhabits Amboina; and has very much the appearance of the anguis scytale.

3. M. meleagris. Speckled eel. Body blackish, thickly speckled with white. Inhabits the Southern ocean: about two feet long.

4. M. ophis. Spotted sea-serpent. Body slender, spotted; tail round, spear-shaped, naked. Inhabits European seas: from three to four feet long.

5. M. serpens. Serpent eel. Tail naked; body round; pectoral fin with about sixteen rays. Inhabits the southern European seas.

6. M. anguilla. Common eel. Lower jaw longer: body of one colour, in muddy waters black, beneath yellowish; in gravelly, clear waters, green or brownish; beneath silvery, sometimes varied with brown lines; head small, narrowed on the fore-part; mouth large; beneath each eye a small orifice, and at the end of the nose two others small and tubular; teeth small, sharp, numerous; eyes small, near the end of the nose; pupils black, iris golden; aperture of the gills semilunar;

body a little compressed; lateral line straight dotted with white; skin covered with soft oblong scales; pectoral fins small, round, paler, with about nineteen rays; dorsal, caudal, and anal fins united, frequently edged with white. Inhabits almost every where in fresh waters, but is said not to be found in the Danube or any of its branches, though plentiful in the Rhine: grows sometimes to the length of six feet, and weighs twenty pounds; in its appearance and habits something resembling the serpent tribe; during the night quits its element, and wanders along meadows in search of snails and worms; beds itself deep in the mud in winter, and continues in a state of rest; is very impatient of cold, and tenacious of life; the flesh of such as have running water very excellent: has a hundred and sixteen vertebræ; is viviparous.

7. M. mytus. Flat-tailed sea-serpent. Fin surrounding the lower part of the body white, edged with black. Another variety, entirely cinereous. Inhabits European seas. The second variety suspected of being poisonous.

8. M. conger. Conger eel. Lower jaw rather shorter than the upper: nose with two tentacles; lateral line whitish, with a row of spots.

This species often grows to an enormous size. Some specimens have been found eighteen inches in circumference, and ten feet long, weighing upwards of an hundred pounds. A fishery of congers established at Mount's Bay, in Cornwall, forms a very considerable article of commerce. They are annually exported to Spain and Portugal in a dried state, where they are grinded down into a kind of powder, and are used in enriching their soups.

They are caught by a sort of line called a bulter, baited with pilchards; when taken, they are slit up, that a part of the fat may exude from them before they are salted, and fit for use; and so considerable is the quantity of juice that thus escapes, that a fish of a hundred weight will not dry to above twenty-five pounds. M. Pennant supposes that a fishery of congers might be established with advantage in the Hebrides, could the aversion of the natives to this tribe be overcome.

This species is distinguished by the same voracity as the former; it devours other fish, crabs, and even carcases. The mode of its generation is probably the same with the common eels; but, however this be, it is certainly prolific, for the number of its young that annually ascends the Severn is prodigious; they are there called elvers, and during the month of April swarm in such shoals, that they are thrown out upon the shore with small sieves made of hair, and fixed to the end of a pole: a man will in this manner take out as many at one tide as will fill a bushel.

9. M. gattata. Glaucous, speckled with black, with a larger spot on each side near the head. Inhabits Arabia. See Nat. Hist. Pl. CLVII.

MU'RAGE. *s.* (from *murus*, Latin.) Money paid to keep walls in repair.

MU'RAL. *a.* (*muralis*, Lat.) Pertaining to a wall (*Evelyn*).

MURAL-CROWN, among the ancient Romans. See CROWN.

MURAL-ARCH, is a wall, or walled arch, placed exactly in the plane of the meridian, i. e. upon the meridian line, for the fixing of a large quadrant, sextant, or other instrument, to observe the meridian altitudes, &c. of the heavenly bodies. Tycho Brahe was the first who used a mural arch in his observations; after him Hevelius, Mr. Flamstead, De la Hire, &c. used the same means.

MURAL QUADRANTS have usually been made from five to eight feet in radius. The figure in the upper part of plate 116 represents the instrument as already fixed to the wall. The frame is formed of flat bars, and strengthened by edge bars affixed underneath perpendicularly to them. The radii HB, HA, being divided each into four equal parts, serves to find out the points D and E, by which the quadrant is freely suspended on its props or iron supports that are fastened securely in the wall.

One of the supports E is represented separately in *e* on one side of the quadrant. It is moveable by means of a long slender rod EF or *e f*, which goes into a hollow screw in order to restore the instrument to its situation when it is discovered to be a little deranged. This may be known by the very fine perpendicular thread HA, which ought always to coincide with the same point A of the limb, and carefully examined to be so by a small magnifying telescope at every observation. In order to prevent the unsteadiness of so great a machine, there should be placed behind the limb four copper ears with double cocks I, K, I, K. There are others along the radii HA and HB. Each of these cocks contains two screws, into which is fastened the ears that are fixed behind the quadrant.

Over the wall or stone which supports the instrument, and at the same height as the centre, is placed horizontally the axis PO, which is perpendicular to the plane of the instrument, and which would pass through the centre if it was continued. This axis turns on two pivots P. On this axis is fixed at right angles another branch ON, loaded at its extremity with a weight N capable of equipoising with its weight that of the telescope LM; whilst the axis, by its extremity nearest the quadrant, carries the wooden frame PRM, which is fastened to the telescope in M. The counterpoise takes off from the observer the weight of the telescope when he raises it, and hinders him from either forcing or straining the instrument.

The lower extremity (V) of the telescope is furnished with two small wheels, which take the limb of the quadrant on its two sides. The telescope hardly bears any more upon the limb than the small friction of these two wheels: which renders its motion so extremely easy and pleasant, that by giving it with the hand only a small motion, the telescope will run of itself over a great part of the limb, balanced by the counterpoise N.

When the telescope is to be stopped at a certain position, the copper hand T is to be made use of, which embraces the limb and springs at the bottom. It is fixed by setting a screw, which fastens it to the limb. Then, in turning the regulating screw, the telescope will be advanced; which is continued until the star or other object whose altitude is observing be on the horizontal fine thread in the telescope. Then on the plate X. supporting the telescope, and carrying a vernier or nonius, will be seen the number of degrees and minutes, and even quarter of minutes, that the angular height of the object observed is equal to. The remainder is easily estimated within two or three seconds nearly.

There are several methods of subdividing the divisions of a mural quadrant, which are usually from five to ten minutes each; but that which is most commonly adopted is by the vernier or nonius, the contrivance of Peter Vernier a Frenchman. This vernier consists of a piece of copper or brass, CDAB, which is a small portion of X, represented separately. The length CD is divided into 20 equal parts, and placed contiguously on a portion of the division of the limb of the quadrant containing 21 divisions, and thereby dividing this length into 20 equal parts. Thus the first division of the vernier piece marked 15, beginning at the point D, is a little matter backward, or to the left of the first division of the limb, equal to 15″. The second division of the vernier is to the left of the second division of the limb double of the first difference, or 30″; and so on unto the twentieth and last division on the left of the vernier piece; where the 20 differences being accumulated each of the twentieth part of the division of the limb, this last division will be found to agree exactly with the 21st division on the limb of the quadrant.

The index must be pushed the 20th part of a division, or 15″, to the right; for to make the second division on the vernier coincide with one of the divisions of the limb, in like manner is moving two 20ths, or 30″, we must look at the second division of the index, and there will be a coincidence with a division of the limb. Thus may be conceived that the beginning D, of the vernier, which is always the line of reckoning, has advanced two divisions, or 30″, to the right, when the second division, marked 30 on the vernier, is seen to correspond exactly with one of the lines of the quadrant.

On the side of the quadrant is placed the plate of copper which carries the telescope. This plate carries two verniers. The outer line CD divides five minutes into 20 parts, or 15″ each. The interior line AB answers to the parts of another division not having 90°, but 96 parts of the quadrant. It is usually adopted by English astronomers on account of the facility of its subdivisions. Each of the 96 portions of the quadrant is equivalent to 56′15″ of the usual divisions. It is divided on the limb into 16 parts, and the arch of the vernier AB contains 25 of these divisions; and being divided itself into 24, immediately gives parts, the value of each of which is 8″ 47½‴. See Nonius and Vernier.

MURANT (Emanuel), a much-admired landscape painter, was born at Amsterdam in 1622 He had the happiness to be a disciple of Philip Wouwermans, from whom he acquired that warmth and brilliancy of colouring, and that exquisite pencil, which have rendered him deservedly eminent. His subjects were views in Holland, villages, towns, cities, ruins of houses, and decayed castles; all of them exactly sketched after nature, and so exquisitely finished, that every minute part of a building was perfectly discernible, and even every particular stone or brick might be counted by the assistance of a convex glass. But this demanded so much patience and time, that it was impossible for him to paint many pictures; and on that account they are exceedingly scarce, and sold for such prices as must place them out of the reach of all ordinary purchasers. He died in 1700.

MURATORI (Louis Anthony), an Italian writer, was born near Bologna in 1672. The duke of Modena made him his librarian, and keeper of the archives of his duchy. He died in 1750, leaving several learned works behind him, the chief of which are, 1. Rerum Italicarum Scriptores ab Ann. 500 ad. 1500, 27 vols. fol.; 2. Antiquitates Italicæ medii Ævi, sive Dissertationes de moribus Italici Populi, ab inclinatione Romani imperii, usque ad An. 1500, 6 vols. fol.

MURCIA, the pagan goddess of idleness. The name is taken from *murcus* or *murcidus*, an obsolete word, signifying a dull, slothful, or lazy person. The statues of this goddess were always covered with dust and moss, to express her idleness and negligence. She had a temple in Rome, at the foot of the Aventine mount.

Murcia, a kingdom in Spain, bounded on the north by New Castile, on the east by the kingdom of Valencia, on the west by Andalusia and Granada, and on the south by the Mediterranean Sea. It is about 62 miles in length, and 58 in breadth; and its principal river is Segura. The soil is dry, because it seldom rains, and therefore it produces little corn or wine; but there is plenty of oranges, citrons, lemons, olives, almonds, mulberries, rice, pulse, and sugar. It has also a great deal of silk. It was taken from the Moors in 1265. The air is very healthful.

Murcia, a large, handsome, and populous town of Spain, capital of a kingdom of the same name. It is a bishop's see, and contains six parishes. The cathedral is a most superb edifice, with the stairs of the steeple so contrived that a man may ride up to the top, either on horseback or in a coach. It is situated in a pleasant plain, which abounds in fine gardens about the city, in which are the best fruits in Spain. It is seated on the river Segura, in lon. 0. 36 W. Lat. 37. 48 N.

MURDER, or MURTHER, the act of killing another with violence and injustice. The word comes from the Saxon *morth*, death; which some will have to signify a violent death; whence the barbarous Latin *murdrum* or *mordrum*. Among the number of popular errors is the notion which has obtained, that the dead body would bleed in the presence or upon the touch of the murderer. The crime of murder is punished with death in almost all nations. See HOMICIDE and MANSLAUGHTER.

The punishment of murder, and that of manslaughter, were formerly one and the same; both having the benefit of clergy: so that none but unlearned persons, who least knew the guilt of it, were put to death for this enormous crime. But now, by several statutes, the benefit of clergy is taken away from murderers through malice prepense, their abettors, procurers, and counsellors. In atrocious cases it was frequently usual for the court to direct the murderer, after execution, to be hung upon a gibbet in chains near the place where the fact was committed; but this was no part of the legal judgment; and the like is still sometimes practised in the case of notorious thieves. This, being quite contrary to the express command of the Mosaical law, seems to have been borrowed from the civil law; which, besides the terror of the example, gives also another reason for this practice, viz. that it is a comfortable sight to the relations and friends of the deceased. But now in England, it is enacted by statute 25 Geo. II. c. 37. that the judge, before whom any person is found guilty of wilful murder, shall pronounce sentence immediately after conviction, unless he sees cause to postpone it; and shall in passing sentence direct him to be executed on the next day but one (unless the same shall be Sunday, and then on the Monday following), and that his body be delivered to the surgeons to be dissected and anatomized; and that the judge may direct his body to be afterwards hung in chains, but in nowise to be buried without dissection. And, during the short but awful interval between sentence and execution, the prisoner shall be kept alone, and sustained with only bread and water. But a power is allowed to the judge, upon good and sufficient cause, to respite the execution, and relax the other restraints of this act.

To MU'RDER. *v. a.* (from the noun.) 1. To kill a man unlawfully (*Dryden*). 2. To destroy; to put an end to (*Shakspeare*).

MU'RDERER. *s.* (from *murder.*) One who has shed human blood unlawfully (*Sidney*).

MU'RDERESS. *s.* (from *murder.*) A woman that commits murder (*Dryden*).

MU'RDERMENT. *s.* (from *murderer.*) The act of killing unlawfully: not used (*Fairf.*).

MU'RDEROUS. *a.* Bloody; guilty of murder; addicted to blood (*Prior*).

MURE. *s.* (*mur*, French; *murus*, Latin.) A wall: not in use (*Shakspeare*).

To MURE. *v. a.* To enclose in walls (*Knolles*).

MU'RENCER. *s.* (*murus*, Latin.) An overseer of a wall (*Ainsworth*).

MURETUS (Marc Anthony), a learned critic, was born at Muret near Limoges, in France, in 1526. He recited in 1552, in the church of the bernardines at Paris, an oration De dignitate ac præstantia studii theologici, but, the year following, was thrown into prison for an unnatural crime. However he was released, and went to Toulouse, where he read lectures in civil law; but was there guilty of the same offence, on which he fled into Italy, and in 1576 entered into orders. He died in 1585. His works have been printed in several volumes: they consist of orations, poems, epistles, and translations of Greek authors.

MUREX. Purple-fish. In zoology, a genus of the class vermes, order testacea. Animal a limax; shell univalve, spiral, rough with membranaceous sutures; aperture oval, ending in an entire, straight or slightly ascending canal. A hundred and eighty-one species, scattered through the different seas of the globe; seven or eight common to our own coasts. They may be thus subdivided:

A. Spinous, with a produced beak: of which the most valuable is,

1. M. tribulus; thorny woodcock. Shell ovate with a triple row of setaceous spines, the beak elongated, subulate with similar spines; shell whitish, or reddish, transversely striate. Inhabits Asia, America, and the Red sea: very rare.

B. Sutures expanding into crisped foliations; beak abbreviated; constituting the tribe of purpura, of purple-fish properly so called. This tribe includes thirteen species, chiefly inhabitants of Asia and America.

C. With thick, protuberant, rounded sutures. Twenty-two species, chiefly of the Eastern or Pacific seas: some mere fossils.

D. More or less spinous, and without manifest beak. The following is worthy of notice:

2. M. loco. Shell subovate and knotty on the fore-part; aperture toothless and suborbicular. Inhabits the Chinese shores: shell about four or five inches long: the animal often eaten by the natives, and contains a purple juice in a vesicle on the neck.

E. With a long, straight, subulate closed beak, unarmed with spines. A very numerous subdivision. The following are the chief:

3. M. despectus. Beak dilated; shell oblong, striate, and somewhat rugged: whorls eight, with two elevated lines. Inhabits the seas of Europe, and often found on our own coasts; about five inches long: shell coarse, white, with a glossy orange-yellow aperture: the worm is sometimes eaten, but oftener used as a bait for cod and ray-fish.

4. M. tritonis. Musical murex. Shell ventricose, oblong, smooth, with rounded whorls, toothed aperture, and short beak: about fifteen inches long, white, and appearing as if covered with brown, yellow and black scales; pillar white, with transverse black striæ; whorls of the spire separated by a nodulous suture, the first marked with striate grooves.

Inhabits India and the South seas: a second variety the Mediterranean. This is the species used by the natives of New Zealand as a musical shell, and by the Africans and many nations of the east as a military horn.

F. Tapering, subulate, with a very short beak. The following is worth noticing:

5. M. minutissimus. Shell with five spirally striate whorls and remote ribs; beak closed. Inhabits the Welsh coast: the shell is very minute, elegant and pellucid.

MURIA, in mineralogy, a genus of the class salts. Of a salt taste, easily soluble in water, and the solution not made turbid by soda: not effervescing with diluted acids, but effervescing and emitting grey, ill-savoured, suffocating vapours in strong, hot, sulphuric acids: changing nitrous acid into nitro-muriatic acid. Nine species.

1. M. aquatica. Fixed, decrepitating when heated, of a cubic form, dissolved in water. Three varieties.

α. Held in solution in the waters of the ocean: sea-salt; the muria marina of Wall. and the Syst. Nat.; or sal marinum of Cronsted.

β. Held in solution in salt lakes, muria lacustris: sal marinum lacuum.

γ. Held in solution in salt springs. Spring-salt: the muria fountana of Waller and the Syst. Nat.; the sal fontanum of Cronsted.

Found in the ocean, salt lakes, &c.; and when evaporated generally contains from 20 to 30 per cent. of muriat of soda.

2. M. montana. Fossil muria. Common salt. Sal gem. Rock salt. Muriat of soda. Several varieties.

α. Crystallized in cubes.

β. Of a common form, sometimes fibrous, sometimes compact.

γ. In a stalactitical form.

Found in Britain, Poland, Hungary, Spain, and various other countries, sometimes forming vast masses and mountains: it is found colourless, and of various shades of grey, yellow, red, blue, or brown; frequently contaminated by a mixture of muriat of lime, muriat of magnesia, or other earths, and may be purified by dropping into it first a solution of carbonat of barytes, then of carbonat of soda, as long as any precipitate continues to fall; the precipitate should then be separated by filtration and evaporated slowly till the salt crystallizes: it is soluble in something less than three times its weight of water: spec. grav. 2,120: contains

Acid - - -	52
Soda - - -	42
Water of crystallization	6
	100 *Bergman.*

3. M. impura. Muriat of alumina. Earthy mineral muria. Fixed, decrepitating in the fire, dry, producing sulphat of soda when saturated with sulphuric acid, mixed with various earths. Found in the Nevil Holt waters and in the salt-pits of Salsburg, and is a coarser variety of the last from its being much mixed with gypsum, common mould, clay, and other earths; its taste is astringent.

4. M. febrifuga. Muriat of potash, or potass. Muriated tartarin. Salt of silvius. Fixed, decrepitating in the fire, forming muriat of potash with sulphuric acid. Found in the environs of Madrid, and some mineral waters in Normandy; has a disagreeable bitterish taste, and when dissolved and crystallized forms cubes which are often irregular; formerly known in the shops by the name of febrifuge or digestive salt: specific gravity 1,836: contains

Acid - - - -	31
Potash - - -	61
Water - - - -	8
	100 *Bergman.*

5. M. ammoniaca. Sal ammoniac. Muriat of ammonia. Of an acid pungent urinous taste, when heated subliming into a white smoke, rubbed with quick-lime exhaling an alkaline odour, its crystals deliquescing in the air. Two varieties.

α. Concrete in flowers or thin layers.

β. Concrete in small compact masses.

Found in coal-pits in various parts of Britain, but principally in the interior parts of Asia and Africa, and in the neighbourhood of volcanoes; rarely pure, white and transparent, generally of a yellowish-grey, apple-green, or brownish-black colour; it dissolves in about three times its weight of water, and when slowly evaporated forms flexible spicules connected like the web of a feather: spec. grav. 1,420: contains

Acid - - -	42,75
Ammonia - -	25,00
Water - - -	32,25
	100,000 *Kirwan.*

6. M. barytes. Muriat of barytes. Muriated baryt. Fixed, decrepitating in the fire, of an acrid astringent taste, precipitating sulphat of baryt when dropped into a weak solution of suphuric acid. Found in some mineral waters of Sweden, and when evaporated forms four-sided prisms, whose bases are squares or tables: sometimes used in scrophulous affections in doses of from 5 to 20 drops; but much precaution is necessary in its exhibition, as, like all other barytic salts, it is poisonous: spec. grav. 28527: contains in a state of crystallization,

Acid - - -	20
Barytes - - -	64
Water - - -	16
	100

When dried contains,

Acid - - -	23,8
Barytes - - -	76,2
	100 *Kirwan.*

7. M. strontiana. Muriat of strontian. Of a sharp penetrating taste, when heated undergoing a watry fusion and afterwards becoming a white powder, precipitated from its watry

solution by muriatic acid. Never perhaps found naturally combined, but prepared by dissolving carbonat of strontian in muriatic acid: spec. grav. 14,402: contains

Acid - - -	23,6
Strontian - -	36,4
Water - - -	40,0
	100 *Bergman.*

8. M. calcarea. Muriated calx. Muriated lime. Of a bitter taste, swelling and melting and losing its water of crystallization in heat, and after having been exposed to a violent heat shining in the dark. Found in mineral waters, but generally combined with common sea-salt, to which it gives a bitterish taste, and which it causes to attract moisture, and melt speedily in the air; its crystals are six-sided striate prisms, terminated by very sharp pyramids; its earth is precipitated by sulphuric acid: specific gravity 1,76: contains

Acid - - -	31
Lime - - -	44
Water - - -	25
	100 *Bergman.*

9. M. magnesiata. Muriated magnesia. Muriat of magnesia. Found in salt and other mineral springs, and abounds in the waters of the sea; its solution precipitated by caustic alkalies, and not visibly by the sulphuric: it deliquesces very speedily in the air, and when dried in a high temperature is very caustic: specific gravity 1,601: contains

Acid - -	34
Magnesia - -	41
Water - - -	25
	100 *Bergman.*

MURIAS BARYTÆ. Terra ponderosa salita. In medicine. The muriate of barytes, or heavy earth, is a very acrid and poisonous preparation. In small doses it proves sudorific, diuretic, deobstruent, and alterative; in an overdose, emetic, and violently purgative. The late Dr. Crawford found it very serviceable in all diseases connected with scrophula; and the Germans have employed it with great success in some diseases of the skin and viscera, and obstinate ulcers. The dose of the saturated solution in distilled water, is from five to fifteen drops for children, and from fifteen to twenty for adults.

Murias calcis. Calx salita. Sal ammoniacus fixus. This preparation is exhibited with the same views as the muriate of barytes. It possesses deobstruent, diuretic, and cathartic virtues, and is much used by the celebrated Fourcroy against scrophula, and scrophulous diseases. Six, twelve, and twenty grains are given to children three times a day, and a drachm to adults.

Murias ferri. Ferrum salitum. Oleum martis per deliquium. This preparation of iron is styptic and tonic, and may be given in chlorosis, intermittents, rachitis, &c.

Murias ferri ammoniacalis. See Ferrum ammoniacale.

Murias hydrargyri. There are two simple muriates of mercury. See Calomelas, and Hydrargyrus muriatus mitis.

Murias hydrargyri ammoniacalis. See Calx hydrargyri alba.

Murias hydrargyri oxygenatus. See Hydrargyrus muriatus.

Murias hyperoxygenatus potassæ. The oxygenated muriate of potash has lately been extolled in the cure of the venereal disease. It is exhibited in doses of from fifteen to forty grains in the course of a day. It increases the action of the heart and arteries, oxygenates the blood, and proves of great service in scorbutus, asthenia, cachexia, &c.

Murias potassæ. Alkali vegetabile salitum. Sal digestivus. Sal febrifugus sylvii. This salt is exhibited with the same intention as the muriate of soda, and was formerly in high estimation in the cure of intermittents, &c.

Murias sodæ. Alkali minerale salitum. Sal commune. Sal culinaris. Sal fontium. Sal gemmæ. Sal marinus. Natron muriatum. Soda muriata. Common sea salt, possessing antiseptic, diuretic, and resolvent qualities, and frequently employed in form of clyster, fomentation, lotion, pediluvium, and bath, in obstipation, against worms, gangrene, scrophulous tumours, herpetic eruptions, arthritis, &c.

Murias stibii hyperoxygenatus. See Antimonium muriatum.

MURIATS. (*murias.*) Salts formed by the union of the muriatic acid with different bases; thus, muriat of ammoniac, muriat of copper, &c.

Muriat of alumina. See Muria.

Muriat of ammonia. See Muria.

Muriat of antimony. See Stibium.

Muriat of barytes. See Muria.

Muriat of copper. See Cuprum.

Muriat of lime. See Muria.

Muriat of magnesia. See Muria.

Muriat of mercury. See Hydrargyrum.

Muriat of potash. See Muria.

Muriat of silver. See Argentum.

Muriat of soda. See Muria.

Muriat of strontian. See Muria.

MURIATIC ACID. An acid obtained from muria or the basis of sea-salt by means of distillation with sulphuric acid. It is an invisible elastic fluid resembling air in its common properties. According to Mr. Davy's latest experiments, this is not a simple substance, though placed so in all our systematic treatises of chemistry, but a compound of a substance which has never yet been procured in an uncombined state, and of from a third to a fourth of water. See Phil. Trans. for 1809, p. 468.

Its use in the laboratory is very considerable; but in medicine and the arts it is but little employed except in the form of muriat, or combined with some salifiable base. It is worth remembering by the chemist that nothing takes off the crust of oxyd of iron, which in many experiments is found adhering with remarkable closeness to glass vessels, so safely and so quickly as a little warm dilute muriatic acid.

This acid may be procured by the following process: Let a small pneumatic trough be procured, hollowed out of a single block of wood about 14 inches long, seven broad, and six deep. After it has been hollowed out to the depth of an inch, leave three inches by way of shelf on one side, and cut out the rest to the proper depth, giving the inside of the bottom a circular form. Two inches from each end cut a slit in the shelf to the depth of an inch, and broad enough to admit the end of small glass tubes, or the points of small retorts. This trough is to be filled with mercury to the height of one quarter of an inch above the surface of the shelf. Small glass jars are to be procured of considerable thickness and strength, and suitable to the size of the trough. One of them, being filled with mercury by plunging it into the trough, is to be placed on the shelf over one of the slits. It ought to be supported in its position; and the most convenient method of doing that is to have a brass cylinder two inches high screwed into the edge of the trough, just opposite to the border of the shelf. On the top of it are fixed two flat pieces of brass, terminating each in a semicircle, moveable freely upon the brass cylinder, and forming together a brass arm terminating in a circle, the centre of which is just above the middle of the slit in the shelf, when turned so as to be parallel to the edge of the shelf. This circle is made to embrace the jar: being formed of two distinct pieces, its size may be increased or diminished at pleasure; and by means of a brass slider it is made to catch the jar firmly.

The apparatus being thus disposed, two or three ounces of common salt are to be put into a small retort, and an equal quantity of sulphuric acid added; the beak of the retort plunged below the surface of the mercury in the trough, and the heat of a lamp applied to the salt in its bosom. A violent effervescence takes place; and air-bubbles rush in great numbers from its beak, and rise to the surface of the mercury in a visible white smoke, which has a peculiar odour. After allowing a number of them to escape, till it is supposed that the common air which previously existed in the retort has been displaced, plunge its beak into the slit in the shelf over which the glass jar has been placed. The air-bubbles soon displace the mercury and fill the jar. The gas thus obtained is called muriatic acid gas.

This substance, in a state of solution in water, was known even to the alchemists; but in a gaseous state it was first examined by Dr. Priestley, in an early part of that illustrious career in which he added so much to our knowledge of gaseous bodies.

1. Its specific gravity, according to the experiments of Mr. Kirwan, is 0.002315, or nearly double that of common air. Its smell is pungent and peculiar; and whenever it comes in contact with common air, it forms with it a visible white smoke. If a bottle of it is drawn into the mouth, it is found to taste excessively acid; much more so than vinegar.

2. Animals are incapable of breathing it, and when plunged into jars filled with it, they die instantaneously in convulsions. Neither will any combustible burn in it. It is remarkable, however, that it has a considerable effect upon the flame of combustible bodies; for if a burning taper is plunged into it, the flame, just before it goes out, may be observed to assume a green colour, and the same tinge appears next time the taper is lighted.

3. If a little water is let up into a jar filled with this gas, the whole gas disappears in an instant, the mercury ascends, fills the jar, and pushes the water to the very top. The reason of this is, that there exists a strong affinity between muriatic acid gas and water; and whenever they come in contact, they combine and form a liquid, or, which is the same thing, the water absorbs the gas. Hence the necessity of making experiments with this gas over mercury. In the water cistern not a particle of gas would be procured. Nay the water of the trough would rush into the retort and fill it completely. It is this affinity between muriatic acid gas and water which occasions the white smoke that appears when the gas is mixed with common air. It absorbs the vapour of water which always exists in common air. The solution of muriatic acid gas in water is usually denominated simply muriatic acid by chemists.

4. If a little of the blue-coloured liquid which is obtained by boiling red cabbage-leaves and water is let up into a jar filled with muriatic acid gas, the usual absorption of the gas takes place, but the liquid at the same time assumes a fine red colour. This change is considered by chemists as a characteristic property of acids.

5. Muriatic acid gas is capable of combining with oxygen. To obtain the combination, we have only to put a quantity of the black oxide of manganese in powder into a retort, and pour over it liquid muriatic acid. Heat is then to be applied to the mixture, and the beak of the retort plunged under water. An effervescence takes place, and a green-coloured gas comes out at the beak of the retort, which may be received in the usual manner in jars. This gas has been ascertained to be a compound of muriatic acid and oxygen. It is called oxy-muriatic acid, and will come under our consideration hereafter.

6. It does not appear from any experiments that have been hitherto made, that any of the simple combustibles are capable of combining with muriatic acid gas. Dr. Priestley found, that sulphur absorbed slowly about the fifth part of it. What remained was inflammable air, burning with a blue flame, and not absorbed by water. He found that phosphorus scarcely absorbed any sensible quantity of it, and that charcoal absorbed it very fast. Hydrogen gas does not produce any sensible change in it. Neither does it seem capable of being affected by azotic gas.

Muriatic acid is capable of combining with two doses of oxygen only. With the first dose, it forms oxymuriatic acid; with the second, hyperoxymuriatic acid. The first of them ought, in strict propriety, to be termed an oxide rather than an acid.

MURICATE. Muricated. In botany, punctis subulatis adspersus. Having subulate points scattered over; or armed with sharp prickles, like the murex shell-fish. Applied to the stem—to the calyx, as in crepis biennis—to the pod, as in bunias—to the seeds, as in caucalis, ammi. Hence we have

Muricatæ for the name of the eleventh order in Linnéus's fragments of a natural method.

MURILLO (Bartholomew), a Spanish painter, born at Pilas, near Seville, in 1610, and died at Madrid in 1685. Though he painted historical pieces and landscapes, yet his favourite subjects were beggar boys in different actions and amusements. He was equal to Paul Veronese; and the king of Spain had so great an admiration of his talents, as to give him a patent of nobility.

MURK. *s.* (*morck*, Danish.) Darkness; want of light (*Shakspeare*).

Murk. *s.* Husks of fruit (*Ainsworth*).

MU'RKY. *a.* (*morck*, Danish.) Dark; cloudy; wanting light (*Addison*).

MU'RMUR. *s.* (*murmur*, Latin.) 1. A low shrill noise (*Pope*). 2. A complaint half suppressed (*Dryden*).

To Mu'rmur. *v. n.* (*murmuro*, Latin.) 1. To give a low shrill sound (*Pope*). 2. To grumble; to utter secret and sullen discontent (*Swift*).

MU'RMURER. *s.* (from *murmur.*) One who repines; a grumbler; a repiner (*Blackm.*).

MU'RNIVAL. *s.* Four cards of a sort.

MU'RRAIN. *s.* The plague in cattle (*Garth*).

MURRAY (William, earl of Mansfield), was fourth son of David, earl of Stormont, and born at Perth in 1705. He received his education at Westminster school, and was elected off for Christchurch in 1723. Here he took his degrees in arts, and then went abroad. On returning from his travels he became a member of Lincoln's-Inn, and in due course was called to the bar. He soon distinguished himself as an advocate, and in 1742 was appointed solicitor-general, and chosen into parliament for Boroughbridge. In 1754 he was made attorney-general, and in 1756 chief justice of the King's-Bench. He was soon after created baron of Mansfield. The year following he accepted the office of chancellor of the exchequer, which was done merely to effect a coalition of parties; and thereby an administration was formed, which carried the glory of the British arms to an unrivalled pitch. At the commencement of the present reign lord Mansfield was shamefully insulted in numerous libels, and in the affair of Mr. Wilkes he was exposed to the malicious attacks of party and faction. In 1776 he was created earl of Mansfield, with remainder to Louisa, viscountess Stormont, and her heirs male. In 1780, when the metropolis was a scene of lawless riot, his lordship's house in Bloomsbury-square was burnt down by the mob, and he escaped with difficulty. A vote of the house of commons was passed to make him a compensation for his loss, but he generously refused to accept of any reparation. In June, 1788, age and infirmities compelled him to resign his office, on which occasion he was addressed in a most respectful letter by the bar, which was transmitted to him by Mr. (now lord) Erskine. This great man died in 1793, and was buried in Westminster abbey. As he left no children, his earldom descended to his nephew lord Stormont.

Murray frith, a large bay of the German Sea, on the east coast of Scotland, and north of the county of Murray, whence its name.

Murray harbour, a harbour on the east coast of the island of St. John, in the Gulf of St. Lawrence. Lon. 62. 20 W. Greenwich. Lat. 46. N.

Murray's islands, several small islands on the south-west coast of the county of Kircudbright, at the mouth of Fleet bay: eleven or twelve miles N.N.E. Burrow Head.

MURRAYSHIRE, or Elginshire, a county of Scotland, bounded on the north by an arm of the sea, called the Frith of Murray, on the east by Banffshire, on the south by Aberdeenshire and Invernessshire, and on the west by Invernessshire and Nairnshire; being thirty miles from east to west, and nearly the same from north to south. Its air is salutary, and the winter milder than any other part in the north of the kingdom. The south side is mountainous, but abounds with pasture, as the low country does with corn. Here are several woods of firs and oaks. The soil is generally fruitful, and produces the fruits ripe soon. Its principal rivers are the Spey, the Lossie, Nairn, and Findhorn; all of which produce vast quantities of salmon. The chief towns are Elgin and Forres.

MURRAYA, in botany, a genus of the class decandria, order monogynia: calyx five-parted; corol five-petalled, campanulate; nectary surrounding the germ; berry one-seeded. One species only: an East Indian tree with alternate pinnate leaves.

MU'RREY. *a.* (*morée*, French.) Darkly red (*Boyle*).

MURRHINE, Murrhinus, Μοῤῥινος, in antiquity, an appellation given to a delicate sort of ware brought from the east, whereof cups and vases were made, which added not a little to the splendor of the Roman banquets. Critics are divided concerning the matter of the pocula, or vasa murrhina, murrina, or murrea. Some will have them to have been the same with our porcelain or china-ware. The generality hold them to have been made of some precious kind of stone, which was found chiefly, as Pliny tells us, in Parthia, but more especially in Carmania. Arrian tells us, that there was a great quantity of them made at Diospolis in Egypt. This he calls another sort of murrhina work; and it is evident, from all accounts, that the murrhina of Diospolis was a sort of glass-ware, made in imitation of the porcelain or murrha of India.

There is some difference in the accounts given by Pliny and Martial of the murrhina vasa. The first author says, that they would not bear hot liquors, but that only cold ones were drank out of them. The latter, on the other hand, tells us, that they bore hot liquors very well. If we credit Pliny's account, their procelain was much inferior to ours in this particular. Some conjecture them to have been of agate, others of onyx, others of coral.

MU'RRION. *s.* (often written *morion.*) A helmet; a casque (*King*).

MURTH *of Corn.* *s.* Plenty of grain (*Ainsworth*).

MUS. Rat. In zoology, a genus of the class mammalia, order glires. Fore-teeth upper, wedged: grinders three, rarely two, on each side of each jaw; clavicle perfect. These animals live in holes or any concealed chinks, climb and run swiftly; seek their food by night, which is chiefly vegetable, and which they convey to the mouth by the fore-paws. The females have mostly eight teats, breed many times a year, bring numerous litters. Some of them migrate. The ears are short and rounded; fore-feet generally four-toed, with a warty excrescence instead of a fifth. Forty-six species scattered over the globe: six indigenous to our own country: they may be thus subdivided:

A. Tail compressed at the end.
B. Tail round, naked.
C. Tail round, hairy.
D. Cheeks pouched.
E. Earless; eyes small: tail short, or none; subterraneous.

The following are chiefly entitled to notice:

1. M. coypus. Beaver rat. Tail middle length, subcompressed, hairy: hind-feet palmate. Inhabits the waters of Chili: was first described by Molina; has a general resemblance to the other in size and colour, but in its teeth agrees with the rat tribe; is easily tamed. The female produces five or six young at a birth.

2. M. zibethicus. Musk rat. Tail long, compressed, lanceolate; feet cleft; anus with glands secreting a musky oily fluid. Inhabits the slow streams of North America, on the banks of which it builds, but more simply than the beaver: feeds on shell-fishes, in summer on fruit and herbs, in winter on roots, particularly of flags, and water-lilies. The female has six abdominal teats, and brings from three to six young, three or four times a year; swims and dives dextrously; walks unsteadily; a foot long.

3, M. pilorides. Musk cavy. Tail longish, scaly, truncate; body white. Another species tawny above. The first inhabits India; the second the West-Indies; burrows; infests houses; smells of musk; size of a rabbit; tail four inches long.

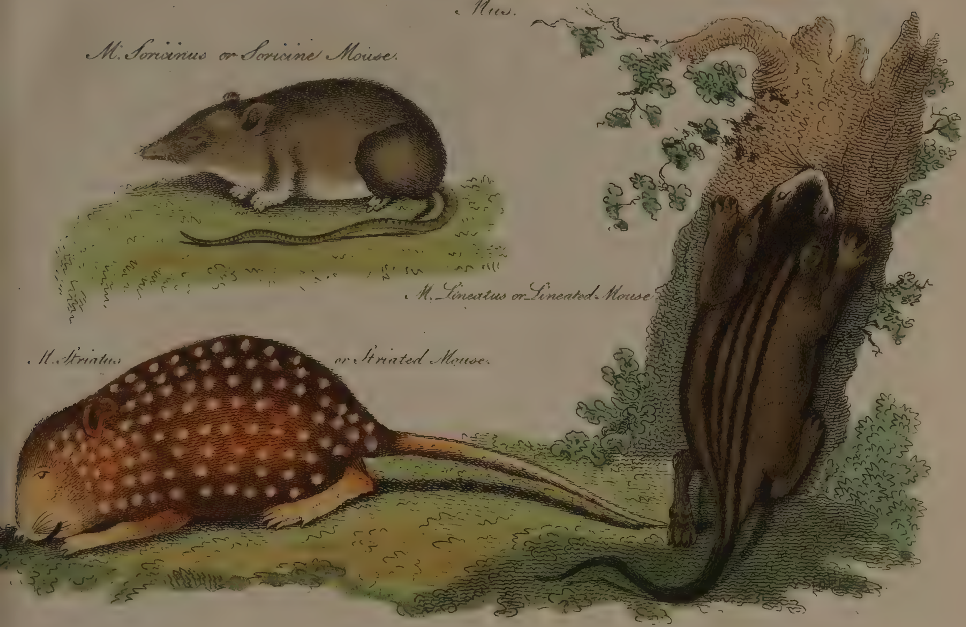
4. M. rattus. Black rat. Of a deep iron grey colour, nearly black. Belly cinereous; legs dusky, almost naked. Has a claw in the place of a fifth toe on the fore feet. Its body measures seven inches; its tail near eight. It inhabits most parts of Europe. Its numbers are much lessened, and in many places indeed extirpated, by the M. decumanus. This species is very destructive to corn, furniture, young poultry, rabbits, and pigeons. It will even gnaw the extremities of infants when asleep. It breeds often in a year, and brings six or seven young at a time. Makes its nest in a hole, often near a chimney, with wool, bits of cloth, or with straw. Will destroy and devour one another; but its greatest enemy is the weasel. It was carried into South America about the year 1544, by the Europeans, and is now become the pest of all that continent. The word rattus, or rat, is modern. The Romans probably comprehended all kinds under the word mus. The Welsh call it the French mouse, which intimates that it has been imported thence into our island. None of them are found in Siberia. They swarm at Otaheite, and others of the Society Islands, and are met with in New Zealand and New Holland. In Otaheite they are so bold as to attack the inhabitants when asleep, who hold them in the utmost detestation, and will not even kill them, lest they should be polluted by the touch. They will not even eat the bread-fruit these animals should happen to run over.

5. M. decumanus. Brown rat. Norway rat. This species is larger and stronger than the black. Its head, back, and sides, are of a light brown colour, mixed with tawny and ash-colour: its breast and belly of a dirty white: its feet are naked and of a dirty flesh colour: its fore feet are furnished with four toes, and a claw instead of a fifth. The length of its body is nine inches, of its tail the same. It weighs about eleven ounces. It inhabits most parts of Europe; but was a stranger to that continent till the present century. It came into Britain about sixty years ago. It has not been known in the neighbourhood of Paris above half that time. It is probable these animals were imported from the East-Indies, where they burrow, and undermine the foundations of houses so as to make them fall. They swarm in Petersburgh, and have reached Prussia; and sometimes migrate in vast armies, and do infinite mischief. They burrow like the water rat, on the sides of ponds, and ditches, swim well, and dive readily: live on grain and fruits, and will destroy poultry and game. They breed prodigiously fast, as they bring from fourteen to eighteen young at a time. They are very bold and fierce. When closely pursued, will turn and fasten on the hand or stick that offers to strike them.

6. M. Americanus. American rat. Larger than the black, but less than the brown rat. Its upper jaw much longer than the lower: head long: nose narrow and pointed: ears large and naked; whiskers fine, but long: tail naked, and like that of the black rat, but not so long: colour a deep brown, inclining on the belly to ash. It inhabits North America. The mus caraco is nearly allied to this species. It burrows in the banks of rivers, and is supposed to extend from the lake Baikal to China, where it is very noxious.

7. M. amphibius. Water rat. Has a thick blunt nose; ears hid in its fur; small eyes, and yellow teeth: has five toes on each foot; the inner toe of the fore foot very small, and the first joint very flexible: head and body covered with long hair, black mixed with ferruginous: belly of an iron grey: tail covered with short black hair: lip whitish: its body measures seven inches; its tail five: it bears some resemblance to the beaver: the shape of its head and body is more compact than that of the former species. It inhabits Europe, the north of Asia, and North America. Those of Canada vary to tawny and white. It burrows in the banks of rivers, ponds, and ditches; feeds on small fish and fry, frogs, insects, and roots. It swims and dives admirably; but while it preys on so many other fishes, it becomes itself the prey of the pike. It brings six young at a time. This animal, and the otter, are eaten in France on meager days.

Mus.

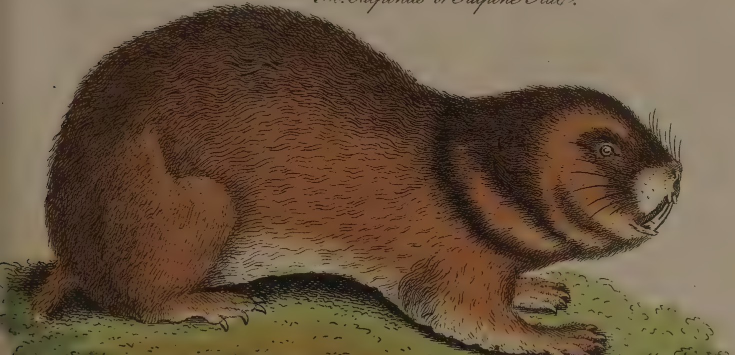


M. Soricinus or Soricine Mouse.

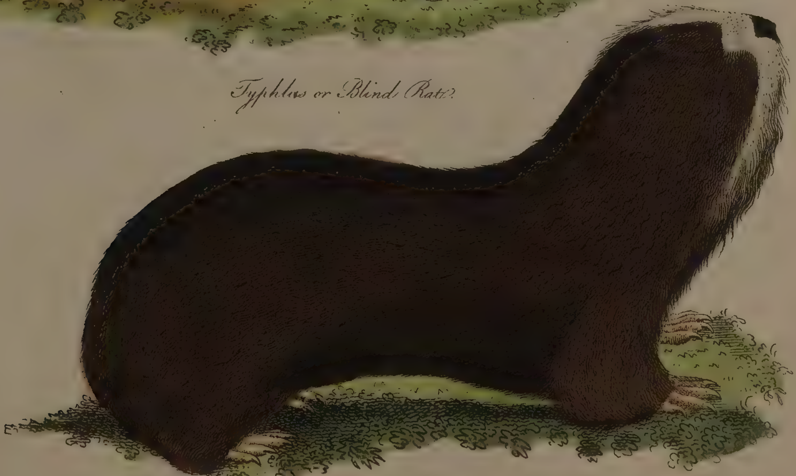
M. Lineatus or Lineated Mouse.

M. Striatus or Striated Mouse.

M. Talpinus or Talpine Rat.



Typhlus or Blind Rat.



London, Published by Sherwood & Co. Paternoster Row, May, 1st 1812.

8. M. musculus. Mouse. This species needs no description. When found white, it is very beautiful; and its full bright eye appears to great advantage amidst its snowy fur. The mouse follows mankind, and inhabits all parts of the world, except the Arctic.

9. M. silvaticus. Field-mouse. Has full black eyes: its head, back, and sides, of a yellowish brown mixed with dusky hairs: breast of an ochre colour, and belly white: its body is four inches and a half long: tail is slightly covered with hair, and measures four inches. It inhabits Europe, and is found only in fields and gardens. It feeds on nuts, acorns, and corn, and forms great magazines of provisions for winter. It makes a nest for its young very near the surface; and often in a thick tuft of grass. It brings from seven to ten young ones at a time. In some parts of England it is called the bean mouse, from the havock it makes among beans when just sown. It is common in Russia about the Uralian Chain, but not beyond.

There is an American variety of it, some white, others black, with large, naked, and open ears, and a broad dark stripe along the back. Their cheeks and sides are orange coloured: the under side of their tails is of a snowy whiteness. Their feet are white; and their hind-legs are longer than those of the European kind.

10. M. messorius. Harvest-mouse. Its eyes less prominent than those of the former species. It has prominent ears; and is of a full ferruginous colour above; white beneath; with a straight line along the sides, dividing the colours. It is two inches and a half long; its tail measures two inches. The whole animal weighs only one-sixth of an ounce.

In Hampshire, they appear in great numbers during the harvest, but never enter the houses. They are often carried into the ricks of corn in the sheaves; and are often killed in hundreds at the breaking up of the ricks. During winter they shelter themselves under ground, and burrow very deep, where they form a warm bed of dead grass. They form their nests also above ground among standing corn; and bring about eight young at a time.

11. M. striatus. Oriental mouse. About half the size of the common mouse: of a grey colour, and has rounded ears. Its back and sides are elegantly marked with twelve rows of small pearl-coloured spots, extending from the head to the rump. Its tail is as long as its body. It inhabits India. In the same country, and in Guinea, there is another small species which smells of musk. The Portuguese living in India call it cheroso, and say its bite is venomous.

12. M. Barbatus. Barbary mouse. Less than the common mouse; of a brown colour; marked on the back with ten slender streaks. It has three toes, with claws on the fore-feet, and the rudiments of a thumb. Its tail is of the same length with the body.

13. M. Mexicanus. Mexican mouse. Of a whitish colour, mixed with red. Its head is whitish: each side of its belly is marked with a great reddish spot.

14. M. Virginianus. Virginian mouse. Pointed ears; a black pointed nose; and long whiskers. Fur very short: limbs very slender: tail very thick at the base, and all beset with long hair; tapers gradually to a point; and is very long and slender. The colour of this animal is universally white. The thickness at the base of its tail is its specific difference.

15. M. vagus. Wandering mouse. This species has an oblong head, a blunt nose, with a red tip, and yellow cutting teeth. Its eyes are placed midway between the nose and ears: its ears are large, oval, and naked; but dusky and downy at the tips: its limbs are slender: its tail is longer than the body, and very slender also; its colour above is pale ash, mixed and waved with black; with a black line along the back. The ends of its limbs are whitish. Its body and tail are each about three inches long. It inhabits the whole Tartarian desert. At certain times, they wander about in great flocks, migrating from place to place during the night. They are observed in birch woods as high as 57° north. Are of a very chilly nature, soon become torpid, and sleep rolled up in a cold night, even in the month of June. They live in holes and fissures of rocks.

16. M. betulus. Birch-mouse. The birch is still less than the wandering mouse. Like it, it is very tender, and soon grows torpid in cold weather. It inhabits the same countries, runs up trees, and fastens on the boughs with its tail. By the assistance of its slender fingers, it adheres to any smooth surface. It emits a weak note: has a sharp nose, red at the point, like that of the former; but smaller ears, brown and bristly at the points. Its tail is very slender, and much longer than its body; brown above, and white below. It has a dusky line also along the back.

17. M. agrarius. Rustic mouse. This has a sharp nose, an oblong head, small ears lined with fur. Its colour is ferruginous above, whitish beneath. Above each hind-foot, it has a dusky circle. It is of a less size than the field mouse. Its tail is only half the length of its body. It is found in the temperate parts of Russia; in villages and corn fields, and in the woods of Siberia. In Russia, it is called the corn mouse. At times they migrate in vast multitudes, and destroy the whole expectations of the farmer. In 1763 and 1764, this plague made great ravages in the rich country about Casan and Arsk. They came in such numbers, as to fill the very houses; and, through hunger, became so bold as to rob the tables of bread, before the faces of those who had sat down to eat it. At the approach of winter, they all disappeared.

They burrow, and form their retreats but little below the surface.

18. M. minutus. Little mouse. The least of the genus, and weighs not half a dram. It accompanies M. agrarius in corn fields, barns, and birch woods. It is said there are more males than females of this species, and that they seem to wander without having any certain places for their nests. They have sharpish noses, and small ears, half hid in their fur, and are of a deep tawny colour above, white below, with grey feet.

19. M. saxatilis. Rock-mouse. About four inches long; tail one and a half, having a few hairs scattered over it. Head oblong: nose rather pointed: ears rise above the fur; and are oval and downy, with brown edges: whiskers short: limbs strong: colour brown, slightly mixed with grey above: belly of a light ash: snout dusky, with a very slender ring of white.

20. M. œconomus. Œconomic mouse. Small eyes: naked ears, hid in its fur; strong limbs; and very tawny teeth: colour black and yellow intimately mixed: has a dark down beneath the hair; the ends of its feet dusky: about four inches and

a quarter long: tail rather more than an inch. In the form of its body it resembles the meadow-mouse; but is rather longer, and has a bigger belly.

It inhabits all Siberia, especially its eastern parts, and Kamschatka, in great numbers. It is even found within the Arctic circle.

Professor Pallas gave these animals the name of œconomic mice, from their curious way of living. They inhabit damp soils, and shun the sandy, and form burrows with many chambers and entrances. In their chambers they lay up store of provisions, collected with great pains in summer from various plants, which they bring out of their holes in a sunny day that they may dry them more effectually. During summer they never break upon their hoards, but live on berries, and other vegetable productions. In certain years, they make great migrations out of Kamschatka. They collect in the spring, and go off in incredible multitudes. Like the lemmus, they proceed in a direct course, and neither rivers nor arms of the sea stop their progress. In their passage through the watery element, numbers of them fall a prey to ravenous fishes. But on land they are safe, for the people of Kamschatka have a superstitious veneration for them, and are so far from hurting them, that if they find any of them lying faint from fatigue or hunger, they give them all possible assistance. On their return from a migration, expresses are sent to all parts with the glad news. When the natives rob them, they never take away all their store, but leave them something to subsist on.

21. M. rutilus. Red mouse. About four inches long: its tail above one, and full of hair: its nose and face are very bristly: its back is of an uniform, pleasant, tawny red: its sides are light grey and yellow. The under side of the body whitish: feet also white: inhabits Siberia from the Oby eastward to Kamschatka, in woods and mountains. It is also found within the Arctic circle. They wander out the whole winter, and are very lively even amidst the snows. They eat any thing that comes in their way.

22. M. alliarius. Garlic mouse. Frequent in magazines of bulbous roots formed by the peasants of Siberia, especially in those of angular garlic. It has great open naked ears; its tail is clothed with hair. The colour of its back is cinereous, mixed with long hairs, tipped with a dusky grey: its sides are of a light ash: its breast, belly, and feet, are white: its body is four inches; its tail one and a half.

23. M. soricinus. Shrew-like or soricene mouse. Found in the neighbourhood of Strasbourg, of a yellowish grey on the upper parts of the body, with a white belly: nose a little extended: has four toes before, five behind, round ears, a tail of a middling length, and covered with hair.

24. M. lemmus. Lemmus, or leming. Has two very long cutting teeth in each jaw, a pointed head, and long whiskers. Its eyes are small and black: its mouth small: upper lip divided; ears small and blunt, reclining backwards: fore-legs very short, with four slender toes on each, covered with hair; and in place of a thumb, it has a short claw, like a cock's spur: has five toes behind: skin very thin: head and body black and tawny, disposed in irregular blotches: belly white, tinged with yellow: length about five inches: tail one and a half. Those of Russian Lapland are much less than those of the Norwegian or Swedish. They appear in numberless troops, at very uncertain periods, in Norway and Lapland, and are at once the pest and wonder of the country. They march like the army of locusts, so emphatically described by the prophet Joel, destroy every root of grass before them, and spread universal desolation. They infect the very ground; and cattle are said to perish which taste the grass they have touched. They march by myriads in regular lines. Nothing stops their progress; neither morass nor lake, water nor fire: the greatest rock is but a slight obstacle; they wind round it, and then go on straight. If they meet a peasant, they jump as high as his knees in defence of their progress. They are so fierce, that they will lay hold of a stick, and suffer themselves to be swung about before they quit their hold: if struck, they turn and bite, and make a noise like a dog.

They feed on grass, on the rein-deer liverwort, and the catkins of the dwarf birch. The first they get under the snow, beneath which they wander during winter. Where they make their lodgements, they have a spiracle to the surface for the sake of air. In these retreats they are eagerly pursued by the Arctic foxes.

They make also very shallow burrows under the turf; but do not form any magazines for winter provision: by this improvidence, it seems they are compelled to migrate, urged by hunger to quit their usual residence.

They breed often in the year, and bring five or six young at a time. Sometimes they bring forth on their march, during a migration: some they carry in their mouths, and others on their backs. They are not poisonous. The Laplanders often eat them, and compare their flesh to that of squirrels.

They are the prey of foxes, lynxes and ermines, who follow them in great numbers. They perish at length, either from want of food, or from their destroying each other, or in some great water, or in the sea. In former times, the priests exorcised them in a long set form of prayer. They migrate once or twice in twenty years, like a vast colony of emigrants from a country overstocked; a discharge of animals from the great northern hive, that once poured out its myriads of human creatures upon southern Europe. Where the head quarters of these quadrupeds are, is not certainly known: it was once seriously believed, that they were generated in the clouds, and that they fell in showers upon the earth; but wherever they come from, none return: their course is predestinate, and they pursue their fate.

25. M. torquatus. Ringed rat. This has a blunt nose; ears hid in its fur; legs strong and short; soles covered with hair; claws very strong, and hooked at the end, and very fine hair all over the body; of a ferruginous colour, mixed with yellow; sometimes pale grey, clouded, or waved with a dusky rust colour. From the ears, down each side of the head, there is a dusky space; and behind that, a stripe of white, so that the neck appears to be encircled with a collar; behind which there is another dusky one. The body is three inches long; the tail one. At its end there is a tuft of hard bristles. It inhabits the northern parts about the Oby; burrows with many passages beneath the turfy soil; and lines its nest with rein-deer and snow liverwort. They are said to migrate at the same seasons with the lemmus.

26. M. Hudsonius. Hudson's Bay rat. This has slender brown whiskers; very fine long soft

hair; ash, tinged with tawny, on the back, with a dusky stripe running along its middle; and along each side a pale tawny line. Its belly is of a pale ash colour: its limbs very short; fore-feet very strong. The two middle claws of the male are very strong, thick, and compressed at the end. Tail very short, terminated by some stiff bristles. Body about five inches long. It inhabits Labrador.

27. M. lagurus. Hair-tailed rat. This species has a long head, and a blunt nose; lips rough and swelling out; and ears short, round and flat: tail extremely short, scarcely appearing out of the hair: its fur is very soft and full, ash mixed with dusky, with a dark line along its back: its body is between three and four inches long. It inhabits the country about the Yaik, the Irtish, and the Jenesey. They love a firm dry soil, burrow, and make two entrances, the one oblique, the other perpendicular.

The males fight for the females, and devour each other. They are very salacious. When in heat, emit a musky smell. The females bring six at a time. Like the marmots, they are slow in their motions, and sleep rolled up like them. They are very fond of dwarf iris; but feed on all sorts of seeds. They also migrate in great troops; and the Tartars call them the rambling mouse.

28. M. socialis. Social mouse. This has a thick head; a blunt nose; naked oval ear; short strong limbs; and a slender tail. The upper part of the body of a light grey, palest on the sides: the shoulders and belly white: the body above three inches: the tail one and a half. It inhabits the Caspian desert, and the country of Hyrcania. They live in low sandy grassy places, in great societies. Their burrows are about a span deep, with eight or more passages. They are always found either in pairs, or with a family. They rarely appear in autumn; but swarm in the spring: are said to migrate, or change their place in autumn, or to conceal themselves among the bushes; and in winter to shelter themselves in hay-ricks. They breed later than the other kinds; feed much on tuli proots; and are the prey of weasels, crows, and vipers.

29. M. arvalis. Meadow mouse. Has a large head; a blunt nose; short ears hid in its fur; prominent eyes; and a short tail. The head and body ferruginous, mixed with black: belly, a deep ash colour: feet dusky: six inches long: tail one and a half, covered with hair, and tufted. It inhabits Europe. It is also found in great abundance in Newfoundland, where it does much mischief in the gardens. In England, it makes its nest in moist meadows; brings eight young at a time, and has a very great affection for them. It resides under ground, and lives on nuts, acorns, and corn.

30. M. gregalis. Gregarious mouse. Has a small mouth and blunt nose; ears naked, and appear above the fur: hair on the upper-part of its body black at the roots and tips, ferruginous in the middle; throat, belly, and feet, whitish; tail, which is one third of the length of its body, covered with thin white hairs.

It is a little larger than the common mouse, inhabits Germany and Sweden, eats sitting up, burrows and lives under ground.

31. M. cricetus. Hamster rat. This species has large rounded ears, and full black eyes; it is of a reddish brown, with red cheeks, a white spot beneath, and another behind each, and a fourth near the hind legs; its breast, the upper part of its fore-legs, and its belly black; tail short and almost naked; has four toes and a fifth claw on the fore feet, five behind; about nine inches long, tail three. The males are always bigger than the females. Some males weigh from twelve to sixteen ounces; the females seldom exceed six. They vary sometimes in colour. A family of them is frequently found about Casan entirely black. They inhabit Austria, Silesia, Poland, and the Ukraine; and as far to the east as the Jenesey. They are fond of a sandy soil abounding in liquorice, and feed on its seeds. They are very destructive to grain, eating great quantities, and carrying off still more to hoard it: on such occasions, they fill their cheek pouches, which will contain the fourth of an English pint, so full that they seem ready to burst. They live under ground, and form their burrows obliquely; at the end of the passage, the male sinks one perpendicular hole, the female several: at the end of these are formed various vaults, either as lodgings for themselves and their young, or as storehouses for their food; each young one has its different apartment, each sort of grain its different vault. Their lodgings are lined with straw or grass. Their vaults are of different depths, according to the age of the animal. A young hamster digs scarcely one foot deep: an old one four or five. The diameter of the habitation of a family, with all its communications, is from eight to ten feet. The male and female have always separate apartments; for, excepting their short season of courtship, they have no intercourse. The whole race is so malevolent, that they constantly reject all society with one another.—They will fight, kill, and devour their own species. The female brings forth two or three times in a year, from sixteen to eighteen at a birth. Their growth is very quick. At the age of three weeks, the old one forces them out, and obliges them to shift for themselves. She shews little affection for them at any time; even when they are young, in case of danger, she attemps to burrow deeper to save herself, but entirely neglects her brood: on the contrary, if attacked in the time of courtship, she defends the male with the utmost fury.

They lie torpid from the first cold to the end of winter; and during that time are seemingly quite insensible, and have the appearance of being dead. Their limbs are stiff, and their bodies cold as ice: not even spirits of wine, or oil of vitriol, poured into them, can produce the least mark of sensibility. It is only in places beyond the reach of the air that they become torpid; for the severest cold on the surface does not affect them.

The hamster, in its annual revival, begins first to lose the stiffness of its limbs, then breathes deeply, and by long intervals: on moving its limbs, it opens its mouth, and makes a rattle in its throat. It is not till after some days that it opens its eyes and attemps to stand; but even then it makes its efforts like a person very much in liquor. At length, when it has attained its usual attitude, it rests for a long time in tranquillity, seemingly to recollect itself, and recover from its fatigue.

They begin to lay in provisions of corn, peas, and beans, in August. As soon as they have finished their work, they stop up the mouth of their passage carefully. In winter the peasants go on what they call a hamster nesting; and, when they discover a horde, dig down till they reach it, and are commonly well paid; for, besides the skins of the animals, which are valuable furs, they find commonly two bushels of good grain in the magazine.

These animals are very fierce; they will jump at a horse if he happen to tread near them, and will hang by his nose in such a manner that it is difficult to disengage them. They make a noise like the barking of a dog. In some seasons so numerous as to occasion a dearth of corn, and on that account are proscribed. In Gotha, in one year, eighty thousand and upwards of their skins were presented at the Hotel de Ville. But pole-cats are their greatest enemies, for they pursue them into their holes and destroy numbers. It is remarkable, that the hair sticks so close to the skin as not to be plucked off but with the utmost difficulty.

32. M. accedula. Yaik rat. This species has a thick snout, a blunt nose, and very fleshy lips; upper lip is divided; upper fore-teeth small, yellow, convex, and truncated; lower slender and pointed; eyes large; ears naked, and stand up high above its fur; tail is short and cylindrical; face is white; body, four inches long; is of a cinereous yellow, mixed with brown above, below of a hoary whiteness. It inhabits the deserts about the Yaik, quits its burrow, and runs about during the night.

33. M. phaeus. Zarizyn rat. Forehead much elevated; the edges of its eye-lids black; ears naked and oval, standing far out of the fur; it is of a hoary ash colour, with dusky hairs above; sides whitish; the under side of the body, and the extremities of its limbs, of a snowy whiteness; about three inches and a half long, and inhabits the deserts of Astracan and the Hyrcanian mountains. About the Persian villages in Hyrcania, it commits great ravages among the rice. It does not grow torpid during the winter.

34. M. arenarius. Sand rat. Nose sharp; very large pouches, great oval brown ears, white nails, and a short hoary body: its sides, belly, limbs, and tail, of a pure white: four inches long; tail above one: inhabits and burrows in the sandy plains near the river Irtish.

35. M. songarius. Songar rat. Of a grey colour; has a thick head and a blunt nose; ears oval, very thin, and lightly covered with a hoary down; tail short, blunt, thick, and hairy. A black line runs along its back: its sides are spotted with white: its belly and legs are white. They are found in the same country with the sand rat. Dr. Pallas kept some of them a great while. They grew familiar; would feed from his hand, lap milk; and, when placed on a table, shewed no desire of running away. They were slower in all their motions than the other species; washed their faces with their paws, and sat up to eat; wandered about during the day, and slept all night rolled up. They seldom made any cry; and, when they did, it was like that of a bat.

36. M. furunculus. Baraba rat. About three inches and a quarter long, has a sharp nose, large broad naked ears of a dusky colour, edged with white. It is of a cinereous yellow above, below of a dirty white. A black line extends from the neck to near the tail: the tail, near one inch long, is white, marked with a dusky line. They inhabit the sandy plain of Baraba, towards the Oby; and about the lake Dalai, in the Chinese empire.

37. M. typhlus. Blind mole rat. This has a great head, broader than the body, and not the least aperture for eyes; yet beneath the skin are found what may be called the rudiments of those organs, though not larger than the seed of a poppy. Has no external ears: the end of its nose covered with a thick skin; nostrils remote, and placed below; mouth gapes, and the teeth are exposed; those above short; the lower ones very long, and their ends quite uneven: body cylindrical; limbs short; has five toes on each foot, with short claws: hair short, thick, and soft; dusky at the bottom, grey above, white about the mouth and nose. Between seven and eight inches long. A male will weigh above eight ounces. It inhabits the southern parts of Russia, from Poland to the Wolga. It delights in moist and turfy soils. The earth it throws up in hillocks of two yards in circumference. It works with great agility. On any apprehension of an enemy, it forms instantly a perpendicular burrow. Its bite is very severe. When irritated, it snorts and gnashes its teeth, but emits no cry. It often quits its hole, especially in the morning, and during the amorous season, along with the female, to bask in the sun. In Ukraine, the vulgar believe that the touch of a hand, which has suffocated this animal, will cure the kind's-evil.

38. M. aspalax. Daurian rat. This species has a thick flat head, a short snout, and a blunt nose. Its upper fore-teeth are naked; a moveable lip covers the lower: it has no external ears; its eyes very small, yet visible; body short and depressed; limbs very strong, especially the fore-legs; tail short, hair soft and loose, of a greyish colour. They measure from six to nine inches; inhabit the Arctic mountains, and beyond lake Baikal; burrow a little below the surface; have a voice weak and plaintive. The Russians call it the earth bear.

39. M. maritimus. African rat. This has a large head, a black nose, flat and corrugated; eyes minute, and much hid in the fur; no ears; tail about two inches long, compressed and covered above and below with short hair, and edged with bristles, disposed horizontally. Is of a cinereous brown, palest on the lower parts, and about thirteen inches long. Inhabits the sandy country near the Cape of Good Hope; burrows, and makes the ground so hollow as to be very inconvenient for travellers; for it breaks every six or seven minutes under the horse's feet, and lets them in up to the shoulders. It grows to the size of a rabbit, and is, by some, esteemed a good dish.

40. M. capensis. Cape rat. About seven inches long, and very destructive to the gardens about the Cape. Its tail is very short, beset with bristles. Though the rest of its nose is white, yet the end of it is naked and black. Its head, cheeks, back, and sides, are of a rusty brown; but it has a white space round its eyes and ears.

41. M. talpinus. Talpine rat. About four inches long, has a large short head, and a thick truncated snout. Upper teeth long and flat, extending out of its mouth: eyes small, hid in its fur; ears bounded by a small rim; tail scarce appears without the fur; upper parts dusky; chin, belly, and limbs, whitish. It inhabits the open grounds of the temperate parts of Russia and Siberia: loves a black turfy soil, and is frequent in meadows near villages. Its manners resemble those of the mole. These rats do not become torpid in the winter; but make their nest deep in the ground, and keep themselves warm by lining it with soft grass. They are very easily taken, but soon grow sick in confinement, unless a quantity of earth is put into the place where they are kept. They are in heat in the end of March or beginning of April; the females have then a strong musky smell: they bring three or

four at a time. They vary in colour; some are found quite black. See Nat. Hist. Pl. CLVIII.

MUSA, in botany, a genus of the class polygamia, order monœcia. Herm. Spathe partial, many-flowered; corol two-petalled; one of them erect, five-toothed; the other nectariferous, concave and shorter; stamens six; style one. Male above: five filaments, perfect; germ inferior, abortive. Fem. one filament, perfect; berry inferior, oblong, three-sided, many-seeded. Three species, as follow:

1. M. paradisiaca. Plaintain-tree. Spadix nodding; males permanent. It grows spontaneously in many parts of India, but has been immemorially cultivated by the Indians in every part of the continent of South America. It is an herbaceous tree, growing to the height of fifteen or twenty feet. The pomes are nearly of the size and shape of ordinary cucumbers, and when ripe of a pale yellow colour, of a mealy substance, a little clammy, a sweetish taste, and will dissolve in the mouth without chewing. The whole spike of fruit often weighs forty or fifty pounds. When they are brought to table by way of desert, they are either raw, fried, or roasted; but if intended for bread, they are cut before they are ripe, and are then either roasted or boiled. The trees being tall and slender, the Indians cut them down to get at the fruit; and in doing this they suffer no loss, for the stems are only one year's growth, and would die if not cut; but the roots continue, and new stems soon spring up, which in a year produce ripe fruit also. From the ripe plaintains they make a liquor called mistaw. When they make this, they roast the pomes in their husks, and after totally beating them to a mash, they pour water upon them, and as the liquor is wanted it is drawn off. But the nature of this fruit is such, that it will not keep long without running into a state of putrefaction; and therefore, in order to reap the advantage of it at all times, they make cakes of the pulp, and dry them over a slow fire, and as they stand in need of mistaw, they mash the cakes in water, and they answer all the purposes of fresh fruit. These cakes are exceedingly convenient to make this liquor in their journeys, and they never fail to carry them for that purpose. The leaves of the tree being large and spacious, serve the Indians for tablecloths and napkins. These leaves are nevertheless thin and tender; so that when they are exposed to the open air they are generally torn by the wind; for in consequence of their extent, the wind has the greater power against them. They are deeply seated in their origin, and seem to proceed from the very center of the stalk; they at first appear to be rolled up, but as they advance above the stalk they expand and turn backward.

In Jamaica this tree is so largely cultivated, and found so truly useful, that according to some writers the island could not subsist without it.

Wheaten flower is said to be less palatable and even less wholesome to the laborious negro than the food afforded by this plant. It also serves to fatten horses, oxen, swine, dogs, poultry, and other domestic animals.

2. M. sapientum. Banana tree. Spadix nodding; males deciduous. Stalks marked with dark purple stripes or spots; fruit shorter and rounder, with a softer pulp of a still more delicious taste. It is never eaten green; but is very agreeable when ripe; is extremely agreeable, and relished by all ranks of people, either eaten raw, or fried in slices or fritters. It is supposed to be a native of Guinea, and carried thence to the West India islands, where it flourishes most abundantly. It is also cultivated in Egypt and in other hot countries, where it grows to perfection in about ten months from first planting to the ripening of the fruit. When the stalks are cut down several suckers rise from the roots, which in six or eight months produce fruit; so that by cutting down the stalks at different times, a constant succession of fruit may be obtained through the whole year.

They may be made to grow in our own hot-houses when they are very large, but it is not often that we meet with sufficient space for their accommodation. They may be propagated by suckers that shoot from the roots of plants that have fruited. The fruit is about four or five inches long, of the form of the cucumber. The leaves are two yards long, and a foot broad in the middle; they join to the top of the body of the tree, and often contain in their cavities a great quantity of water, which runs out upon a small incision being made into the tree, at the junction of the leaves. The weight of a bunch of bananas usually exceeds 12lb. The trunk of the tree is peculiarly porous; the roots alone are perennial, the rest dying down to the ground every autumn.

3. M. troglodytarum. Spadix erect; spathe deciduous. The spathe and berry are both scarlet, but the latter is not eatable. It is a native of the Molucca Islands.

MUSÆUS, an ancient Greek poet, was, according to Plato and Diodorus Siculus, an Athenian, the son of Orpheus, and chief of the Eleusinian mysteries instituted at Athens in honour of Ceres: or, according to others, he was only the disciple of Orpheus: but from the great resemblance which there was between his character and talents and those of his master, by giving a stronger outline to the figure he was called his son, as those were styled the children of Apollo who cultivated the arts of which he was the tutelar god.

Musæus is allowed to have been one of the first poets who versified the oracles. He is placed in the Arundelian marbles, epoch 15. 1426 B. C. at which time his hymns are there said to have been received in the celebration of the Eleusinian mysteries. Laertius tells us, that Musæus not only composed a theogony, but formed a sphere for the use of his companions; yet as this honour is generally given to Chiron, it is more natural to suppose, with sir Isaac Newton, that he enlarged it with the addition of several constellations after the conquest of the golden fleece. The sphere itself shows that it was delineated after the Argonautic expedition, which is described in the asterisms, together with several other more ancient histories of the Greeks, and without any thing later; for the ship Argo was the first long vessel which they had built: hitherto they had used round ships of burthen, and kept within sight of the shore; but now, by the dictates of the oracle, and consent of the princes of Greece, the flower of that country sail rapidly through the deep, and guide their ship by the stars.

Musæus is celebrated by Virgil in the character of hierophant, or priest of Ceres, at the head of the most illustrious mortals who have merited a place in Elysium. Here he is made the conductor of Æneas to the recess where he meets the shade of his father Anchisés.

A hill near the citadel of Athens was called Musæum, according to Pausanias, from Musæus, who used to retire thither to meditate and compose his religious hymns; at which place he was afterwards buried. The works which went under his name, like those of Orpheus, were by many attributed to Onomacritus. Nothing remains of this poet now, nor were any of his writings extant in the time of Pausanias, except a hymn to Ceres, which he made for the Lycomides.

MUSARS. The name given to certain itinerant musicians who performed on the musette, and were formerly very numerous in most countries of Europe. See MUSETTE.

MUSCA. Fly. In zoology, a genus of the class insecta, order diptera. Mouth with a soft exserted fleshy proboscis, and two equal lips; sucker furnished with bristles; two very short feelers or none; antennas generally short. Five hundred and twenty known species scattered over the globe, of which a hundred are common to our own country. They may be thus subdivided.

A. With two short feelers.

α. Sucker with a single bristle without sheath; antennas short, clavate, furnished with a lateral line: the hair of the antennas in the greater number feathered; in the rest naked. This section embraces nearly two thirds of the entire genus.

ϐ. Sucker with a single bristle, without sheath: antennas pointed and united at the base. This section constitutes the stratiomys of Fabricius.

γ. Sucker with a single bristle and univalve sheath; antennas seated on a common petiole. It constitutes the ceria of Fabricius, and embraces only a single species: it inhabits Kiel and Barbary.

δ. Sucker with three bristles, without sheath; feelers placed at the base of the sucker. The rhagis tribe of Fabricius.

ε. Sucker with three bristles and a single-valved sheath; antennas united at the base and pointed at the tip. The bibio tribe of Fabricius.

ϛ. Sucker with four bristles, without sheath; feelers placed at the base of the bristle. The antennas of some of these are feathered, but of the greater number naked. It is a numerous tribe, and forms the syrphus of Fabricius.

B. Feelerless.

α. Sucker with a single recurved bristle without sheath; antennas inserted at the base of the proboscis. This tribe forms the nemotilus of Fabricius, and includes only seven species.

ϐ. Sucker with a single bristle without sheath; antennas approximate, with an ovate compressed club. It includes only four species, and forms the mydas of Fabricius.

It is probable that the known species bear no comparison to the unknown. Mr. Harris, in his English entomology, describes a greater number of species than Linnéus enumerated as existing in the world: yet England is far from being a country most productive of this insect. The south of Europe affords a much greater variety of species than the north; and all hot climates than cold. In hot climates, indeed, they multiply to a degree almost intolerable, and are incalculably mischievous both to animal and vegetable foods.

The different species are extremely diversified in their external form, their structure, their organization, their metamorphosis, their manner of propagating their species, and in providing for their posterity. A full explanation of these different parts of their economy would require a large volume, and would constitute a narrative to many readers not uninteresting. Such an undertaking, however, is incompatible with the limits prescribed to our work.

Some of these insects have trunks instead of a mouth; others have that organ armed with teeth; and many have both a mouth and a trunk. The proboscis of flies is a machine contrived for pumping the blood from the vessels of large animals, and the nectar from the petals of flowers; and the science of hydraulics has not enabled men to construct machines more complicated, more exactly arranged, or better adapted to these purposes. Some of them possess considerable firmness and solidity, those especially that are destined to pierce the skins of cattle. In order to see them at work, all that is necessary is to expose a syrup to attract them, and to take up a lens for their inspection.

Each eye of the fly contains in it an assemblage of a great number of small ones, which according to Reaumur has the effect of multiplying the surrounding objects, and creating representations of them, which the experience of the insect corrects. From the eye, if you pass along and survey the body, you find it provided with the organs of respiration. Four small stigmata, for this purpose, are found upon the thorax, and a greater number dispersed over the annuli of the abdomen. The covering of the different parts of the abdomen are scaly, and do not consist all of one piece, but admit of the contraction and dilatation of that part, according to the circumstances of the animal. Each of the feet terminates in a small bunch of setæ resembling a brush.

The interior organization of this genus, when examined with a proper apparatus, presents two pulmonary sacs of a white colour, arranged longitudinally along the body. As the bodies of some species are diaphanous, the action of the heart may also be discerned, as well as the liquor it contains, continually driven along the great artery leading to it, and returning by the same course. During their larve state, flies in general go through a greater variety of metamorphoses than even the silk or butterfly worms: in their progress from the vermicular to the chrysalis state, they pass through an intermediate change, unexperienced by other insects. From the shortness of their lives, all these vicissitudes must rapidly succeed each other: this circumstance, however, does not prevent many species from constructing a cocoon for their last metamorphosis, of a curious fabric. The greater part of these cocoons are of silk, with a mixture of other materials; those, indeed, most common with us serve themselves with their own skin, which becomes an incrustated covering to protect them during their dormant and aurelia state.

When the different members have acquired sufficient firmness, the fly is ready to burst from its shell in its winged form. The covering of the chrysalis, especially of those that are metamorphosed in their own skin, would seem to prove, by its hardness, an effectual bar to that event. About the time, however, of its change, the head of the fly is capable of being swollen and dilated in an unusual manner; and it is by means of this dilatation that the fly bursts its covering, and opens a passage for its escape.

The food of flies is as various as their different kinds; some being supported wholly by vegetable substances, while others are carnivorous; and among the latter there are some that only devour flesh in a state of putrefaction. Dung, and vegetables in a similar state, are the favourite meals of others.

The female flies are all fecundated by copulation; an act in which the most incurious observer must have frequently seen them engaged. The observations of Reaumur seem to prove, that the females of some kinds take that part in the act of fecundation which is usually performed by the male in other animals; and that it is her extremity which penetrates into the body of the male. The far greater part of insects are oviparous; some, however, belonging to this genus bring forth living young: but what appears most unaccountable is, that some apparently of the same species are viviparous, while the rest lay eggs; a circumstance that shews the futility of our attempts to arrange them. Many of the viviparous flies possess a degree of fecundity that must appear altogether incredible to those who have not been versant in the study of insects. Some of them have been found to contain in their body no less than twenty thousand living animals at one time. We shall notice a few species.

1. M. domestica. House fly. The thorax of this species is brown, having upon it four occult dark lines; the abdomen is of an orange brown, with a few spots of black. This fly seldom makes its appearance before the month of July.

2. M. vespæ similis. Wasp fly. Entirely resembles the animal whose name it bears: the head is lemon coloured; the antennas brown, the thorax and abdomen black, the latter marked with transverse bands of yellow.

3. M. pellucens. Transparent fly. Thorax black, partially covered with a few brown hairs, and having the point sometimes yellow: abdomen with black beneath, white above; transparent both below and above.

4. M. carnaria. Flesh fly. Hairy, black; thorax with paler lines; abdomen shining, tesselate. Inhabits Europe on putrid meat, on which it deposits its whitish, oblong eggs most readily, though often likewise on fresh meat. The larves or maggots hatch in the space of a few hours, become full grown in eight or ten days, and are then of a whitish or yellowish-white colour with a slight tinge of pale red, shape long, with a sharpened front in which the mouth is situated, and whence the body gradually enlarges in size to the last or terminal segment, which is of a broad and flattened form, surrounded by several slightly prominent tips, and furnished with a pair of dusky specks resembling eyes: so that an inaccurate spectator may easily mistake this part for the head, and the proper head for the tail. When the larve changes to a chrysalis the skin dries around it, and the whole assumes a completely oval form, and a reddish colour. In ten days more the fly itself emerges and becomes perfect.

5. M. flava. Yellow, with bright gold-green eyes. One of the smallest but most elegant of the European tribes.

6. M. vomitoria. Blow-fly. Thorax black; abdomen shining, blue; front fulvous.

This is also a fly that frequents putrid meat, and deposits a larve of a similar appearance, and hatched in the same manner as that of M. carnaria.

7. M. chamæleon. Scutel two-toothed, yellow; abdomen black, with three triangular yellow spots on each side, and one at the end. Inhabits England and Europe generally near fresh waters; the front of the male yellow, of the female cinereous. The eggs are deposited in the hollow stalks of aquatic plants or broken reeds. The larve has twelve annular divisions, its tail a circular fringe of hairs, which when expanded support it on the surface of the water with the head downwards.

MU'SCADEL. MUSCADINE. *a.* (*muscal*, *muscadel*, Fr. *moscatello*, Ital.) A kind of sweet grape, sweet wine, and sweet pear.

MUSCHENBROECK (Peter de), a very distinguished natural philosopher and mathematician, was born at Utrecht a little before 1700. He was first professor of these in his own university, and afterwards invited to the chair at Leyden, where he died full of reputation and honours in 1761. He was a member of several academies; particularly the academy of sciences at Paris. He was the author of several works in latin, all of which show the greatest penetration and exactness in this way. He was also very consummate in the knowledge of law. His Elements of Natural Philosophy were translated into the English language by Professor Colson of Cambridge, and published in 1744, in two volumes 8vo.

MUSCI. Mosses. The third of the families, and the seventh of the nations or casts, into which Linnéus has distributed all vegetables.—The sixty-fifth order in his Fragments; and the fifty-sixth of his Ordines Naturales.—They form the second order of the class cryptogamia, in his artificial system.

Hedwig has made considerable discoveries with respect to the fructification of mosses.

MUSCICAPA. Fly-catcher. In zoology, a genus of the class aves, order passeres. Bill nearly triangular, notched on each side, bent in at the tip, and beset with bristles at the root: toes (mostly) divided to their origin. Ninety-six species, scattered over the warmer tracts of the globe, two only common to our own country: the greater number inhabitants of Australasia and Polynesia. Among ourselves the fly-catcher is a bird of passage that breeds in the island, but retires as early as the month of August. It builds its nest upon the sides of trees, or of old walls, and feeds upon insects. When the young are led out, they generally take their station upon the higher boughs of trees, whence they are taught to drop perpendicularly upon the flies below, and to rise again in the same manner. Subordinate to the rapacious birds, and in the next class, nature has placed this tribe of hunters, more numerous than that of its superiors, because more useful. The largest of this genus is of the size of the butcher bird, while the smallest is not larger than the nightingale. All the intermediate degrees are occupied by various kinds, differing in magnitude, but marked by the same generic characters.

The following are the species mostly worthy of notice.

1. M. aédon. Rusty-brown, beneath yellowish white; middle tail-feathers subequal, the outermost on each side much shorter. Inhabits Dauria: size of turdus arundinaceus; and sings delightfully during the night.

2. M. grisola. Spotted fly-catcher. Brownish, beneath whitish; neck longitudinally spotted; vent pale rufous, back mouse-colour; wings and tail black, the former edged with white; chin spotted with red; legs black. Inhabits England and Europe at large: five and a half inches long; appears in England in the spring, and retires in August; builds in holes of walls or hollow trees; is fond of cherries; eggs pale, spotted with reddish.

3. M. rubicollis. Purple-throated fly-catcher. Black; chin and throat with a large purple-red spot. Inhabits the woods of South America; twelve inches long; is gregarious; feeds on fruits and insects, and often associates with the toucan.

4. M. flabellifera. Fan-tailed fly-catcher. Above olive, beneath ferruginous; eyebrows, chin, throat, sides of the neck, and lateral tail-feathers white; middle tail feathers, head, and collar black; bill black. Inhabits New Zealand; six and a half inches long; flies with its tail expanded like a fan; is easily tamed, and will sit on the shoulders and pick off flies as they appear.

5. M. Carolinensis. Cat fly-catcher. Brown, beneath cinereous: head black, vent red; bill and crown black; tail even, blackish. Inhabits Virginia: eight inches long; mews like a cat.

MUSCLE. *Musculus.* In anatomy, the parts that are usually included under this name consist of distinct portions of flesh, susceptible of contraction and relaxation; the motions of which, in a natural and healthy state, are subject to the will, and for this reason they are called voluntary muscles. Besides these, there are other parts of the body that owe their power of contraction to their muscular fibres, independently of the will: thus the heart is a muscular texture, forming what is called a hollow muscle; and the urinary bladder, stomach, intestines, &c. are enabled to act upon their contents, merely because they are provided with muscular fibres; these are called involuntary muscles, because their motions are not dependent on the will. The muscles of respiration being in some measure influenced by the will, are said to have a mixed motion. The names by which the voluntary muscles are distinguished are founded on their size, figure, situation, use, or the arrangement of their fibres, or their origin and insertion; but besides these particular distinctions, there are certain general ones that require to be noticed. Thus, if the fibres of a muscle are placed parallel to each other, in a straight direction, they form what anatomists term a rectilinear muscle; if the fibres cross and intersect each other, they constitute a compound muscle; when the fibres are disposed in the manner of rays, a radiated muscle; and when they are placed obliquely with respect to the tendon, like the plume of a pen, a penniform muscle. Muscles that act in opposition to each other are called antagonists; thus every extensor has a flexor for its antagonist, and *vice versa.* Muscles that concur in the same action are termed congeneres. The muscles being attached to the bones, the latter may be considered as levers, that are moved in different directions by the contraction of those organs. That end of the muscle which adheres to the most fixed part is usually called the origin; and that which adheres to the more moveable part the insertion of the muscle. In almost every muscle two kinds of fibres are distinguished; the one soft, of a red colour, sensible, and irritable, called fleshy fibres, see MUSCULAR FIBRES; the other of a firmer texture, of a white glistening colour, insensible, without irritability or the power of contracting, and named tendinous fibres. They are occasionally intermixed, but the fleshy fibres generally prevail in the belly, or middle part of the muscle, and the tendinous ones in the extremities. If these tendinous fibres are formed into a round slender cord, they form what is called the tendon of the muscle; on the other hand, if they are spread into a broad flat surface, it is termed an aponeurosis.

Each muscle is surrounded by a very thin and delicate covering of cellular membrane, which incloses as it were like a sheath, and dipping down into its substance, surrounds the most minute fibres we are able to trace, connecting them to each other, lubricating them by means of the fat which its cells contain in more or less quantity in different subjects, and serving as a support to the blood-vessels, lymphatics, and nerves, which are so plentifully distributed through the muscles.—This cellular membrane, which in no respect differs from that is found investing and connecting the other parts of the body, has been sometimes mistaken for a membrane peculiar to the muscles; and hence we often find writers giving it the name of membrana propria musculosa. The muscles owe the red colour which so particularly distinguishes their belly part to an infinite number of arteries, which are every where dispersed through the whole of their reticular substance; for their fibres, after having been macerated in water, are, (like all other parts of the body divested of their blood), found to be of a white colour. These arteries usually enter the muscles by several considerable branches, and ramify so minutely through their substance, that we are unable, even with the best microscopes, to trace their ultimate branches. Ruysch fancied that the muscular fibre was hollow, and a production of a capillary artery; but this was merely conjectural. The veins, for the most part, accompany the arteries, but are found to be larger and more numerous. The lymphatics, likewise, are numerous, as might be expected from the great proportion of reticular substance, which is every where found investigating the muscular fibres. The nerves are distributed in such abundance to every muscle, that the muscles of the thumb alone are supplied with a greater proportion of nervous influence than the largest viscera, as the liver for instance. They enter the generality of muscles by several trunks, the branches of which, like those of the blood-vessels, are so minutely dispersed through the cellular substance, that their number and minuteness soon elude the eye and the knife of the anatomist. This has given rise to a conjecture, as groundless as all the other conjectures on this subject, that the muscular fibre is ultimately nervous.

Table of the Muscles.—The generality of anatomical writers have arranged muscles according to their several uses; but this method is evidently defective, as the same muscle may very often have different and opposite uses. The method here adopted is that more usually followed; they are enumerated in the order in which they are situated, beginning with those that are placed nearest the integuments, and proceeding from these arranged in successive order from the head to the feet, those not in pairs being distinguished by the mark*.

Muscles of the integuments of the cranium:

Occipito frontalis *. Corrugator supercilii.

Muscles of the eye-lids:

Orbicularis palpebrarum. Levator palpebræ superioris.

Muscles of the eye-ball:

Rectus superior. Rectus inferior. Rectus internus. Rectus externus. Obliquus superior. Obliquus inferior.

Muscles of the nose and mouth:

Levator palpebræ superioris alæque nasi. Levator labii superioris propius. Levator anguli oris. Zygomaticus major. Zygomaticus minor. Buccinator. Depressor anguli oris. Depressor labii inferioris. Orbicularis oris *. Depressor labii superioris alæque nasi. Constrictor nasi. Levator menti vel labii inferioris.

Muscles of the external ear:

Superior auris. Anterior auris. Posterior auris. Helicis major. Helicis minor. Tragicus. Antitragicus. Transversus auris.

Muscles of the internal ear:

Laxator tympani. Membrana tympani. Tensor tympani. Stapedius.

Muscles of the lower jaw:

Temporalis. Masseter. Pterygoideus externus Pterygoideus internus.

Muscles about the anterior part of the neck:

Platysma myoides. Sterno-cleido-mastoideus.

Muscles between the lower jaw and os hyoides:

Digastricus. Mylo-hyoideus. Genio-hyoideus. Genio-glossus. Hyo-glossus. Lingualis.

Muscles situated between the os hyoides and trunk:

Sterno-hyoideus. Crico-hyoideus. Sterno-thyroideus. Thyreo-hyoideus. Crico-thyroideus.

Muscles between the lower jaw and os hyoides laterally:

Stylo-glossus. Stylo-hyoideus. Stylo-pharyngeus. Circumflexus. Levator palati mollis.

Muscles about the entry of the fauces:

Constrictor isthmi faucium. Palato-pharyngeus. Azygos uvulæ*.

Muscles situated on the posterior part of the pharynx:

Constrictor pharyngis superior. Constrictor pharyngis medius. Constrictor pharyngis inferior.

Muscles situated about the glottis:

Crico-arytænoideus posticus. Crico-arytænoideus lateralis. Thyreo-arytænoideus. Arytænoideus obliquus*. Arytænoideus transversus*. Thyreo-epiglottideus. Arytæno-epiglottideus.

Muscles situated about the anterior part of the abdomen:

Obliquus descendens externus. Obliquus ascendens internus. Transversalis abdominis. Rectus abdominis. Pyramidalis.

Muscles about the male organs of generation:

Cremaster. Erector penis. Accelerator urinæ. Transversus perinei.

Muscles of the anus:

Sphincter ani *. Levator ani *.

Muscles of the female organs of generation:

Erector clitoridis. Sphincter vaginæ *.

Muscles situated within the pelvis:

Obturator internus. Coccygeus.

Muscles situated within the cavity of the abdomen:

Diaphragma *. Quadratus lumborum. Psoas parvus. Psoas magnus. Iliacus internus.

Muscles situated on the anterior part of the thorax:

Pectoralis major. Subclavius. Pectoralis minor. Serratus major anticus.

Muscles situated between the ribs, and within the thorax:

Intercostales externi. Intercostales interni. Triangularis.

Muscles situated on the anterior part of the neck, close to the vertebræ:

Longus colli. Rectus internus capitis major. Rectns capitis internus minor. Rectus capitis lateralis.

Muscles situated on the posterior part of the trunk:

Trapezius. Latissimus dorsi. Serratus posticus inferior. Rhomboideus. Splenius. Serratus superior posticus. Spinalis dorsi. Levatores costarum. Sacro-lumbalis. Longissimus dorsi. Complexus. Trachelo-mastoideus. Levator scapulæ. Semi-spinalis dorsi. Multifidus spinæ. Semi-spinalis colli. Transversalis colli. Rectus capitis posticus minor. Obliquus capitis superior. Obliquus capitis in ferior. Scalenus. Interspinales. Intertransversales.

Muscles of the superior extremities:

Supra-spinatus. Infra spinatus. Teres minor. Teres major. Deltoides. Coraco-brachialis. Subscapularis.

Muscles situated on the os humeri:

Biceps flexor cubiti. Brachialis internus. Biceps extensor cubiti. Anconeus.

Muscles situated on the fore arm:

Supinator radii longus. Extensor carpi radialis longior. Extensor carpi radialis brevior. Extensor digitorum communis. Extensor minimi digiti. Extensor carpi ulnaris. Flexor carpi ulnaris. Palmaris longus. Flexor carpi radialis. Pronator radii teres. Supinator radii brevis. Extensor ossis metacarpi pollicis manus. Extensor primi internodii. Extensor secundi internodii. Indicator. Flexor digitorum sublimis. Flexor digitorum profundus. Flexor longus pollicis. Pronator radii quadratus.

Muscles situated chiefly on the hand:

Lumbricales. Flexor brevis pollicis manus. Adductor pollicis manus. Abductor indicis manus. Opponens pollicis. Abductor pollicis manus. Palmaris brevis. Abductor minimi digiti manus. Adductor minimi digiti. Flexor parvus minimi digiti. Interossei interni. Interossei externi.

Muscles of the inferior extremities:

Pectinalis. Triceps adductor femoris. Obturator externus. Gluteus maximus. Gluteus minimus. Gluteus medius. Pyriformis. Gemini. Quadratus femoris.

Muscles situated on the thigh:

Tensor vaginæ femoris. Sartorius. Rectus femoris. Vastus externus. Vastus internus. Cruralis. Semi-tendinosus. Semi-membranosus. Biceps flexor cruris. Popliteus.

Muscles situated on the leg:

Gastrocnemius externus. Gastrocnemius internus. Plantaris. Tibialis anticus. Tibialis posticus. Peroneus longus. Peroneus brevis. Extensor longus digitorum pedis. Extensor proprius pollicis pedis. Flexor longus digitorum pedis. Flexor longus pollicis pedis.

Muscles chiefly situated on the foot:

Extensor brevis digitorum pedis. Flexor brevis digitorum pedis. Lumbricales pedis. Flexor brevis pollicis pedis. Abductor pollicis pedis. Adductor pollicis pedis. Abductor minimi digiti pedis. Flexor brevis minimi digiti pedis. Transversales pedis. Interossei pedis externi. Interossei pedis interni

For their origins, insertions, and uses, see ANATOMY.

MUSCLE, in zoology. See MYTILUS.

MUSCO'SITY. *s.* (*muscosus*, Lat.) Mossiness.

MUSCOVY. See RUSSIA.

MUSCOVY GLASS. See MICA.

MU'SCULAR. *a.* (from *musculus*, Lat.) Relating to muscles; performed by muscles.

MUSCULAR FIBRE, that part of the body of an animal which, in common language is known by the name of flesh, and constitutes a considerable portion of the food of man, and of various other mammalian tribes: for the chemical properties of which see, the article FLESH.

The fibres that compose the body of a muscle are arranged in fascicles or bundles, which are easily distinguishable by the naked eye; but these fascicles are divisible into still smaller ones; and these again are probably subdivisible almost *ad infinitum*. The most minute fibre we are able to trace, seems to be somewhat plaited: these plaits disappearing when the fibre is put upon the stretch, appear evidently to be the effect of contraction, and have probably induced some writers to assert, that the muscular fibre is twisted or spiral. Various have been the opinions concerning the structure of these fibres; they are all of them founded only on conjecture, and therefore we shall mention only the principal ones, and this with a view rather to gratify the curiosity of the reader, than to afford him information. Borelli supposes them to be so many hollow cylinders, filled with a spongy medullary substance, which he compares to the pith of elder, *spongiosa ad instar sambuci*. These cylinders, he contends, are intersected by circular fibres, which form a chain of very minute bladders. This hypothesis has since been adopted by a great number of writers, with certain variations. Thus, for instance, Borelli supposes the vesicles to be of a rhomboidal shape; whereas Bernouilli contends that they are oval. Cowper went so far as to persuade himself that he had filled these cells with mercury; a mistake, no doubt, which arose from its insinuating itself into some of the lymphatics. It is observable, however, that Leeuwenhoeck says nothing of any such vesicles. Here, as well as in many other of her works, nature seems to have drawn a boundary to our inquiries, beyond which no human penetration will probably ever extend. It is surely more commendable, however, to acknowledge our ignorance, than to indulge ourselves in chimæra.

MUSCULAR MOTION. Muscular motions are of three kinds; namely, voluntary, involuntary, and mixed. The voluntary motions of muscles are such as proceed from an immediate exertion of the active powers of the will: thus, the mind directs the arm to be raised or depressed, the knee to be bent, the tongue to move, &c. The involuntary motions of muscles are those which are performed by organs, seemingly of their own accord, without any attention of the mind, or consciousness of its active power: as the contraction and dilatation of the heart, arteries, veins, absorbents, stomach, intestines, &c. The mixed motions are those which are in part under the controul of the will, but which ordinarily act without our being conscious of their acting; as is perceived in the muscles of respiration, the intercostals, the abdominal muscles, and the diaphragm.

When a muscle acts, it becomes shorter and thicker; both its origin and insertion are drawn towards its middle. The sphincter muscles are always in action; and so likewise are antagonist muscles, even when they seem at rest. When two antagonist muscles move with equal force, the part which they are designed to move remains at rest; but if one of the antagonist muscles remains at rest; while the other acts, the part is moved towards the centre of motion.

All the muscles of living animals are constantly endeavouring to shorten themselves.

When a muscle is divided it contracts. If a muscle be stretched to a certain extent, it contracts, and endeavours to acquire its former dimensions, as soon as the stretching cause is removed: this takes place in the dead body; in muscles cut out of the body, and also in parts not muscular, and is called by the immortal Haller *vis mortua*, and by some *vis elastica*. It is greater in living than in dead bodies, and is called the tone of the muscles.

When a muscle is wounded, touched, or otherwise irritated, it contracts independent of the will: this power is called irritability, and by Haller *vis insita*; it is a property among animals peculiar to and inherent in the muscles. The parts of our body which possess this property are called irritable, as the heart, arteries, proper muscles, &c. to distinguish them from those parts which have no muscular fibres. With regard to the degree of this property peculiar to various parts, the heart is the most irritable, then the stomach and intestines; the diaphragm, the arteries, veins, absorbents, and at length the various proper muscles follow; but the degree of irritability depends upon the age, sex, temperament, mode of living, climate, state of health, idiosyncrasy, and likewise upon the nature of the stimulus.

When a muscle is stimulated, either through the medium of the will or any foreign body, it contracts, and its contraction is greater or less in proportion as the stimulus applied is greater or less. The contraction of muscles is different according to the purpose to be served by their contraction: thus, the heart contracts with a jerk; the urinary bladder, slowly and uniformly; puncture a muscle, and its fibres vibrate; and the abdominal muscles act slowly in expelling the contents of the rectum. Relaxation generally succeeds the contraction of muscles, and alternates with it.

The use of this property is very considerable; for upon it depends all muscular motion, and the function of every viscus, except that of the nerves.

Upon the various theories that have been advanced to explain the cause of muscular power or irritability we have dwelt at some length in the article IRRITABILITY; and to that we refer the reader on the present occasion. We have only to add that in a very elaborate paper on the function of the heart and arteries, written by Dr. Young, and inserted, as the Croonian lecture, in the Philosophical Transactions for 1809, this acute reasoner has attempted to establish in a considerable degree the circulation of the blood upon the general laws of hydraulics, and to prove that in the ordinary circulation the fibres of the muscular tunic of the arteries have very little effect in propelling the blood, their use being almost limited to accommodating the blood-vessels to their contents, by altering the capacity of the canal.

MUSCULA'RITY. *s.* (from *muscular.*) The state of having muscles (*Grew*).

MU'SCULOUS. *a.* (*musculosus*, Lat.) 1. Full of muscles; brawny. 2. Pertaining to a muscle (*More*).

MUSCULUS. (*musculus*, of *mus*, a mouse, from its resemblance to a flead mouse.) See MUSCLE.

MUSCULUS CUTANEUS. See PLATYSMA MYOIDES.

MUSCULUS PATIENTIÆ See LEVATOR SCAPULÆ.

MUSCULUS TUBÆ NOVÆ. See CIRCUMFLEXUS.

MUSCUS ARBOREUS. This plant, lichen plicatus of Linnéus, we are informed by that great botanist, is applied by the Laplanders to parts which are excoriated by a long journey. It is slightly adstringent, and is applied with that intention to bleeding vessels.

MUSCUS CANINUS. See LICHEN CINEREUS TERRESTRIS.

MUSCUS CLAVATUS. See LYCOPODIUM.

MUSCUS CRANII HUMANI. See USNEA.

MUSCUS CUMATILIS. This cryptogamious plant, lichen apthosus, is said to act powerfully on the intestines, though never used in the practice of the present day.

MUSCUS ERECTUS. Upright club moss. The pharmacopœial name of the lycopodium selago of Linnéus. The decoction of this plant acts violently as a vomit and a purgative, and was formerly on that account employed to produce abortions.

MUSCUS ISLANDICUS. See LICHEN ISLANDICUS.

MUSCUS MARITIMUS. See CORALLINUS.

MUSCUS PULMONARIUS QUERCINUS. See PULMONARIA ARBOREA.

MUSCUS PYXIDATUS. Cup moss. These very common little plants, lichen cocciferus, and pyxidatus of Linnéus, for both are used indifferently, are employed by the common people in this country in the cure of hooping cough.

To **MUSE.** *v. n.* (*muser*, French.) 1. To ponder; to think close; to study in silence (*Hooker*). 2. To be absent of mind; to be attentive to something not present (*Shakspeare*). 3. To wonder; to be amazed (*Shakspeare*).

MUSEIA, were Grecian festivals in honour of the muses, celebrated with games every fifth year, particularly by the Thespians. The Macedonians also observed a festival of the same name in honour of Jupiter and the muses, which lasted for nine days, and was celebrated with stage plays, songs, and poetical compositions.

MUSES, certain fabulous deities among the pagans, supposed to preside over the arts and sciences: for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid. The muses were originally only singers and musicians in the service of Osiris, or the great Egyptian Bacchus, under the instruction and guidance of his son Orus; but in succeeding times they were called the daughters of Jupiter and Mnemosyne or Memory.

These are the only pagan divinities whose worship has been continued through all succeeding changes in the religion and sentiments of mankind. Professors of every liberal art in all the countries of Europe still revere them; particularly the poets, who seldom undertake the slightest work without invoking their aid.

Sir Isaac Newton tells us, that the singing women of Osiris were celebrated in Thrace by the name of the muses; and that the daughters of Pierius, a Thracian, imitating them, were celebrated by the same name.

Diodorus Siculus informs us, that Alcman of Messene, a lyric poet who flourished in the 27th Olympiad, 670 years B. C. makes them the daughters of Uranus and Terra. It has been asserted by some ancient writers, that at first they were only three in number; but Homer, Hesiod, and other profound mythologists, admit of nine.

In his hymn to Apollo, Homer says,

> —— By turns the nine delight to sing.

They were generally supposed to be the daughters of Jupiter and Mnemosyne, and were nine in number, Clio, Euterpe, Thalia, Melpomene, Terpsichore, Erato, Polyhymnia, Calliope, and Urania. They have been severally called Castalides, Piarides, Aganippides, Lebethrides, Aonides, Heliconiades, &c. from the places where they were worshipped, or over which they presided. Apollo, their patron and conductor, has received the name of Musagetes, or leader of the muses. The palm tree, the laurel, and all the fountains of Pindus, Helicon, Parnassus, &c. were sacred to the muses. They were generally represented as young, beautiful, and modest virgins, and commonly appeared in different attire according to the arts and sciences over which they presided. See Clio, Euterpe, &c. Their contest with the daughters of Pierus is well known. See Pierides. The worship of the muses was universally established, particularly in the enlightened parts of Greece, Thessaly, and Italy. No sacrifices were ever offered to them, though no poets ever began a poem without a solemn invocation to the goddess who presided over verse.

The following passage translated from Callimachus, expresses the attributes of the muses in as many lines:

Calliope the deeds of heroes sings;
Great Clio sweeps to history the strings;
Euterpe teaches mimes their silent show;
Melpomene presides o'er scenes of woe;
Terpsichore the flute's soft power displays;
And Erato gives hymns the gods to praise;
Polymnia's skill inspires melodious strains;
Urania wise, the starry course explains;
And gay Thalia's glass points out where folly reigns.

MUSE'FUL. *a.* (from *muse.*) Deep thinking; silently thoughtful (*Dryden*).

MU'SER. *s.* (from *muse.*) One who muses; one apt to be absent of mind.

MU'SET. *s.* (In hunting.) The place through which the hare goes to relief (*Bailey*).

MUSEUM, a name which originally signified a part of the palace of Alexandria, which took up at least one-fourth of the city. This quarter was called the museum, on account of its being set apart for the muses and the study of the sciences. See Musæus. Here were lodged and entertained the men of learning; who were divided into many companies or colleges, according to the sciences of which they were the professors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelphus, who here placed his library. Hence the word museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

The museum at Oxford, called the Ashmolean museum, is a noble pile of building erected at the expence of the university, at the west end of the theatre, at which side it has a magnificent portal, sustained by pillars of the Corinthian order. The front, which is to the street, extends about 60 feet, where there is this inscription over the entrance in gilt characters, *Museum Ashmoleanum, schola naturalis historiæ, officina*
begun in 1679, and finished in 1683, when a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq. which were the same day reposited there: several accessions have been since made to the museum; among which are hieroglyphics, and other Egyptian antiquities, an entire mummy, Roman antiquities, altars, medals, lamps, &c. and a variety of natural curiosities.

Museum (British), the museum of the late sir Hans Sloane, containing a great variety of the productions of nature and art, was purchased by the public at 20,000l. for the national use, and deposited in Montagu-house; where it may be rendered of no less general benefit to trade, than to the advancement of natural knowledge and experimental philosophy.

For the purchase of this museum, as well as the Harleian collection of manuscripts, and the Cottonian library, an act of parliament passed in the twenty-sixth year of George II. which incorporates the trustees into a body politic, with a common seal, and empowers them to manage the concerns of this museum.

In this act it is ordered that sir Hans Sloane's collection, the Cottonian library, the Harleian manuscripts, and a large collection of books given by major Edwards, should be placed together in the general repository. 7000l. were also given by major Edwards for the purchasing manuscripts, books, medals, &c.; and in 1772, parliament purchased sir William Hamilton's collection of Greek, Roman, and Etruscan antiquities, and placed them here. And every part is now so excellently contrived for holding this noble collection, and the disposition of it, in the several rooms, is so orderly and well designed, that the British museum may be justly esteemed an honour and ornament to the nation. To this collection his majesty has been pleased to add the royal library of books, collected by the several kings of England; and several recent additions make this museum one of the most interesting objects to either the virtuoso or the man of literature which can well be imagined.

MUSGRAVE (Dr. William), a learned physician and antiquary, was born at Charlton-Musgrave in Somersetshire, about the year 1657; and studied at New-college, Oxford. Having distinguished himself by his knowledge in his profession, and his skill in natural philosophy, he was elected fellow of the Royal Society; and being made secretary in 1684, he continued the Philosophical Transactions from No. 167 to No. 178 inclusive. After having taken his degrees in physic, and being admitted a fellow of the college of physicians, he went and settled at Exeter, where he practised physic with great reputation and success. Being a man of extensive learning, he composed, at his leisure-hours, several curious and valuable works; as, 1. De arthritide anomala sive interna dissertatio. 2. De arthritide symptomatica dissertatio. 3. Julii Vitalis epitaphium, cum commentario. 4. De legionibus epistola. 5. De aquilis Romanis epistola. 6. Inscriptio Terraconensis, cum commentario. 7. Geta Britannicus, &c. 8. Belgium Britannicum. This learned physician died in 1721.

MUSHROOM, in botany. See AGARICUS and LYNCURIUS. To try the quality of mushrooms:—Take an onion, and strip the outer skin, and boil it with the mushrooms: if the onion become blue or black, there are certainly dangerous ones amongst them; if it remain white, they are good.

MUSIC, is both an art and a science, and in either case its object is the combining of sounds in a manner that shall be agreeable to the ear. This combination may be either simultaneous or successive: in the first case, it constitutes harmony; in the last, melody. But though the same sounds, or intervals of sound, which give pleasure when heard in succession, will not always produce the same effect in harmony; yet the principles which constitute the simpler and more perfect kinds of harmony are almost, if not entirely, the same with those of melody. By perfect harmony, we do not here mean that plenitude, those complex modifications of harmonic sounds which are admired in practice; but that harmony which is called perfect by theoricians and artists; that harmony which results from the coalescence of simultaneous sounds produced by vibrations in the proportions of thirds, fifths, and octaves, or their duplicates.

The principles upon which these various combinations of sound are founded, and by which they are regulated, constitute a science, which is not only extensive but profound, when we would investigate the principles from whence these happy modifications of sound result, and by which they are determined; or when we would explore the sensations, whether mental or corporeal, with which they affect us. When we consider with how easy a transition we may pass from the accents of speaking to diatonic sounds, when we observe how early children adapt the language of their amusements to measure and melody however rude, when we consider how early and universally these practices take place, there is no avoiding the conclusion, that the idea of music is connatural to man, and implied in the original principles of his constitution. The principles on which it is founded, and the rules by which it is conducted, constitute a science. The same maxims when applied to practice form an art: hence its first and most capital division is into speculative and practical music.

Speculative music is, if we may be permitted to use the expression, the knowledge of the nature and use of those materials which compose it; or, in other words, of all the different relations between the high and low, between the harsh and the sweet, between the swift and the slow, between the strong and the weak, of which sounds are susceptible; relations which, comprehending all the possible combinations of music and sounds, seem likewise to comprehend all the causes of the impressions which their succession can make upon the ear and upon the soul.

Practical music is the art of applying and reducing to practice those principles which result from the theory of agreeable sounds, whether simultaneous or successive; or, in other words, the conducting and arranging sounds according to the proportions resulting from consonance, from duration and succession, in such a manner as to produce upon the ear the effect which the composer intends. This is the art which we call composition. With respect to the actual production of sounds by voices or instruments, which is called execution, this department is merely mechanical and operative; which, only presupposing the powers of sounding the intervals true, of exactly proportioning their degrees of duration, of elevating or depressing sounds according to these gradations which are prescribed by the tone, and to the value required by the time, demands no other knowledge than a familiar acquaintance with the characters used in music, and a habit of expressing them with promptitude and facility.

Speculative music is likewise divided into two departments; viz. the knowledge of the proportions of sounds or their intervals, and that of their relative durations; that is to say, of measure and of time.

The first is what among the ancients seems to have been called harmonical music. It shews in what the nature of air or melody consists; and discovers what is consonant or discordant, agreeable or disagreeable, in the modulation. It discovers, in a word, the effects which sounds produce in the ear by their nature, by their force, and by their intervals; which is equally applicable to their consonance and their succession.

The second has been called rhythmical, because it treats of sounds with regard to their time and quantity. It contains the explication of their continuance, of their proportions, of their measures whether long or short, quick or slow, of the different modes of time and the parts into which they are divided, that to these a succession of sounds may be conformed.

Practical music is likewise divided into two departments, which correspond to the two preceding.

That which answers to harmonical music, and which the ancients called *melopée*, teaches the rules for combining and varying the intervals, whether consonant or dissonant, in an agreeable and harmonious manner.

The second, which answers to the rhythmical music, and which they called *rhythmopée*, contains the rules for applying the different modes of time, for understanding the feet by which verses were scanned, and the diversities of measure; in a word, for the practice of the rhythmus.

Music is at present divided more simply into melody and harmony; for since the introduction of harmony, the proportion between the length and shortness of sounds, or even that between the distance of returning cadences, are of less consequence amongst us. For it often happens in modern languages, that the verses assume their measures from the musical air, and almost entirely lose the small share of proportion and quantity which in themselves they possess.

By melody the successions of sound are regulated in such a manner as to produce pleasing airs. See Melody.

Harmony consists in uniting to each of the sounds, in a regular succession, two or more different sounds, which simultaneously striking the ear sooth it by their concurrence. See Harmony, and the following treatise.

The ancient history of music, even among the most cultivated nations, is now either so entirely lost or so extremely obscured, that we can give no satisfactory account of it. All therefore which can be expected from this preliminary view, is a short and cursory detail of its primary state, and its most important revolutions, so far as history will enable us to accomplish this design.

It has been pretended by father Kircher and others, that music prevailed in Egypt before it was known in Greece. These authors derive its name from a word which is primitive in the Egyptian language, and attribute the invention of the art to the stridulous murmur of the winds whistling through reeds, or other vegetable tubes, which grew upon the banks of the river Nile. But if this idle and legendary account of the discovery merits any attention at all, it must relate to instrumental music alone: for it cannot be imagined that mankind, if in the least degree attentive to the natural modulation of their own voices, and to such transitions of sound as were agreeable or disagreeable, would have recourse for their ideas of melody to objects so extrinsic and so contingent as the whistling of winds through a reed. Man is certainly as much a musical as he is a vocal animal; nor is the act of singing in him less instinctive than in birds, though his powers are more extensive and more susceptible of culture than theirs. If we believe the accounts of such as have been attentive to the music of the groves, they will tell us, that though the feathered warblers have a musical instinct, yet the modes of its exertion are as really acquired by birds from their parents or tutors as by men. Nor is it easy to conceive a human creature, endowed with the natural powers of musical sensation, and advanced to any degree of maturity, without supposing at the same time that he has tried several musical experiments, and that in some degree he has formed and cultivated his natural organs.

The origin of instrumental music appears to have been at a period much prior to the date of authentic history; and when we look for its epoch or its discoverer, we are carried at once into the wild regions of fable and mythology. The god Mercury, or Hermes, is said to be the inventor of the lyre, by distending strings of different tensions and diameters upon the shell of a tortoise which he found upon the shore. The first exhibition of the fistula, or shepherd's pipe, is ascribed to Pan. But of these beings and their actions little or nothing can be ascertained with proper evidence. We must therefore content ourselves with such later accounts as merit any degree of confidence.

The Grecian lyre, in its original state, seems to have been an instrument of the utmost simplicity: for, according to some, the Mercurian lyre consisted only of three, and according to others only of four strings. These being touched open, could only produce the same number of sounds: from whence we may easily conclude, that the powers of this instrument could not be very extensive. This tetrachord, as some say, was conjoined; others maintain that it was disjoined, and that its intervals were not even diatonic. It is, however, allowed, that its two extremes produced an octave; and that the two intermediate strings divided it by a fourth on each side, with a tone in the midst, in the following manner:

Ut,———Trite diezengménon.
Sol,———Lichanos méson.
Fa,———Parhypate méson.
Ut,———Parhypate hypaton.

This is what Boëtius calls the tetrachord of Mercury; though Diodorus asserts, that the lyre of Mercury had only three strings. This system did not long remain confined to so small a number of sounds. Chorebus, the son of Athis king of Lydia, added to it a fifth string; Hyagnis, a sixth; Terpander, a seventh, to equal the number of the planets; and at last, Lychaon of Samos the eighth.

This is the account of Boëtius. But Pliny says, that Terpander having added three strings to the four which were original, first played upon the cithara with seven strings: that Simonides joined to them an eighth, and Timotheus a ninth. Nicomachus the Geraseuian attributes this eighth chord to Pythagoras, the ninth to Theophrastus of Piereus, afterwards the tenth to Hysteus of Colophon. Pherecratus, in the dialogue of Plutarch, makes the system advance with a more rapid progress: he gives twelve strings to the cythara of Menalippides, and as many to that of Timotheus. And as Pherecratus was contemporary with these musicians, if we suppose that he really said what Plutarch attributes to him, his testimony will have considerable importance in a fact which was obvious to his own immediate observation.

But how shall we obtain any certainty among such a number of contradictions as are found not only in the doctrines of the authors, but in the order of the events which they relate? For instance, the tetrachord of Mercury evidently gives the octave or diapason. How then could it happen, that, after the addition of three strings, the whole scale was found to be diminished by one degree, and reduced to the interval of a seventh? This is, however, what the greatest number of authors leave us to understand; and among others Nicomachus, who tells us, that Pythagoras, finding the whole system composed only of two conjoined tetrachords, which between their extremes formed a dissonant interval, rendered it a consonance, by dividing these two tetrachords by the interval of a tone, which produced the octave.

Whatever be the case, there is at least one thing certain, that the system of the Greeks was insensibly extended as well above as below, till it reached and even surpassed the compass of a disdiapason or double octave; a series which they called a perfect system, and which was likewise termed the greatest and the most unchangeable; because, between its two extremes, which betwixt themselves formed a perfect consonance, were contained all the simple, the double, the direct, or the inverted chords, every particular system, and according to them the greatest intervals, which can take place in melody.

This whole system consisted of four tetrachords, three conjoined and one disjoined; and of a single note redundant, which was added below the whole to complete the double octave; from whence the string which formed it took the name of *proslambanomene*, or the additional string. This, one would imagine, could only form fifteen notes in the diatonic genus; there were, however, sixteen. This was because the disjunction being sometimes perceived between the second and third tetrachord, and at other times between the third and fourth, it happened, in the first case, that the sound *la* or A, the highest in the second tetrachord, the *si* or B natural, with which the third tetrachord began, immediately followed in ascending; or otherwise, in the second case, that the same sound *la*, with which note itself the third tetrachord begun, was immediately followed by *si* or B flat; for the first gradation of every tetrachord, in the diatonic species, consisted always of a semitone. This difference then produced a sixteenth sound, on account of the *si* or B, which was natural or flat according to its various positions in the different tetrachords. The sixteen sounds were expressed by eighteen different names; that is to say, that *ut* or C, and *re* or D, being either the sharpest or the middle sounds of the third tetrachord, according to the two manners of disjoining the tetrachords, they gave to each of these two sounds a name which determined its position.

But as the fundamental sound was varied according to the mode, from the situation occupied by each mode in the general system arose a difference of acuteness and gravity, which very much multiplied the sounds: for though the different modes had many sounds in common, there were likewise some peculiar to each mode, or to some of them alone. Thus, in the diatonic genus alone, the extent of all the sounds admitted in the fifteen modes enumerated by Aliphius amounted to three octaves; and as the difference between the fundamental sound of each mode and that of its contiguous sound was a semitone only, it is evident, that all that space divided by semitones produced, in the general scale, the quantity of thirty-four sounds practised in ancient music; which, if we deduct all the replicates of the same sound, and confine ourselves to the limits of an octave, it will be found to be chromatically divisible into twelve different sounds, as in modern music. This is obvious from the table placed by Meibomius at the front of Aliphius's work. These remarks are necessary to refute the error of those who believe, upon the credit of some moderns, that the whole of ancient music was limited to sixteen sounds.

With respect to the enharmonic and chromatic genera, the tetrachords were divided by very different proportions; but as they always contained four sounds and three consecutive intervals, in the same manner as the diatonic genus, each of these sounds, in its particular genus, bore the same names which corresponded with them in the diatonic. For this reason Rousseau, whom we follow, has not given particular tables for each of these genera. The curious may consult those of Meibomius, placed at the front of the work of Aristoxenus. They will there find six; one for the enharmonic genus, three for the chromatic, and two for the diatonic, according to the situations of each of these genera in the system of Aristoxenus.

Such, in its perfection, was the general system of the Greeks; which remained almost in the same state till the eleventh century, the time when Guy d'Arezzo made considerable changes in it. He added below a new string, which he called *hypoproslambanomene*, or sub-added, and above a fifth tetrachord. Besides this, he invented, as they say, a flat, to distinguish the second sound of a conjunctive tetrachord from the first of the same tetrachord when disjunctive; that is to say, he fixed the double signification of the letter B, which St. Gregory before him had already given to the note *si* or B. For since it is certain that the Greeks had for a long time these very conjunctions and disjunctions of the tetrachord, and of consequence signs for expressing each degree in these different cases, it follows, that this was not a new sound introduced into the system of Guido, but merely a new name which he gave to that sound; thus reducing to one degree what, among the Greeks, had constituted two. It must likewise be observed concerning his hexachords, which were substituted for their tetrachords, that it was less a change of system than of method; and that all which resulted from it was another manner of solfa'ing the same sounds. But the character of Guido, and the alterations which he made in the ancient scale, may be more properly resumed when we reach the period in which he lived. The different accounts of the system and its improvements, of the different kinds of music, and of the modes to be met with among ancient harmonists, are so various and so obscure, that, in these disquisitions, little or no satisfaction can be obtained. For ascertaining with accuracy the diversity of intervals, Pythagoras, the philosopher of Samos, invented the monochord, or the different divisions of one single string by which the consonances were produced, and found the same ratios which are given in the subsequent elements of music, in Malcolm's account of the scale, and in several other authors unnecessary to be enumerated. For a fuller and more exact account of this monochord, and its use, see the History of Music by sir John Hawkins, vol. I. p. 449. where the necessity of applying it to practice is inculcated by Guido.

Had succeeding writers upon the science been more attentive to the real constitution of the scale, and the principles derived from a monochord properly divided, we might have expected their account of the other phenomena in music to have been more precise and more perspicuous; but for a considerable time after that philosopher, the accounts of ancient music transmitted to us are either superficial and cursory, or unintelligible. The modes, of which Aliphius reckoned fifteen, are by Ptolemy limited to seven. Even of the seven Ptolemaic modes, it would seem that five must be merely possible and nominal; two only real and practical. These appear to coincide with the major and minor mode of the moderns, by which effects similar to those ascribed to the ancient modes are produced. Still, however, this hypothesis is attended with some difficulty. The effects attributed to the modes of the moderns seem to be no more than cheerfulness and melancholy; whereas it would appear that different sentiments were thought to be naturally excited by all the different modes of the ancients, such as courage and terror, fury and complacency, &c. Yet if by ancient modes we are to understand any given intervals which predominate in a piece of music, it is far from being easy to conceive any other explication which will so rationally account for the modes of Ptolemy, as that which we have immediately before recited. A more particular detail of this author, of Boëtius, and of Aristides Quintilianus, than it is in our power to give, circumscribed as we are by limits much too narrow for such an undertaking, will be found in sir John Hawkins's History of Music, vol. I. These are some of the chief writers whose works remain to us, and have escaped the depredations of time. Most of the other ancient writers upon music either appear to have been lost, or only to have treated the subject occasionally. Among these may be reckoned Vitruvius, author of a treatise on architecture, who, in his description of theatres, takes the opportunity of proposing some musical improvements, of making some casual observations upon the art, and of describing an hydraulic organ. But as a more particular account of these would throw no additional light upon the theory of ancient music, for this we must once more remit the curious to Meibomius de re Musica, and to the history by sir John Hawkins above quoted.

The province to which our efforts are necessarily confined directs our attention not so much to the history of those who cultivated the art, as to the art itself, and its various revolutions.

The discovery of the monochord and its divisions was not the only speculation in music peculiar to Pythagoras. He likewise thought the earth and seven planets, or solar system, resembled a musical diapason; and from thence formed the romantic idea of the music of the spheres. For a more satisfactory account of this celestial concert, the curious reader may peruse the Somnium Sipionis, a fragment of Cicero, the Observations upon numbers by his commentator Macrobius, and Montucla's History of Mathematics, vol. I.

Pythagoras, the philosopher of Samos, as we have said above, who taught in Italy, was the first who investigated the relations of sound by measuring a musical string, and observing the tones produced by the vibrations of its different parts, whilst the others were at rest. These he expressed by numbers, and thus ascertained the ratio which one sound bears to another. This investigation was afterwards carried farther, and delineated more distinctly, by Euclid; and gave rise to a controversy which divided the theoretical writers on ancient music into two principal sects, viz. the followers of Pythagoras, who maintained that intervals could only be ascertained by the vibrations of sonorous bodies compared one with another; and those of Aristoxenus, who asserted the judgment of the ear to be the ultimate criterion of intervals. Perhaps neither were absolutely right, nor entirely wrong. Without ascertaining by experiments and calculations the distances of tones, or quantities of intervals, we can by no means obtain the same certainty of their exactitude, whether in tuning instruments of fixed scales, or in performing upon those whose notes admit of variation, and where the temperament is immediate and occasional. So far the Pythagoreans are right. Yet the Aristoxenians might likewise urge, that, though we could suppose a being acquainted with all the properties, relations, and modes of quantity, in their full extent; if such a one, with all this knowledge, should attempt from mere theory to compose a piece of good music, he might be eternally engaged in the same employment to no purpose, and have the mortification to see himself every instant outdone by a mere mechanical performer, who had been long inured to judge of intervals, and practised in the laws of harmony. In short, the whole powers of geometry and algebra may be exhausted, without producing a musical strain which will give real pleasure to the ear. An adept, therefore, in this delightful art, will regulate his practice by his theory, and confirm his theory by his practice. He will not imagine the necessity of experiment and calculation superseded by the decision of his ear; nor will he endeavour to extort from the abstract nature of numbers (which are equally applicable to all subjects that contain quantity) those rules which taste and sensation alone can suggest, and of which they are the ultimate standard.

Nicomachus the Gerasenian lived A. C. 60, and wrote a book called Introduction to harmony, which seems to be one of the clearest and most intelligible of the Greeks works.

In the Symposiaca of Plutarch is a dialogue on music, containing many anecdotes with respect to the invention of several different species of music and poetry. There Phrynis and Timotheus are recorded to have been stigmatized for adding what were esteemed supernumerary strings to the lyre, which at that time had only seven, to mark the different degrees of the diapason. But the additional strings were tuned by intervals less than diatonic. This dialogue, however, is acknowledged to be obscure, and its authenticity questioned.

After exploring what can be known concerning the ancient music, from the theories and writings of those whose works have been transmitted to us, the forms and powers of their instruments occur next to be examined. These can only be collected from verbal descriptions, or from designs either expressed in colours or by sculpture. From these, modern musicians have not scrupled to form a most contemptible idea of practical music among the ancients. But are we sure that the descriptions are perfectly complete and thoroughly understood? If they were, does there not still remain a possibility, that they might be tuned and handled in a manner productive of effects to which we are strangers? Of our instruments now in use, the difference between one manner of performing and another is so astonishing, that one should imagine it might render us cautious in forming any conclusions concerning instruments, which are perhaps neither perfectly described nor exactly delineated, described by authors of a period sufficiently distant to render the idioms of the language in which they wrote obscure. And though the forms exhibited in colours or by sculpture may be thought more permanent and more universally intelligible, they are yet sufficiently subjected to the injuries of time to render their representations suspicious. It cannot be doubted, but that the accounts of the ancients, of the power and efficacy of their music, were frequently fabulous and hyperbolical; but still they are such as, when divested of these accidental circumstances, must convince any man of common sense, who admits the evidence of history, that they are superior to what we at present experience in music with all its boasted improvements. It may well be admitted, that the miracles ascribed to Orpheus and Amphion are false in their literal sense; but no person will imagine, that, even among the superstitious and illiterate vulgar, fables of this kind could have obtained any degree of attention, or be entertained with any other sentiments than those of ridicule, if the truths which they adumbrated had not been uncommonly striking. Nor would it have been relished as a tolerable legend, that music had the power of animating stones and trees, if its visible effects upon sensitive beings at that period had not been wonderfully transporting. It is therefore a degree of incredulity which does no great honour to the authority of modern testimony to doubt the assertion of Horace, when he tells us, that, by the force of music, the human savage was allured from his acorns, his brutal pastimes, and his sanguine broils, to the more decent habits and amiable employments of social life. It has been formerly observed, that among such nations as were esteemed barbarous, we meet with no accounts either of music or its instruments, which either deserve credit or attention. It is not easy to conceive how the Jews, who had made such a great progress in arts and civilization, should still have remained so backward in their musical acquisitions, as they must have been, if we take for granted the figures and powers of their instruments, as delineated by Kircher, and transcribed by sir John Hawkins. Nor will the advantages which are generally allowed to the instruments of other barbarous nations afford a satisfactory account how they were able either to compose or perform such pieces of music as we know them to have possessed. We must therefore with good reason suspect, that the authors of such descriptions have either been grossly ignorant of the subject, or shamefully careless and remiss in the performance of their task.

After the long and cruel devastation of the Goths and Vandals, music seems first to have been revived for the service of the church. It was then of two different kinds, one of which was called the Ambrosian and the other the Gregorian chant. Of these, the last prevailed, and became universal, till corrupted by the ignorance or false taste of its teachers and performers. This degeneracy became at last the subject of high remonstrance and complaint. It seems to have consisted in a total negligence of rhythmus, and in a perversion of that licence of gracing the notes, which is so essential to all emphatic and animated music. It became, however, so contagious and diffusive, that monarchs thought the rescue of the Cantus Gregorianus an object worthy of their interposition. They accordingly authorised more profound adepts and more accurate performers to teach and practise it in its purity through their several dominions. The *antiphonaries*, or books of ecclesiastical music, were rectified, and a more correct and legitimate taste re-established. Thus the Cantus Gregorianus once more triumphed over ignorance and barbarity, and obtained a reception worthy of its original sublimity. It is denominated among the French, and by Rousseau in particular, plain chant. That author scruples not to reckon it a precious remain of antiquity. For a short account of the nature and revolutions of this music, may be consulted the article Plain Chant in his Musical Dictionary. From whence it appears, that the Gregorian music was not originally different from the Ambrosian, but the latter only an improvement upon the former. One would be tempted to suspect, that the first gradation of this music towards its decline was occasioned by transferring it from verse to prose. In consequence of which, that strict and inviolable regard to measured sounds, so conspicuous in ancient music, and so effectually preserved by the aptitude of measured notes to measured syllables, was lost. There is, we know, even in prosaic compositions, a rhythmus. The Roman orators were accustomed to scan their sentences in prose. But though even periods of this kind were by no means emancipated from the laws of rhythmus, yet were they much more loose and indefinite than poetical numbers, which were constituted by feet and syllables whose quantities were determined. From thence, and from the cadences by which they are marked, alone, can result that regularity and satisfaction which in the musical ear acquiesces, and without which every thing is unintelligible. It was this religious observation of determined and regular quantities in ancient poetry which preserved and regulated the due proportion of sounds, and which, when abandoned, left the value of notes, with respect to their duration, impossible to be determined, till other characters and signs were superadded, which discovered the real estimate of every note, and showed to what degree it should be protracted, or by what quantity of duration limited. This seems to have been the next advance in musical improvement; but it had one pernicious effect, which was, to render music independent of poetry. Yet these sister-arts seem to be twin-born from heaven; and perhaps, in no case could the laws of nature have suffered a more cruel and unlucky violation than in separating the one from the other. Modulated sound is a more genuine, powerful, and universal vehicle of sentiment, than any articulate or arbitrary signs can possibly be. But articulate signs may be so happily adjusted by convention, as to express degrees, varieties, and modes of sentiment or emotion, which in modulated sounds are less definitely signified, if signified at all. Thus sounds give energy and sweetness to words, words variety and definiteness to sounds.

We have already observed, that Guy d'Arezzio, otherwise named Guido Aretinus, was the inventor of that disposition of the musical scale which is now in use. He could not, therefore, be the author of harmony, which we know to have been practised some centuries before his time, but only of a new set of characters by which it was expressed. This musician, by changing the tetrachords into hexachords, highly improved the scale, discovered more accurately the position of semitones, and rendered its intonation much more practicable. He likewise adapted the syllables *ut*, *re*, *mi*, *fa*, *sol*, *la*, to the various sounds which compose it, from the following Sapphic verses in a hymn to St. John.

UT quent laxis REsonare fibris
MIra gestorum FAmuli tuorum
SOLve polluti LAbii reatum.
SANCTE JOANNES.

The rhythmus in music, or the regular division and measures of sound, had formerly been determined by the quantities of a feet in poetry; and, independent of these, seems to have been entirely indefinite. The invention of a rhythmus capable of subsisting by itself, is ascribed to one Johannes de Muris. Yet there is considerable reason to believe that it had been invented by one Franco, who lived a number of years before him.

In these times there was a secular as well as sacred music. The Troubadours, or Provencal poets, composed songs of different kinds, which they sung to their harps or violins for public entertainment. Hence it happened, that harmony, melody, and rhythm, admitted of immensely greater varieties than they had hitherto done. We have formerly said, that in ancient music, the quantities or values of every note were determined by those of the syllables to which they answered. It is, however, by no means improbable, that at a very early period, in their private rehearsals, or practice for improvement, whether in taste or execution, the musicians frequently played the instrumental parts without being accompanied either by the voice or the words to which they had been set. The impressions of those poetical measures to which the parts corresponded were abundantly sufficient to preserve in the memory of the performer the idea of the rhythm, and of course to determine the value of each particular note. But when airs were either set to pieces in prose, or composed without any regard to syllabical duration, the quantity of each note was absolutely indefinite. When therefore music begun to be set in parts, it was indispensably necessary that the points which mark the notes intended to correspond one with another should be set in direct opposition. Hence the denomination of counterpoint. But when characters, or different forms of characters, were invented for expressing the different durations of sounds, or their relative proportions one to another, the same precision in opposing note to note became less necessary, and was on that account less scrupulously observed. It might, perhaps, be neither an unpleasing nor uninstructive deduction, after having delineated the nature of simple counterpoint, to trace it through all its different species or divisions; but the contracted sphere in which we are at present constrained to move obliges us to confine these excursions. Such readers as may wish more profoundly and minutely to examine this matter, will find it more perspicuously and fully explained in sir John Hawkins's History. To this they may likewise recur for an idea of the characters or methods by which the precise duration of particular notes might be ascertained. For us, it suffices to add, that the method now in practice, which are explained in the following elements, will be found more simple, whilst at the same time it is equally expressive and intelligible.

The airs into which secular music was originally distinguished seem to have been the madrigal, the song, the cantata, the canon. These were vocal, or at least common to voices and instruments; but the solo, the phantasia, the concerto, were progressive changes in instrumental music. By what gradations they proceeded, and who were the inventors of each particular species, we cannot attempt to show; not only because such a disquisition would be incompatible with the limits of our plan, but because we should find it frequently impracticable either to investigate the hints from which such innovations arose, or the persons by whom they were made.

If music be allowed to possess imitative powers, it will follow, that in proportion as the objects are interesting, the imitation must likewise engage and command attention. From this, it will be acknowledged, that as imitation is the chief purpose of dramatic music; as the actions, characters, and situations exhibited in the drama are the most interesting that can possibly be displayed; and as the dramatic is allowed to be the most perfect of all possible imitations; so of all music, the dramatic, in its perfection, ought to be the most powerful and enchanting. It is therefore a research of no small importance to discover when this kind of music was first revived, and by what degrees it arrived at its present state.

It is generally agreed, that the Greeks and Romans sung their tragedies and comedies from beginning to end: but no monument of these compositions remains to us: so that the music of the drama is as really a modern invention as if no such thing had subsisted among the ancients, since the mere knowledge of a fact could by no means throw any light upon the manner in which it was produced. All that has been transmitted to us concerning the ancient theatrical music can only inform us, that it was pathetic and imitative to a high degree. But upon these hints few composers will think themselves sufficiently instructed to proceed. This arduous enterprise, however, was nobly begun and successfully prosecuted by one Jacapo Peri. A poet, whose name was Ottavio Rinuccino, in the city of Florence, having composed a dramatic pastoral upon the story of Apollo and Daphne, engaged this excellent musician to set it. Both being warmed with the same ideas, and animated by the same design, so happily succeeded, that other poets and musicians were generally approved and admired in proportion as they pursued the vestiges of these great masters. A second performance of the same kind, called Eurydice, composed by the authors of the former pastoral, was represented in Florence in the year 1600, upon occasion of the marriage of Mary de Medicis with Henry IV. of France. But a detail of the gradations by which theatrical music rose to its present perfection would be a task too extensive for the limits by which we are circumscribed. Nor is it in our power, for the same reason, to enter more minutely and critically into the nature of those compositions called operas. Let it suffice to add, that, in common with tragedy and comedy, they are representations of action. In consequence of this, they require the same unity of design, the same diversity of characters and passions, with the former. Hence it follows, that some parts of them will be simply narrative, some pathetic, and others more emphatically descriptive. Music suited to the first of these is called recitativo. Its distinguishing characteristics are, to express the nature and degree of sentiment exhibited by the speaker, to be scrupulously adapted to the peculiar genius of that language which it is designed to accompany; and to be exactly modelled according to the accents of that nation, for which it was formed. Some authors have pretended that the irresistible efficacy of melody was founded upon this principle alone. But if that position be true, in what manner shall we account for the wonderful influence of an Italian recitativo upon a British audience, and for other phenomena of the same kind too numerous to be mentioned? Such parts of the music as are intended for more pathetic declamations may be called airs. In these the words, both with respect to their quantity and order, may be treated with greater freedom. The melody is less in the tone of conversation, and the harmony more complex. In this, however, there is no small hazard lest sentiment should be lost in sound; and it requires a great degree of judgment, delicacy, and taste in the composer, at once to fill the harmony and preserve the sentiment. The chorus is intended to express some emphatic event, to celebrate some distinguished hero, or to praise some beneficent god. It is properly the voice of triumph and exultation. The harmony should therefore be as full and expressive as possible. But for the rules of such compositions, one must refer the reader to such theoretical and practical musicians as have been most successful in describing and cultivating dramatic music. What remains for us is to subjoin a list of those who have been most remarkable for their accuracy in the theory, or for their excellence in the practice, of music.

Of John de Muris we have already spoken, who lived in the year 1330, and to whom, by mistake, has been attributed the invention of those characters by which, in modern times, the value of notes, and their relative proportions one to another, have been ascertained. But this expedient for making visible the different durations of notes as constituent of one rhythmus or particular movement, we have found to be first introduced by one Franco, who lived prior to John de Muris.

Lasus was the first who wrote on music; but his work is lost, as well as several other books of the Greeks and Romans upon the same subject. Aristoxenus, the disciple of Aristotle, and leader of a sect in music, is the most ancient author who remains to us upon this science. After him came Euclid of Alexandria. Aristidis Quintilianus wrote after Cicero. Alyphus afterwards succeeded; then Guadentius, Nicomachus, and Bacchius.

Marcus Meibomius has favoured us with a beautiful edition of these seven Greek authors, with a Latin translation and notes.

Plutarch, as has already been said, wrote a dialogue upon music. Ptolemy, a celebrated mathematician, wrote in Greek a treatise intitled The Principles of Harmony, about the time of the emperor Antoninus. This author endeavoured to preserve a medium between the Pythagoreans and the Aristoxenians. A long time afterwards, Manuel Pyrennius wrote likewise upon the same subject.

Among the Latins, Boëtius wrote in the times of Theodoric; and not distant from the same period Martianus, Cassiodorus, and St. Augustine.

The number of the moderns is almost indefinite. The most distinguished are, Zarlino, Salinas, Valgulio, Galileo, Doni, Kircher, Mersenne, Parran, Perault, Wallis, Descartes, Holden, Mengoli, Malcolm, Baretti, Vallotti, Marcus Meibomius, Christopher Simpson; Tartini, whose book is full of deep researches and of genius, but tedious from its prodigious length, and perplexed with obscurity; and M. Rameau, whose writings have had this singular good luck, to have produced a great fortune without being read almost by any one. Besides, the world may now be spared the pains of perusing them, since M. D'Alembert has taken the trouble of explaining to the public the system of the fundamental bass, the only useful and intelligible discovery which we find in Rameau's writings. To these we may add Rousseau and Dr. Smith, author of a learned and mathematical treatise, intitled, Harmonics, or The Philosophy of Musical Sounds; Mr. Stillingfleet, author of the Principles and the Power of Harmony, or An Explication of Tartini's System; Dr. Pepusch, and his noble pupil the lord Abercorn; Mr. Avison, late organist at Newcastle, who wrote a treatise on Musical Expression with the politeness and elegance of a gentleman, the depth and precision of a scholar, the spirit and energy of a genius. Among the authors already mentioned, it would be unpardonable to omit the names of sir John Hawkins and Dr. Burney, each of whom has favoured the world with a history of music. There are also valuable treatises by Gunn, Kollman, Maxwell, Shield, and Dr. Calcott. An abridgement of the Musical Grammar of the last-mentioned ingenious author is attempted below: and we trust it will be found more worthy the attention of our readers than any thing else we could present to them on this subject. We still, however, beg to refer to the original work, for much curious and valuable matter, which we should not be justified in introducing here.

ELEMENTS OF MUSIC.

PART I.—THE NOTATION OF MUSIC.

Chap. I.—Of the Staff.

Five lines drawn over each other, form a staff, or support for the notes of music.

On these lines, and in the spaces between them, the heads of the notes are placed.

The lines and spaces of the staff are counted upwards, from the lowest to the highest.

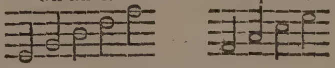
Every line, or space, is called a degree: thus the staff includes nine degrees, viz. five lines, and four spaces.

The notes of music consist generally of two parts, a head and a stem.

The head is either open or close (that is, white or black); and must always be placed on a line, or in a space.

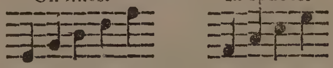
The stem may turn up or down, without making any difference in the music.

White notes.



On lines. In spaces.

Black notes.

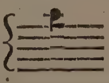


On lines. In spaces.

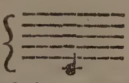
When more than nine notes are wanted, the spaces above and below the staff are used, and two more degrees are gained.

If more notes than these are required, then added lines are drawn above or below the staff, and the notes are placed on them; thus,

Line above.



Line below.



Any number of lines may be added above or below; thus the degrees of the staff are increased at pleasure.

In music for keyed instruments, when a staff is wanted for each hand, they are joined together by a brace; the upper staff for the right part, and the lower staff for the left.

When more than two staves are joined together by the brace, they contain music for different voices, or instruments, to be performed at the same time. This union of staves is called the score.

Chap. II.—Of the Clef.

The notes of music are named from the first seven letters of the alphabet,

A, B, C, D, E, F, G.

When the melody, or tune, exceeds these seven, the same series of letters must be repeated.

A clef is a mark representing a letter, placed at the beginning of the staff, to determine the names of the degrees, and is always situated on a line. There are three clefs:

The F.

The C.

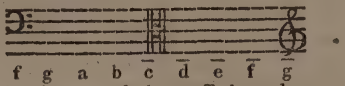
The G.

These are commonly called the base, the tenor, and the treble.

The sounds of music are distinguished by their difference in respect of pitch, and divided into high and low: the high sounds are placed in a staff with the G clef, and called treble; the low sounds are placed in a staff with the F clef, and called base.

The upper sounds of the base, and the lower ones of treble, are also called tenor, and sometimes placed in a staff with the C clef.

These three clefs are five degrees distant from each other; the C or tenor clef, being the note where the base ends and the treble begins. The G or treble clef, is five degrees above; and the F or base, is five degrees below, both inclusive.



All the degrees of the staff depend upon the clef; and consequently take their names from that line on which the clef is placed. It must always be remembered, that these clefs are representatives of the letters, f c̄ and ḡ.

The G clef must turn on the second line of the staff; all the notes on that line are called ḡ; the other degrees take their names from that, as the clef line.

The F clef must be placed on the fourth line of the staff, so that the two dots are in the third and fourth spaces: all the notes on that line are called f; the other degrees take their names from that, as the clef line.

When the C clef is placed so that the two cross strokes enclose the middle line, it is called the counter tenor, or viola clef.

The counter tenor clef is used for the high voices of men in vocal music, and for the viola or tenor violin in instrumental pieces.

When the C clef is placed so that the two cross strokes enclose the fourth line, it is called the tenor clef.

The tenor clef is used for the middle voices of men, and for the violoncello or base violin, in instrumental music, when the passage ascends above the base staff.

When the C clef is placed so that the two cross strokes enclose the lowest line, it is called the soprano, or canto clef.

The soprano clef is used for the voices of females and children. In Italy and Germany, no other clef is in general use for the harpsichord; the G clef being reserved for the violin, flute, &c.

In old vocal music, the C clef is placed on the second line, and called the mezzo soprano.

In old church music, the F clef is placed on the third line, and called the baritono.

In old French music, the G clef is placed on the first line, and called the high treble.

Chap. III.—Of the Notes.

Of notes in general.—The notes of music represent sounds, with their difference of pitch, and their duration in time. These two qualities are called the tune and time of notes.

When to any series of the seven letters the eighth is added, the whole number is termed an octave; and the word is frequently used to express the two extreme notes of the series, the first and the eighth.

That series of the seven letters which begins and ends with C, ascending or descending, is most satisfactory to the ear.

c d e f g a b c̄

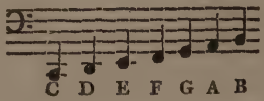
On keyed instruments, these notes are performed by striking the long keys, whose names are known by their situation with respect to the short keys, which are generally black.

The black keys are placed in alternate divisions of two and three, throughout the key-board; and, as the long key between the two short ones is always D, the other six letters may be readily found from that; E being the next long key towards the right hand; C the next towards the left, &c. &c.

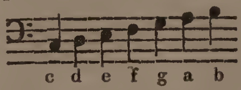
The C nearest the middle of the instrument is the tenor clef note; the next G towards the right, is the treble clef note; and the nearest F towards the left, is the base clef note.

To distinguish the different notes of the same letter from each other, the Germans have adopted a literal notation, called their tablature, which, from its ingenuity and utility, deserves to be more universally known than it is at present.

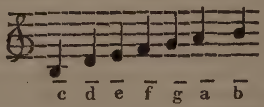
The lowest series of seven notes, which includes both the divisions of short keys in the key-board (beginning with the two), is called by the Germans the great octave, being expressed by capital letters; thus,



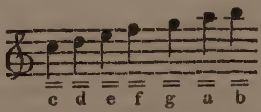
The next series of seven notes is called the small octave, expressed with small letters; thus,



The next series commences with the C clef note, including the G clef; and being expressed by a small stroke over each letter, is called the once-marked octave.



The last series in general use is called the twice-marked octave.



The few notes below the great octave are marked with double capitals, and called contratones. Those above the treble form another series, called the thrice marked octave.

Any musical example, in which all the notes are of equal length, may be expressed by this tablature, without the assistance of the staff or of the clef. According to this notation we may observe,

The F clef note is the small f.

The C clef note is the once marked c̄.

The G clef note is the once-marked ḡ.

In vocal music these notes are sung with the syllables introduced, about the year 1022, by Guido; *ut, re, mi, fa, sol, la;* called by his followers the hexachord.

The French retain the original six, with the addition of *si* for the seventh.

ut, re, mi, fa, sol, la, si, ut.
c d e f g a b c

The Italians, for the sake of a softer pronunciation, have changed the *ut* into *do.*

do, re, mi, fa, sol, la, si, do.

The general scale of notes was formerly called the gammut, from the Greek letter gamma, placed on the lowest line of the base staff, or great G of the German tablature.

Of the tune of notes.—The tune of notes depends upon their relation to each other, and upon the distances between them. The intervals between the degrees of the scale are unequal; and, as some are nearly twice the distance of others, the words tone, and semitone, are employed to express them.

Those notes which on the key-board are not separated by a short key, are said to be distant from each other one semitone; those which have a short key inserted between them, are distant two semitones, or one tone. Thus, the distances between BC and between EF, are semitones; and those between CD, DE, FG, GA, and AB, are tones;—therefore, every series of the eight regular sounds, or of the octave, contains five tones and two semitones.

The greatest care must be taken not to misunderstand the words note and tone. A note is the sound which is heard, or the mark which represents it on the staff; but a tone is the distance between two notes, which are called by the names of two adjoining letters, and separated by one single key of the instrument. Thus, the distance from A to B is a tone; and therefore A is a tone lower than B, and B a tone higher than A.

The same observation must be applied to the semitones, which are sometimes called, though improperly, half notes. The distance from B to C is a semitone; therefore B is a semitone lower than C, and C is a semitone higher than B.

By comparing the sounds C D E F with the following sounds G A B C, we find that the distances of both these fourths consist exactly of two tones and a semitone; therefore any tune, formed by one, will be exactly similar to that of the other.

These two fourths, taken in succession, form a scale, of which the chief sound being C, is from thence called the key note. The descending series of this scale corresponds with the common tune of eight bells.

The effect of these notes to the ear depends upon the position of the semitones. This may be easily perceived by playing eight notes, from d, or e, or any part of the scale, which will not produce the same melody.

But if the same letters, in any octave higher or lower, are taken, the same tune will be heard.

This series of sounds, which is performed on the organ, &c. with the long keys, is called the natural scale, to distinguish it from that which employs the short keys intermixed with the others, called the chromatic, or artificial.

In the vocal scale of the solfeggio, the place of the semitone is ascertained by the syllables *mi fa* and *si do;* between all the others is the distance of a tone.

As the whole doctrine of melody, or the tune of notes, must depend on a right conception of the two semitones, and their places in the scale, great attention should be paid to this part of the subject by every musical student.

Of the time of notes.—The duration of a note, with respect to time, is known by its particular form; and the distinction between notes in this respect is shown by making them white or black, and by the stem and the hook.

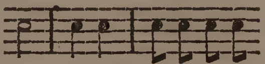
The three principal notes are, the minim, the crotchet, and the quaver.

The minim is a white note with a stem, made thus, and is as long as two crotchets, or four quavers.

The crotchet is a black note with a stem, made thus, and is as long as two quavers.

The quaver is a black note with a stem and a hook, made thus, and may be divided into semiquavers, or four demisemiquavers.

The proportions of these three principal notes to each other are therefore as under,



One Two Four
Minim. Crotchets. Quavers.

When the quaver is divided into smaller portions, the two following notes are employed:

The semiquaver, which is made like the quaver, but with two hooks, being half the length of the quaver; and

the demisemiquaver, which has three hooks, being one quarter the length of the quaver.

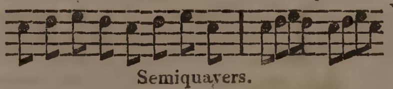
In slow music, especially that in the church style, two longer notes are used; the semibreve and the breve.

The semibreve is a round white note, without a stem, and is as long as two minims, or four crotchets.

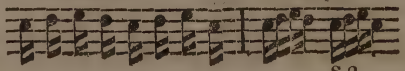
The breve is a square white note, and is as long as two semibreves, four minims, or eight crotchets.

Those notes which are made with hooks may be grouped together by two, three, or four, &c. Thus:

Quavers.
Detached. Grouped.



Semiquavers.
Detached. Grouped.



This method is not only convenient in writing, but assists the eye in ascertaining the proportion of the notes, and is of particular use in vocal music, to distinguish the notes which are to be sung to each syllable.

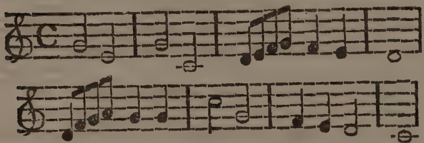
Every musical piece is divided into equal portions of time, called measures. These are ascertained by straight lines, called bars, drawn down the staff. All the notes, therefore, contained between two bars, constitute one measure. The use of bars is not to be traced higher than the time when the English translation of Adrian le Roy's book on the tablature was published, viz. the year 1574; and it was some time after that before the use of bars became general. To come nearer to the point, Barnard's cathedral music, printed in 1641, is without bars; but bars are to be found throughout the Ayres and Dialogues of Henry Lawes published in 1653; from whence it may be conjectured that we owe to Lawes this improvement in music.

Every measure must contain a certain number of notes, according to the time marked at the beginning of the movement. Thus in common time, each measure includes a semibreve, or its value in minims, crotchets, or quavers, intermixed as the melody requires. The exact length of the measure is known by regularly dividing the time into equal portions, whether the notes themselves are long or short; as every measure must be precisely equal in time, during the continuance of the movement.

There are two chief species of time, common or equal—and triple or unequal time. In the first, we count two, four, or eight in every measure; in the last we count three, or six.

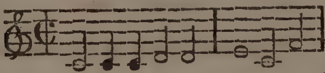
I. Common or equal time, contains one semibreve, two minims, four crotchets, eight quavers, or their value, in every measure. This time is known by a semicircle placed at the beginning of the staff, after the clef, thus:

(Handel: "See the conquering").



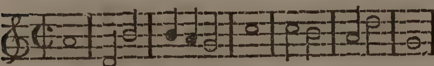
The barred semicircle is used to denote a quicker movement, and is called alla breve; because it was formerly written with one breve in a measure, thus:

(Orlando Gibbons, Dr. Boyce, V. II. 59: "O clap your hands").



This is now more commonly written with one semibreve in a measure, by dividing those of the alla breve into halves.

(Handel, "Saul," Dr. Arnold's edition of Handel's Works, No. 112, p. 36: "Our fainting courage").



All other measures are marked by figures, placed one over the other at the commencement of the staff.

The figure 2 above the figure 4, indicates two crotchets, or one minim, in each measure; and is called half time, being the division of the semibreve.

(German Hymn, Pleyel).

The most usual measures expressed by figures placed at the beginning of the staff, are the following:

3	3	3	6	6	9	9	12
2	4	8	4	8	8	16	8

Of these figures, the upper one shews how many parts are contained in the measure; and the lower one represents a word, showing how many of these notes constitute a semibreve. 2, signifies minims; 4, crotchets; 8, quavers, &c.; as in the following table:

3 Three 2 Minims	3 Three 4 Crotchets	3 Three 8 Quavers
6 Six 4 Crotchets	6 Six 8 Quavers	9 Nine 16 Semiquavers
	12 Twelve 8 Quavers	

When it is necessary to lengthen a note by half its value, a dot is placed after it. Thus, a dotted minim is as long as a minim and a crotchet, or as three crotchets.

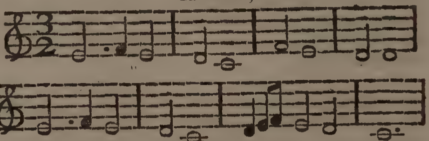
A dotted crotchet is as long as a crotchet and a quaver, or as three quavers.

II. Triple, or unequal time.—Of this time there are three different species in use; namely,

1. Three minims,
2. Three crotchets, } in a measure.
3. Three quavers,

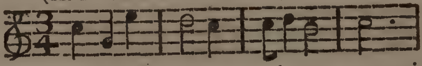
1. One dotted semibreve, or three minims, in every measnre; thus,

(Handel's Italian songs, No. 64, "Verdi prati—Alcina").



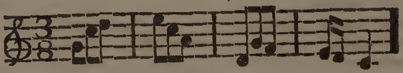
2. One dotted minim, or three crotchets, in every measure.

(H. S. I. No. 66: "Fell rage—Saul").



3. One dotted crotchet, or three quavers, in every measure.

(H. S. II. 128: "No, let the guilty tremble—Saul").



When two measures of three crotchets, or of three quavers, are united in one, by the omission of a bar, the time is called compound common;—common, because every measure is equally divided; and compound, because each half is a single measure of triple.

III. Compound common time has three species, in general use:

1. Six crotchets,
2. Six quavers, } in every measure.
3. Twelve quavers,

When two measures of six quavers are further united into one, they form a double compound of twelve quavers in each measure, and are equal to four measures of three quavers. The omission of the bars makes some difference in the appearance of the music, and influences the counting, according to the degree of quickness in which the piece is performed. But, in other respects, the division of the measure has no power of altering the real nature of the time or tune; nor can the auditor perceive whether the triple time performed be expressed by the figures

$\frac{12}{8}$ $\frac{6}{8}$ or $\frac{3}{8}$

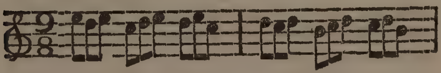
IV. Compound triple time is formed by dividing the meaures of simple triple into nine parts, and by dotting the measure note of the original time. Of this there are three species:

1. Three minims divided into nine crotchets.
2. Three crotchets divided into nine quavers.
3. Three quavers divided into nine semiquavers.

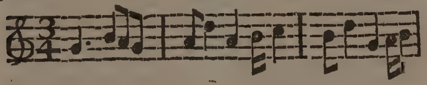
By a mere change of notation, the advantage is gained of presenting the simple measures clear to the eye, without the incumbrance of a dot to each minim.

(2.) Nine quavers, or three crotchet time, divided into triplets.

(H. S. IV. No. 319: " Consider, fond shepherd—Acis and Galatea").

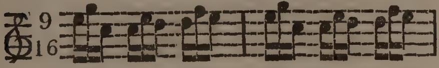


The commencement of this song, and the other parts, are in simple triple; thus,



(3) Nine semiquavers, or three quaver time, divided into triplets.

(H. S. II. No. 156: " Hush, ye pretty warbling choir—Acis and Galatea").



From these two species of compound time (common and triple), arise various kinds of mixt measures, which are in some parts equally, and in others unequally divided.

The triplets of common time, which are found in the place of each crotchet of the measure, have sometimes the figure 3 placed over them; but are generally known by being grouped together, and then form one of the single parts of the whole measure.

The same use of the triplet occurs in triple time when the measure note is divided occasionally into three parts, instead of two.

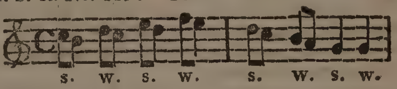
There is also a species of time, call quintuple, which contains five crotchets in a bar; but it is very seldom used.

Tartini considered this quintuple proportion as unfit for melody, and impossible to be executed. Time has shewn, that neither of these judgments were well founded.

Of the accent of notes.—The bars of music are not only useful for dividing the movement into equal measures, but also for shewing the notes upon which the accent is to be laid.

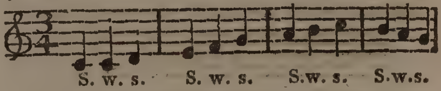
The measures of common time are divided into four parts; of these, the first and third are accented; the second and fourth unaccented. In the course of this treatise the accented will be termed strong parts, and the unaccented, weak parts of the measure.

(H. S. II. No. 119: " Praise the Lord—Esther").



The measures of triple time consist of three parts; the first strong, the two others weak; although the last part is rather strong, in comparison of the middle part.

(H. S. III. No. 233: " Up the dreadful steep").



In slow common time the accents are more frequent; but they are found in the same proportion on the first, third, fifth, and seventh quavers, which are the strong parts, while the second, fourth, sixth, and eighth, are the weak parts.

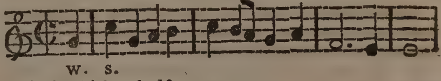
In three crotchet time, when divided into quavers, the first, third, and fifth quavers are strong; the second, fourth, and sixth, weak.

In six quaver time, the first and fourth quavers are strong; the others weak.

From the nature of accent arises the necessity of beginning some movements with only part of a measure; thus,

(1.) With a single weak part.

(H. S. III. No. 163: "The smiling dawn—Jephtha").



(2.) With a half measure.

(H. S. III. No. 162: " Welcome as the cheerful day—Jephtha").

When the composer intends that the weak parts of the measure should be made of more importance than the strong parts, such deviation from the regular accent will be termed emphasis.

The Italian words, *rinforzando, sforzato,* or their contractions, *rinf. rf. sforz. sf.* are often used to mark the emphasis, and sometimes are placed over accented notes.

As every species of measure may be subdivided by accents, according to the degree of quickness in which it is performed; so also the weak parts of every measure may be occasionally made emphatic at the pleasure of the composer.

To this species of effect may be referred all syncopated or driving notes, which begin on the weak, and end on the strong part of the measure.

Chap. IV.—Of the Rests.

When, in the course of a movement, silence is required for one or more parts of a measure, that silence is denoted by a rest, or rests, which are counted exactly in the same time as their corresponding notes would be, if performed.

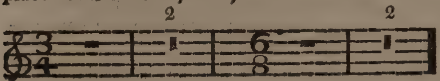
The rests of the white notes are made in the middle of the staff; thus,

Rest of the breve, Semibreve. Minim.

1. The breve rest extends from line to line.
2. The semibreve rest is made below the line.
3. The minim rest is made above the line.

The semibreve rest is also used in triple and compound time, to express the silence of one whole measure; and the breve rest is used for the silence of two measures.

In this last instance the figure 2 is generally placed over the rest; thus,



The rests of the black notes are made thus,

1. The crotchet rest turns to the right.
2. The quaver rest turns to the left.
3. The semiquaver rest turns to the left, and has two marks.
4. The demisemiquaver rest has three marks, and turns to the left also.

As the rests are inserted in the measures, to fill up the time when no sounds are to be heard, the performer should, of course, pay particular attention to the termination of the notes which precede them.

In playing keyed instruments, the rests are often much neglected: and, unless the player carefully raises the finger from the key (but not too far) at the exact commencement of the rest, the intended effect is destroyed.

Indeed Bach remarks, with his usual judgment, that to form a clear, pleasing, and expressive performer, three things are requisite:

1. To play correctly, by covering every note with the finger before it is struck (when possible), so that, in the most difficult passages, the motion of the hands may be scarcely perceived.
2. To make the instrument sing, by taking one finger off the key at the instant the other strikes the following note; and by never playing the notes short or detached except when expressly marked.
3. To play with expression by forcing the finger down upon the key (already covered and lightly touched,) according to the accent or emphasis.

On this subject see also Clementi's Introduction, p. 15. Dussek's Instructions, p. 8. Hullmandel's Principles, p. 19.

Chap. V.—Of the Sharps, Flats, &c.

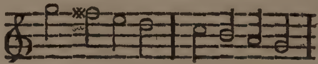
In explaining the tune of notes, the two different intervals of tone and semitone have been noticed. Every tone in the natural scale, is divided into two semitones, by an intermediate sound. This sound is produced, upon keyed instruments, by striking the short key inserted between two long ones, which are consequently tones to each other.

Of the sharps.—When the short key is to be played, instead of the natural note below it (on the left), then the same letter is used, with the additional term sharp.

Thus, to make another fourth, similar to the upper one of C, with two tones and a semitone, and placed immediately above it, at the distance of a tone; the F natural must be omitted, and the F sharp taken in its stead.

The character placed before F is called a sharp.

These two fourths united, form a new scale, of which G is the key note, exactly similar to C, but five degrees higher. Its descending series proves, by the melody, that the tones and semitones are between the same degrees of the scale.



As the scale of G is made complete by this alteration of the F alone, F is reckoned the first sharp.

For a similar reason (that of forming a new fourth above the upper one of G scale), C is termed the second sharp. Thus the series of sharps ascends by fifths; which, in respect of the letters, is the same as descending by fourths.

F	C	G	D	A
1	2	3	4	5

These sharps are performed, on keyed instruments, with the five short keys above; that is, on the right hand of the long ones: the division of two consists of C sharp and D sharp; the remaining three are F sharp, G sharp, and A sharp.

But, since there are no short keys between E and F, nor between B and C, which are only semitones to each other, F natural is employed to express E sharp, and C natural to express B sharp.

When these notes, E and B, become sharpened, their own long keys are never used; and, by their introduction, the series of sharps is extended to all the seven notes.

F	C	G	D	A	E	B
1	2	3	4	5	6	7

Of the flats.—When the short key is to be played, instead of the natural note above it (on the right), then the same letter is used, with the additional term flat.

Thus to make another fourth similar to the lower one of C, with a semitone and two tones, placed also below it (extending to the left), at the distance of a tone, the B natural must be omitted, and the B flat taken in its stead.

The character placed before B is called a flat.

These two fourths united, form a new scale, of which F is the key note; exactly similar to C, but five degrees lower. Its descending series proves, by the melody, that the tones and semitones are between the same degrees of the scale.

As the scale of F is made complete by this alteration of B alone, B is reckoned the first flat. For a similar reason (that of forming a new fourth below the lower one of the F scale) E is termed the second flat. Thus the series of flats ascends by fourths, which in respect to the letters, is the same as descending by fifths.

B	E	A	D	G
1	2	3	4	5

These flats are performed, on keyed instruments, with the five short keys below; that is, on the left of the long ones: the division of two consists of E flat and D flat; and the other three are B flat, A flat, and G flat. For the reason given concerning the sharps, B natural is employed to express C flat, and E natural is employed to express F flat. Thus the whole series of seven flats is completed.

B	E	A	D	G	C	F
1	2	3	4	5	6	7

This series is exactly the reverse of that given of the sharps.

It must be recollected, that every one of the short keys has two different letters for its name, according to the natural note for which it is employed.

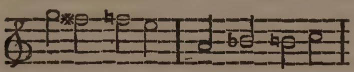
Thus, the middle key of the three short ones is equally used as the third sharp in the place of G natural below it, and as the third flat in the place of A natural above it.

When any number of sharps or flats are placed after the clef, at the beginning of the staff, they affect all the notes of the same letter in every octave throughout the movement, and are termed the signature.

Those which occur in the course of the movement, in addition to the others, are termed accidental, to distinguish them from those of the signature, which are essential to the scale of the original key note.

The accidental flats and sharps only affect the notes which they immediately precede, and those of the same letter which follow them in the same measure; but, if one measure ends, and the next begins, with the same note, the accidental character which alters the first note, is understood to affect the second.

Of the natural.—When any note, which has been elevated by a sharp, or depressed by a flat, is to be restored to its original place, the character called a natural is employed; which lowers the sharpened note, or raises the flattened note; thus,



The natural, although a very ancient character, was not used by Morley, Simpson, or Playford. They always employ the flat to take away the sharp, and the sharp to take away the flat, in the same manner as we now use the natural.

The natural, although evidently an accidental character, and a more general expression for the two others (the sharp and the flat), is sometimes placed essentially at the beginning of a strain, when a former part of the same movement has had a sharp or flat in its signature. (See Steibelt's sonatas, Op. 37, Turkish Rondo, p. 10.) According to its power, therefore, of raising or lowering any note of the scale, the natural must be always considered as representing a sharp or a flat.

After all the notes of music have been made sharp, the same series of letters begins again, and F, being the first, takes the name of F double sharp. It is performed, on keyed instruments, by striking the long key G natural; which is not, however, to be reckoned then as a tone from F natural, being placed on the same degree as F, and also consisting of two chromatic (or minor) semitones.

In the same manner, after all the seven notes of music have been made flat, the same series of letters begins again with B; and that, being the first, takes the name of B double flat.

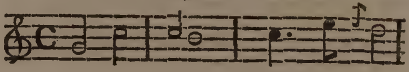
It is performed by striking the long key A natural two chromatic semitones lower. It is worthy notice, that, as the first sharp is the lowest, and the first flat the highest of the three short keys which are near to each other; so the first double sharp, and the first double flat (the only two in general use) are played with the two long keys which are enclosed by F sharp and B flat.

Chap. VI.—Of Graces, Characters, Marks of expression, and Abbreviations.

Of graces.—The principal graces of melody are, the appoggiatura, the shake, the turn, and the beat; with the mordent, beat, slide, and spring, peculiar to the Germans. The chief ornaments of harmony are, the arpeggio, tremando, &c.

I. The appoggiatura (vorschlag) is a small note placed before a large one of longer duration, from which it generally borrows half the value, and always occurs on the strong part of the measure.

The appoggiatura, as written.

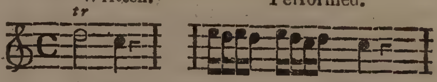


As performed.

When a small note follows a larger one, and depends upon that for its time, the name of afternote (nachschlag) will be used in this work, to distinguish it from the appoggiatura.

This grace always occurs on the weak part of the measure.

II. The shake (triller) consists of a quick alternate repetition of the note above, with that over which the mark is placed; and commonly ends with a turn from the note below. It is usually denoted thus:

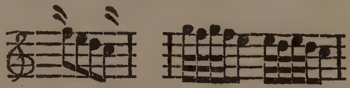


Written. Performed.

In this example the upper note is accented: there are, however, instances in which the composer seems to have designed that the lower note, or that over which the shake is placed, should be accented.

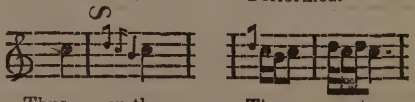
A series of continued shakes, on notes rising or falling by degrees, is called by the Germans triller kette, and by the Italians catena di trilli, both signifying a chain of shakes.

The passing shake (præll triller) is expressed in Germany by a particular character; and its definition varies with different masters, and in different passages. The explanation of Dr. Arnold (Op. XII. p. 38.) is therefore given here, with the mark he adopted for it.



Written. Performed.

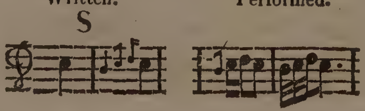
III. The turn (doppelschlag) employs the note above and that below, in the following manner:



Written. Performed.

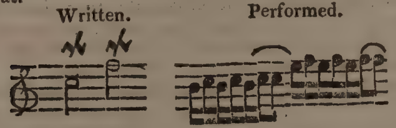
Thus, or thus. Thus, or thus.

The inverted turn begins from the note below. (Dr. Arnold, Op. XII. p. 38).



Written. Performed.

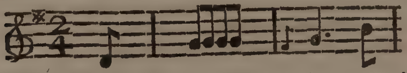
IV. The beat is the reverse of the shake (but without the turn), and made generally at the distance of the semitone below; therefore all the natural notes, excepting C and F, require the note below them to be accidentally sharpened for the beat.



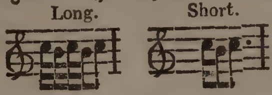
Written. Performed.

In some cases of regular ascent, it is recommended not to make the beat with the semitone, unless particularly marked. (See Clementi, p. 11.)

In the half beat (zusammenschlag) the inferior note is struck only once, and at the same time with the principal note, but is immediately quitted. This is frequently used upon the organ, and particularly in the base. It may be written by a small note, like a short appoggiatura, and is very similar to the acciaccatura of the Italians.

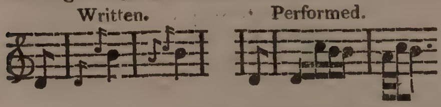


V. The German mordent (beisser) is a species of beat, commencing with the note itself, and is either long or short; thus,



Long. Short.

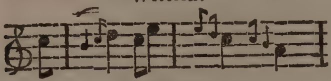
VI. The German beat (anschlag) consists of two small notes, which form a skip, and descends one degree upon the principal note.



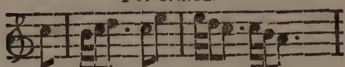
Written. Performed.

VII. The German slide (schleiffer) consists of two small notes, which move by degrees; thus,

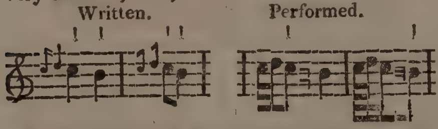
Written.



Performed.



VIII. The German spring (schneller) consists of two small notes, like the Italian mordente, but very distinct; thus,



Written. Performed.

To these graces of melody may be added those of harmony; the tremolo (bebung), or reiteration of one note of the chord; the tremando, or general shake of the whole chord; and the arpeggio (brechung), or imitation of the harp, by striking the notes of the chord in quick and repeated succession.

Clementi (Introduction, p. 9), has given an explanation of two different characters used for a chord (or combination of several sounds struck together), upon keyed instruments.

1. When a waving line is placed vertically before the chord, the notes are played successively, from the lowest ascending to the highest, and retained down the full time of the chord.

2. When an oblique line passes through the chord, it is played as before, with the addition of a note where the oblique line is placed; but this added note is not to be kept down.

Of the characters.—Characters used in music which do not form a part of any particular class, like the clefs, notes, rests, sharps, flats, naturals, or graces, are the tye or ligature, the pause, the repeat, the direct, the single bar, and the double bar. But, as the tye is similar in form to the slur, it will be classed among the marks of expression in the next section.

The pause (𝄐) is placed over a note, to signify that the regular time of the movement is to be delayed, and a long continuance of the sound made on that part of the measure.

If the pause is placed over a rest, then a stop of considerable length is made; and the part must be silent.

The same character is employed in those songs of Handel, Hasse, Vinci, &c. which have a second part, and are marked da capo, to shew the note upon which the piece is finally to terminate; but it is not always followed by the double bar.

The repeat (𝄋) is a sign employed to shew the place to which the performer must return to repeat the passage. It is usually found in rondos and da capo airs; and it marks that place, in the first strain, where the repetition is to commence. This mark is called in Italian, segno, or the sign.

The direct (w) is a sign employed at the end of the staff, to shew upon what degree the first note of the following staff is placed.

When the inner sides of two bars are dotted, all the measures between them are to be repeated. See an instance of this kind of repetition, (H. S. I. No. 68: "Sin not, O King—Saul").

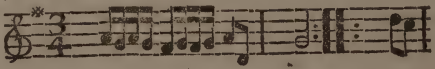
The word bis (twice) is sometimes placed over passages of this kind, whether the bars are or are not dotted.

The double bar is placed always at the end of a movement, and is sometimes used at other parts, to shew the rhetorical termination of a strain.

If the double bar is dotted on one or both sides, all the measures on the same side with the dots are to be repeated from the beginning, or from the antecedent double bar.

When the rhetorical termination of a strain does not coincide with the grammatical accent, the double bar is then totally distinct from the single bar, and the measures are only reckoned between the single bars, although the double bar may intervene.

(H. S. V. No. 374: "Above Measure—Semele").



This double bar does not affect the measure in which it is placed, but the time is kept exactly as if it were not inserted.

As it appears, from the preceding observations, that the double bar is very different and distinct from the single bar, the grammatical use of the latter must not be confounded with the rhetorical employment of the former.

If every piece of music ended with a complete measure, and if the necessity of commencing with single times did not sometimes exist, the double bar might be neglected; but, as it is important to mark the termination of those strains which have their last measures incomplete, this character is adopted, and the double bar bears the same relation to the strain as the single bar does to the measure.

Every measure contains a certain number of notes, which are terminated by the single bar; and every strain includes a certain number of measures which are terminated by the double bar.

The chief *marks of expression* are, the slur, and the dash or point; to which may be added the tye, or ligature.

The tye is an arch drawn over two notes on the same degree, uniting them into one. Upon keyed instruments, the first only is struck; but the finger is kept down during the time of both.

The tye is also used to express those syncopated notes which, in the ancient music, were divided by the bar.

The slur is a similar arch, drawn over two or more notes, upon different degrees, and signifies that all the notes are to be played as smoothly and as much united as possible. In vocal music, it is placed over or under all the notes which are to be sung to the same syllable.

When the slur is placed only over two notes, the second is generally made shorter than its proper length. Formerly, this effect was produced by exact notation.

The dash is a small stroke, placed over those notes which are to be performed in a very short and distinct manner.

The point is a mark employed by many authors instead of the dash; but its principal use is to distinguish those notes from which an intermediate effect, different from the slur or the dash, is required, and yet uniting both.

When these passages are performed on keyed instruments, the finger is not kept close, as in the slur, nor raised, as in the dash, but dropped gently on the note, and taken off before the time is wholly completed.

There are other marks of expression, which have been lately adopted, to express the effect of certain Italian terms.

1. Crescendo, or increasing the sound from soft to loud, is marked by an angle, the lines extending to the right. <

2. Diminuendo, or diminishing the sound from loud to soft, by the contrary sign. >

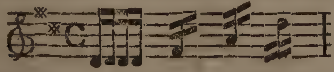
The union of both indicates that the first part of the passage is to be soft, the middle loud, and the last soft again, as the figure shews. <>

3. Rinforzando is denoted by smaller marks of the same kind, > <, which are to increase or diminish the note as marked.

When the same note, or similar passages, are to be repeated, much time is saved to the composer and copyist, by the use of abbreviations.

A single stroke, over or under a semibreve, or through the stem of a minim or crotchet, divides them into quavers; a double stroke into semiquavers; and a triple stroke into demisemiquavers; thus,

(H. S. I. No. 18: "Let the bright seraphim").



These passages, in Italian music, had formerly the word crome (quavers), or semicrome (semiquavers), annexed to them. At present we often use the term segue, to signify that we must perform the following notes in the manner in which the first are marked.

Another kind of abbrevation is very frequently used in modern music, viz. grouping the stems of minims like those of quavers.

Several other species of abbreviation are given in Koch's Lexicon, art. Abkurzung; and also in Clementi, p. 8. Shield, p. 124, &c.

PART II.—MELODY.

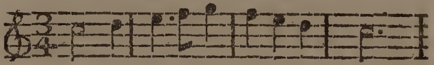
Chap. I.—Of Intervals.

A particular succession of single sounds forms a melody or tune.

Melody has, in respect of tune, two distinct motions; that of degrees, and that of skips.

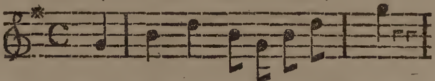
A melody proceeds by degrees, when it moves to the next line or space above or below, as in the following example:

("Let ambition fire thy mind").



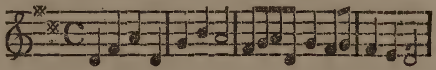
A melody proceeds by skips, when it omits one or more degrees as in the following example:

("When warlike ensigns").



In general, degrees and skips are intermixed; as in the melody of the Easter hymn.

("Jesus Christ is risen to-day").



The degrees and skips of melody are both called by the general term interval; which is the distance between two sounds, or their difference in respect of pitch. Every interval, therefore, implies two sounds, one acute, the other grave; in common language, high and low; and as, in measuring, it is usual to consider the termination of distance more than the space contained; so, in music, the notes which limit the interval, are both called by the name of the interval itself. Thus, from the F clef to the C clef, is contained the interval of a fifth, both terms inclusive; and C is said to be a fifth above F, and F a fifth below C.

The names of intervals are derived from the number of degrees which are contained between the two sounds; both extremes being reckoned inclusively. Thus the interval of a second consists of two degrees; and, as these may be distant from each other, either by one tone, or by one semitone, there are consequently two kinds of seconds, viz. a major second or tone, and a minor second or semitone.

The natural scale of music, which, proceeding by degrees, includes both tones and semitones, is called diatonic; a word compounded of dia and tonic, from the Greek *dia*, through, and *tonos*, a tone; because the greater number of intervals in the scale, viz. five out of seven, are tones.

The diatonic scale includes all the different intervals formed by the natural notes, and also all those which are produced in transposing the natural scale higher or lower, by the employment of sharps and flats. Those intervals which exceed the limits of the octave, as the ninth, tenth, eleventh, &c. being only replicates of the second, third, fourth, &c. are omitted here, but will be particularly noticed in treating of harmony.

Those intervals which are less than the diatonic semitones, as from F to F sharp, &c. will be distributed, with all other intervals derived from them, into proper classes in the third chapter of this part, upon the genera.

As the intervals take their names from the number of included degrees, so also their species are ascertained by the epithets, major and minor, given them, according to the number of tones or semitones contained inclusively between their extremes. If the intervals were all equal in the scale, eight degrees would form only seven intervals; but, as there are two different distances of semitone and tone, for which the notation by the staff alone does not provide, there are consequently fourteen diatonic intervals. These are distinguished by the term major or minor, greater or less, and, in some few cases, sharp or flat.

I. The unison, or the same identical sound, although it cannot properly be reckoned an interval, is always considered as such, when employed in harmony; it is therefore inserted here among the intervals of melody.

II. The minor second is formed by two sounds, at the distance of a diatonic semitone, as B C and E F. C is a minor second higher than B, and B a minor second lower than C. The same is true with respect to E and F. This interval is sometimes called the flat second; and the term is useful in harmony. It is found also in the other scales, between F sharp and G, B flat and A, &c.

III. The major second or tone, although composed of two semitones, does not consist of two equal parts. This is evident from the notation itself; for, if the tone from F to G be divided by the sound F sharp, then the intervals between F sharp and G, or the diatonic semitone, will not be the same as that from F to F sharp, or the chromatic semitone. The former changes one degree, the latter remains on the same degree; and hence the former is, according to the theory of Zarlino, Rameau, and Pepusch, something larger than the latter. The tones and other intervals of the natural scale are, in this work, separated into semitones, &c. by the character called a direct .

IV. The minor third is composed of three degrees, and contains a tone and a diatonic semitone between the two extremes.

It is also divisible into three semitones, two diatonic and one chromatic.

V. The major third is composed of three degrees, and contains two tones between the extremes.

It is also divisible into four semitones, two diatonic and two chromatic.

VI. The perfect fourth is composed of four degrees, and contains two tones and a semitone between the extremes.

It is also divisible into five semitones, three diatonic and two chromatic.

VII. The sharp fourth is composed of four degrees, and contains three tones between the extremes, called by the ancients, on that account, tritone.

It is also divisible into six semitones, three diatonic and three chromatic.

These seven intervals (the unison included) may be considered, in a practical point of view, as primary; since, if they are rightly understood, all the remaining seven are easily known, being only compounded of these. Thus, the fifth is formed by uniting two of the thirds; the sixth, by the fourth and third; the seventh, by the fifth and third; and the octave by the fourth and fifth. Compared with the unison, second, third, and fourth, as primary; the fifth, sixth, seventh, and eighth, are secondary. This arrangement, however useful in the analysis of melody, is imperfect with respect to harmony, and the theoretical classification of the diatonic intervals. The true series comprehends the unison, octave, fifth, fourth, thirds, sixths, seconds, and sevenths, in the mathematical division of a musical string.

VIII. The flat fifth is composed of five degrees, and contains two tones and two semitones (not three tones): it may be divided into two minor thirds.

It is also (like the sharp fourth or tri-tone) divisible into six semitones; and when joined with that interval, completes the octave.

IX. The perfect fifth is composed of five degrees, and contains three tones and one semitone: it may be divided into a major and a minor third.

It is also divisible into seven semitones; and, when joined with the fourth, completes the octave.

X. The minor sixth is composed of six degrees, and contains three tones and two semitones: it may be divided into a minor third and a fourth.

It is also divisible into eight semitones; and, when joined with the major third, completes the octave.

XI. The major sixth is composed of six degrees, and contains four tones and one semitone: it may be divided into a major third and a fourth.

It is also divisible into nine semitones; and, when joined with the minor third, completes the octave.

XII. The minor seventh is composed of seven degrees, and contains four tones and two semitones: it may be divided into a fifth and a minor third; or into two perfect fourths.

It is also divisible into ten semitones; and, when joined with the major second, or tone, completes the octave.

XIII. The major seventh is composed of seven degrees, and contains five tones and one semitone; and may be divided into a fifth and a major third.

It is also divisible into eleven semitones; and, when joined with the minor second, or semitone, completes the octave.

XIV. The octave is composed of eight degrees, and contains five tones and two semitones: it may be divided into a fifth and a fourth.

It is also divisible into twelve semitones, and may be considered as the replicate of the unison; being naturally produced by human voices when a woman or a child endeavours to sound a unison with any vocal tone of a man.

As the octave consists of thirteen sounds, and therefore has only twelve intervals, it must be recollected, that the fourteen diatonic intervals, just described, are obtained by reckoning the unison as one of them, and by distinguishing between the sharp fourth and flat fifth; both which are, upon keyed instruments, performed with the same keys. The seven notes of the scale form seven different species of octave, according to the places of the two natural semitones; and from these species, divided each into two parts, by the fifth or by the fourth, arise the eight tones of Italy, and the twelve modes of Germany.

When the lower note of any interval is placed an octave higher, or the higher note an octave lower, the change thereby produced is called inversion.

Thus a second  becomes a seventh 
a third  a sixth 
a fourth  a fifth 
The different intervals (seven), reckoned from each of the seven natural notes, form the following series:

Five major and two minor seconds.
Three major and four minor thirds.
Six perfect and one sharp fourth.

To these may be added their inversions:

Two major and five minor sevenths.
Four major and three minor sixths.
Six perfect and one flat fifth.

All the major intervals become minor, by inversion, and all the minor intervals become major; the sharp fourth becomes the flat fifth, and the unison inverted becomes the octave.

The major seventh of the key, from its resemblance to the tritone (its higher note being one of the two sounds which form the sharp fourth), is sometimes called the sharp seventh.

Rameau terms the intervals of the third, fifth, and seventh, fundamental; and derives the others, viz. the second, fourth, and sixth, by inversion, reckoning them downward, from the octave of the former.

All these intervals are found in the diatonic or natural scale; and, when this scale is transposed to any other pitch, higher or lower, by the use of sharps or flats, these intervals remain the same, as will be more fully seen hereafter.

Of all the diatonic intervals, the two thirds, major and minor, are by far the most important, and ought to be very perfectly understood; since upon them depends the nature of the scale or mode; and the thirds give their own epithets to the whole series of the seven notes, the scale itself being called major, when the third is greater, and minor, when the third is lesser.

There is another distinction, in respect of melodies formed of diatonic intervals, which, although in some measure obsolete, is yet useful for the student to understand. Those melodies which have their principal notes contained between the key-note and its octave are termed authentic direct, or principal.

Those melodies, on the contrary, which have their principal notes contained between the fifth of the key and its octave (or twelfth), are termed plagal, oblique, or collateral.

By these two divisions of the octave, authentic and plagal, are formed the arrangements of the eight Italian tones, and twelve German modes, before-mentioned.

Chap. II.—Of consonant and dissonant Intervals.

Although the terms consonant and dissonant are chiefly used in harmony, yet they are applicable, in a great measure, to the classing of intervals in melody.

The diatonic intervals are therefore divided into consonant and dissonant. Those which are most agreeable to the ear, as the octave, fifth, fourth, both the thirds, and both the sixths, are called consonant; those which, when compared with the others, are less agreeable to the ear, as both the seconds, both the sevenths, with the sharp fourth, are called dissonant.

The term dissonant is thought, by some authors, inapplicable to the degrees of melody which seem more natural to the human voice than the skips. This, however, is a prejudice, which a further consideration of harmony will remove.

The foregoing arrangement shews the propriety of distinguishing the species of seconds, thirds, sixths, and sevenths, by the epithets major and minor, according to the number of semitones included between the extremes; while the appellation of perfect is reserved for the fourth and fifth with the terms sharp and flat, when altered a semitone higher or lower.

The thirds and sixths, whether major or minor, are always consonant; the seconds and sevenths always dissonant; but the fourth and fifth are consonant only when perfect; when sharp or flat, they are dissonant. The alteration of these two last intervals, therefore, places them in different classes; and, although the terms major and minor have sometimes been applied to the fourth and fifth, in the present work those terms will not be used.

The consonant intervals are subdivided into perfect and imperfect. The unison (or prime), the octave, fifth, and fourth, are called perfect, because they are immutable, never changing from major to minor (or the contrary), but becoming dissonant whenever altered by a sharp, flat, or natural.

The thirds and sixths are called imperfect, because they are liable to change from major to minor (or the contrary), still remaining consonant.

The seconds, sevenths, sharp fourth, flat fifth, with all the chromatic and enharmonic intervals, are dissonant.

According to this classification, every passage of melody which moves by degrees, consists of dissonant intervals; but, as every other note is, in general, a transient sound, placed between two consonant notes, these seconds have not that harshness which is found in the passages which move by skips, as the sharp fourth, flat fifth, minor and major sevenths, &c.

All dissonant seconds in melody, are either passing or changing notes; and these are either regular, when found on the weak parts of the measure, or irregular, when used on the strong parts. If, therefore, these ornamental notes are taken away, a series of consonant intervals will remain.

A successive series of perfect fifths is not to be found in melody, and hence is forbidden in harmony. In melody, they would exceed the limits of our regular scale, as well as the compass of the voice; and, in harmony, they would produce new and unconnected scales, of which the species, major and minor, would be undetermined, through the omission of the thirds and sixths.

Chap. III.—Of the Genera.

That scale of music which proceeds chiefly by tones, called diatonic, has been explained, and constitutes the principal part of every piece of music.

When all the artificial sounds are inserted between the natural sounds, a scale is formed of semitones alone, and called chromatic.

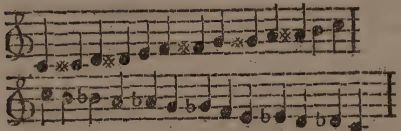
When a scale yet smaller in its intervals is formed, which contains in some places quarter-tones, it is called enharmonic.

These three scales, the diatonic, the chromatic, and the enharmonic, form the three genera or kinds of melody now in use; and, although the terms are borrowed from the Greek authors, yet the modern ideas annexed to them are considerably different from their ancient signification.

The origin of the term diatonic genus has been explained. The chromatic takes its name from the Greek word chroma, colour, because the interspersed semitones give an ornamental effect to the diatonic or simple melody; and the enharmonic was so called, from its supposed excellence, being en-harmonic, that is, extremely musical.

The two last genera (chromatic and enharmonic) are never used alone, but always intermixed with the diatonic. Hence it has been asserted, that all the genera, except the diatonic, are irretrievably lost. That they are lost to us, in the precise sense of the ancient descriptions, is undoubtedly true; but we still retain the term chromatic, in a signification extremely analogous to its primitive meaning, and it seems proper also to retain the terms diatonic and enharmonic.

The chromatic scale generally ascends by sharps, and descends by flats, as in the following example:



From this scale several intervals, not yet described, arise, which are all discordant, and are chiefly used in melody, although they appear sometimes, by licence, in harmonical combinations.

The chromatic scale consists of thirteen sounds, which contain twelve intervals between them. Seven of these have been already described, among the diatonic intervals; the remaining five form another species of intervals, called extreme or chromatic. Of these, the chromatic semitone, the extreme sharp second, flat third, and flat fourth, are simple or primitive; the extreme sharp fifth, sharp sixth, flat seventh, and flat eighth, are compound or derivative.

I. The chromatic semitone is the distance or interval between any note, and that same note elevated by a sharp, or depressed by a flat.

This semitone was termed by the Pythagoreans apotome, and the diatonic semitone was termed limma. They contended, that the apotome, or distance from B flat to B natural, was larger than the limma, or distance from A to B flat. It is now, however, demonstrated, by the experiments of Mersenne, &c. &c. that the theory of Zarlino and Salinas is true; namely, that the interval from A to B flat is the major semitone, and that from B flat to B natural is the minor semitone, contrary to the nomenclature of Boethius and the Pythagoreans.

In the chromatic scale, the semitones are alternately chromatic and diatonic; and, as there are only five of the former, while there are seven of the latter, two diatonic semitones will be found in succession, at the place where the natural semitone occurs.

From this important interval (the chromatic semitone) arise all the other chromatic intervals: they are all diatonic distances, increased or diminished by this interval; and hence they all take the additional chromatic epithet of extreme.

II. The extreme sharp second consists of a tone and a chromatic semitone, being composed of two degrees. Upon keyed instruments, this is the same as the minor third; which, however, consists of a tone and a diatonic semitone, and therefore contains three degrees.

III. The extreme flat third consists of two diatonic semitones, being composed of three degrees; and is the minor third, diminished by the chromatic semitone. Upon keyed instruments, this is the same as the tone, which contains only two degrees.

IV. The extreme flat fourth consists of a tone and two diatonic semitones, being composed of four degrees; and is the perfect fourth, diminished by the chromatic semitone. Upon keyed instruments, this is the same as the major third, which contains only three degrees.

These three last intervals, viz.

The extreme sharp second, the extreme flat third, and the extreme flat fourth, when inverted, become the following: the extreme flat seventh, the extreme sharp sixth, the extreme sharp fifth.

V. The extreme sharp fifth is the perfect fifth, increased by the chromatic semitone, and consists of four tones, forming five degrees. On keyed instruments it is the same as the minor sixth, which consists of six degrees. This interval is seldom found in melody; but its inversion, the extreme flat fourth, is generally taken in its place. It is also divisible into two major thirds.

VI. The extreme sharp sixth is the major sixth, increased by the chromatic semitone, and consists of five tones, forming six degrees. On keyed instruments it is the minor seventh, which consists of seven degrees.

It is also divisible into a major third and sharp fourth.

VII. The extreme flat seventh is the minor seventh, diminished by the chromatic semitone, and consists of four tones and two diatonic semitones, forming seven degrees. On keyed instruments it is the major sixth, which only consists of six degrees. It is also divisible into three minor thirds.

VIII. The extreme flat eighth is the octave, diminished by the chromatic semitone: it is never used in melody, but is sometimes found in transient passages of harmony.

When a series is formed by uniting the ascending with the descending scale of the chromatic genus, a new kind of music arises, by the use of the interval formed between the sharpened note and the flat of the next succeeding note above. This scale is called enharmonic, and contains intervals smaller than the semitone; which, although not exactly half the semitone, are, however, from their near approach to that quantity, called the diesis (that is, the division), or quarter tone.

To form this interval, it is necessary that, of any two notes which are distant by the tone, the highest should be depressed, and the lowest elevated, by the chromatic semitone. Thus, from G to A is a tone. Now, if G sharp be taken instead of G, and A flat instead of A, the difference between these extremes of the two chromatic semitones, G sharp and A flat, will form the enharmonic diesis, or quarter tone.

To understand this, it must be observed, that the interval of a tone, in the theory of harmonics, is not always the same. That tone which is between the fourth and fifth of the scale, is supposed to be divided into nine small parts, termed commas; while that which is between the fifth and sixth of the major scale, is divided only into eight commas. The diatonic semitone consists of five commas, and the chromatic semitone of three, or four, according to the magnitude of the tone.

The two chromatic semitones, therefore, being taken from the minor tone (of eight commas), leave a residue of two commas for the diesis or quarter tone: hence on the Temple organ, and on some other instruments, the tones from G to A, and from D to E (which are naturally minor, or of eight commas), are divided into three parts, by two distinct keys, one for G sharp, another for A flat; also one for D sharp, and another for E flat. But upon keyed instruments, in general, the temperament, or method of tuning, is such, that the single short key between the two longer keys serves for both purposes, that between G and A being turned higher than G sharp, and lower than A flat.

The enharmonic scale divides each tone into two chromatic semitones and the quarter tone; thus,

In some examples of the enharmonic scale, the intervals, F flat and E sharp, as also C flat and B sharp, are inserted; but they do not belong to that scale. This distance, as Dr. Pepusch observes, is smaller than the quarter tone.

This arises from the division of the diatonic semitone into two quarter tones, and a smaller interval, termed the hyperoche, which is found by theoretical calculation to be nearly a comma and a half.

Such are the three modern genera, the diatonic, chromatic, and enharmonic.

Chap. IV.—Of Keys or Scales, and of their two Modes, major and minor.

A diatonic scale, of which the notes bear certain relations to one principal note from which they are all, in some respects, derived, and upon which they all depend, is termed a key; and the principal note is called the key note, or tonic.

Every scale in which the two diatonic semitones are found between the third and fourth degrees, and between the seventh and eighth degrees, ascending from the tonic, is termed the major mode of that key; because the interval between the tonic and its third (or mediant), consists of two tones; that is, of the greater third. The only series of this mode among the natural notes, is that which commences with C; and hence this key must be taken as an example of all the major scales.

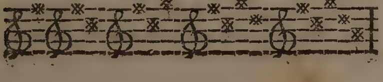
Every scale in which the two diatonic semitones are found between the second and third degrees, and between the fifth and sixth degrees, as ascending from the tonic, is termed the minor mode of that key; because the interval between the tonic and its third (or mediant), consists only of one tone and one semitone, that is, of the lesser third. The only series of this mode among the natural notes, is that which commences with A; and hence this key may be taken as an example of all the minor scales. See KEY.

We have already shewn how the introduction of sharps changes the pitch of the tone, without altering the relative intervals of the scale. All the other major keys with sharps are constructed in the same manner, viz. by sharpening the fourth of the former key, to make a new sharp seventh, or leading note, to the following scale.

It has been also shewn that the introduction of a new flat takes place on the seventh of the original key, which then becomes the subdominant or fourth of the next scale: hence are formed scales with flats.

When the whole number of sharps and flats are placed at the clef, instead of being occasionally inserted before each note as they occur, such collection of sharps, or of flats, is termed the signature.

Signatures of scales with sharps.



Signatures of scales with flats.

The scale of F sharp with six sharps, being the same on keyed instruments as that of G flat with six flats, all the signatures beyond six may be expressed by a smaller number, by changing the name of the tonic.

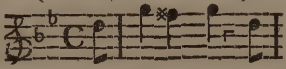
Thus C sharp with seven sharps, is the same as D flat with five flats; and C flat with seven flats, is the same as B with five sharps, &c. &c. &c.

The minor scale not only differs from the major, as before observed, in the place of its semitones, but also in the variation of its scale, of which the ascending series differs from the descending one.

The minor mode requires, that whenever the seventh of the scale (which is naturally a tone below it) ascends to the eighth, it should become sharp, as the proper leading note or sharp seventh to the tonic. Now, the insertion of this essential note in the signature, would appear irregular; it is therefore always omitted in the signature, and placed accidentally before the seventh which it is to elevate, whenever the melody requires its use.

That this leading note or sharp seventh is essential to the key, although not to its signature, may be proved by performing the subsequent melody, omitting the sharp F.

("Our fears are now.")



In which instance, the harshness produced by F natural, if taken instead of F sharp, is extremely perceptible.

As the signature, therefore, does not decide the key or scale of the movement, a careful observation must be made, whether any accidental sharps or naturals occur in the first phrase or section. If any such are found, the tonic is on the next degree above them; but, if none are used, then the signature itself determines the major tonic, which is always the note above the last sharp, or the fourth note below the last flat.

The accidental sharp used in the minor mode raises the minor seventh of the scale a chromatic semitone: hence the minor scale may be said to belong to the chromatic genus.

The minor scale whose tonic is found on the sixth note ascending of that major scale which has the same signature, is termed the relative minor, because its signature is similar to that of the other.

These tonics, it may be observed, are one degree below the last sharp of the signature.

In the signatures with flats, the relative minor (or sixth of the key) is always on the third degree above the last flat.

Every major scale, when its third and sixth are depressed by the chromatic semitone, becomes a minor scale on the same key note, and will be called the tonic minor.

But, as the signature requires that the essential sharp seventh should not be inserted at the clef, the tonic minor must have in its signature another flat, making in all three flats more, or three sharps less, than the major scale of the same key note.

That change which arises from the performance of the same melody in a higher or lower pitch, is called transposition.

Every melody in a major scale may be transposed into any other major scale, by altering the signature according to the pitch of the new tonic. The same alteration may take place in every minor melody. When, however, any tune is performed in the relative, or in the tonic minor, which tune was originally major, such change is not called transposition, but variation.

When, in the course of a melody, the tonic is changed, and the original scale altered, by the introduction of a new sharp or flat, such change is called modulation. This will be further explained in treating of harmony.

Every scale has two others immediately connected with it; one on the fifth above, which adds a new sharp to the signature; the other on the fifth below (or fourth above), which adds a new flat to the signature. These two scales are called attendant keys; an epithet given them by Dr. Boyce, in his manuscripts.

As every major key has a relative minor, and as this relative minor has its two attendant keys, hence arise, from every signature, six scales, nearly connected with each other: three with major thirds, and three with minor thirds.

Of these, two are principal, viz. the major and minor of the signature itself; and four are subordinate, viz. the attendant keys, both of the major and of the minor: these require another sharp or flat, to complete their scales, when a modulation occurs.

Thus, in the major scale of C, its attendant scales are G (its fifth), with one sharp, and F (its fourth), with one flat; to which are annexed the relative minor A, and its two attendant scales, viz. E minor with one sharp, and D minor with one flat.

The same arrangement takes place in every key; and it is necessary to observe, that when the minor key is first taken, the major key of the same signature is called the relative major, and is found on the minor third above the original minor key-note.

Chap. V.—Of the Qualities of the Notes which compose the Scale.

Every one of the seven notes which form the scale of any key, major or minor, has an effect peculiar to itself: from this effect they derive particular names, which are these.

I. The tonic, or key-note, before described is that chief sound upon which all regular melodies depend, and with which they all terminate. All its octaves, above or below, are called by the same name.

II. The dominant, or fifth above the key-note, is that sound which, from its immediate connexion with the tonic, is said to govern it; that is, to require the tonic to be heard after it, at the final perfect cadence in the base.

III. The subdominant, or fifth below the key-note, is also a species of governing note, as it requires the tonic to be heard after it in the plagal cadence. It is the fourth in the regular ascending scale of seven notes, and is a tone below the dominant; but the term arises from its relation to the tonic, as the fifth below.

These three principal sounds, the tonic, dominant, and subdominant, are the radical parts of every scale; of the minor, as well as of the major. All melodies whatever are derived from these sounds, and are wholly dependent upon them.

IV. The leading note, or sharp seventh of the scale, is called, in Germany, the subsemitone of the mode. This is always the major third above the dominant, and therefore, in the minor scales, requires an accidental sharp or natural, whenever it occurs.

V. The mediant, or middle note between the tonic and dominant ascending, varies according to the mode; being the greater third in the major scale, and the less third in the minor scale.

VI. The submediant or middle note between the tonic and subdominant descending, varies also according to the mode, being the greater sixth in the major scale, and the lesser sixth in the minor scale.

VII. The supertonic, or second above the key-note, has seldom been distinguished in England by this or any other appellation. In theory it is considered as a variable sound, being a comma higher in the major scale than when the mode changes to the relative minor.

The leading note and the subdominant are the two characteristic sounds, by one of which every scale, whether major or minor, is known, and its tonic immediately ascertained.

Thus, in sharp signatures, the leading note is a species of index, which points invariably to the next degree above, as its major tonic: this is always the last sharp in the major mode.

In flat signatures, the subdominant is also a species of index, which points to the fourth degree below, as its major tonic: this is always the last flat in the major mode.

In the minor modes whose signatures have less than four sharps or four flats, the subdominant, being always one of the natural notes, is not apparently a characteristic of the key; and therefore, in those modes, the leading note is the only certain index from which the key-note is to be found.

The great importance of these two notes appears evident, when, in occasional modulation, the new key is required to be found by their assistance. In all flat signatures (F major, B flat major, E flat major, &c.) the leading note is a natural; and this is the sharp seventh of the key.

In the sharp signatures, on the contrary, the subdominant is distinguished by a natural, and requires, in modulation, the alteration of the sharp in the signature.

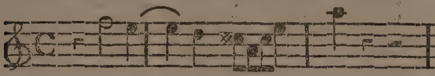
Hence it appears, that whenever the characteristic note of the new key is marked by a natural that natural always has the effect of a sharp, or of a flat; of a sharp, when it is a leading note; of a flat, when it is a subdominant.

In the music of Corelli, Geminiani, Handel, &c. the general rules of finding the tonic, either in the major mode, by the characteristic notes of the signature, or in the minor mode, by the leading note accidentally inserted, are not always sufficient.

When, instead of the complete series of sharps or flats of the signature, the last sharp or flat is suppressed, and inserted accidentally when requisite (like the leading note of the minor mode), such deviation from the usual method of notation will, in this work, be termed the ancient signature.

Thus, in the seventh and twelfth sonatas (or violin solos) of Corelli, opera quinta, the signatures appear to be either C major, or A, its relative minor; but the accidental notes, C sharp and B flat, shew that the real key is D minor, and that the B flat, which is used in the modern signature, is omitted at the clef.

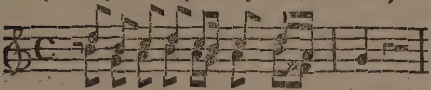
Examples of the ancient signature of D minor may also be found in the third and fifth concertos of Geminiani, opera seconda, and in the fourth concerto of opera terza. For instance, the first movement of his third concerto begin thus :



Here the key is known to be D, by the accidental C sharp, and to be also D minor, by the natural F, which remains unaltered, as in the signature.

The same ancient method of notation is sometimes found in the key of G major, where the sharp of the leading note F, is inserted accidentally when requisite; as in the following example from the first chorus of Handel's Oratorio of Saul, How excellent thy name, O Lord. One of the intermediate movements commences thus :

("The youth inspired by thee, O Lord.")



Here the key is known to be G by the sharp before the F, which is used in the second treble as a third below the A; and the B natural of the clef shews it to be G major.

Part III.—Harmony.

Chap. I.—Of the Triad.

Two or more melodies, heard at the same time, form harmony; and the different combinations of notes in harmony are termed chords.

The union of any sound with its third (major or minor) and its perfect fifth, forms the harmonic triad, or common chord.

This is termed the major or minor triad, according to the nature of its third.

When the octave of the lowest note is added, four sounds are heard in the harmony.

There are also, besides these two consonant triads, two dissonant triads; one diatonic, the other chromatic.

I. The diatonic dissonant triad, or diminished triad of the Germans (B, D, F) consists of two minor thirds.

II. The chromatic dissonant triad, or superfluous triad of the chromatic scale (C, E, G sharp), consists of two major thirds.

The consonant triads are formed of the two dissimilar thirds, major and minor, united; the dissonant triads are formed of two similar thirds, both minor or both major.

In the natural diatonic scale there are six consonant triads; three major and three minor.

All the major triads become minor, by flattening their thirds; and all the minor triads become major, by sharpening their thirds; thus,

The diatonic dissonant triad has (by licence) its third sometimes flattened and sometimes sharpened; and thus are formed two altered triads, which are very seldom used.

These altered triads consist of a major and an extreme flat third, and are consequently both chromatic.

The prime, or lowest note of the triad, was called by Rameau its fundamental base. In this work, the term radical base, or simply the root, will be adopted.

The roots of the two consonant triads are easily understood, as every radical base must have a perfect fifth; but the roots of the two dissonant triads and of the two altered triads cannot be explained till the nature of discords is known.

When the three sounds of the triad are taken as an accompaniment, and the root remains in the base, the chord assumes three different positions.

The first position is that of 3d, 5th, and 8th.

The second, of 5th, 8th, and 3d.

The third, of 8th, 3d, and 5th.

It must be observed, that the second position, in reality, consists of the fifth, eighth, and tenth, and the third position, of the eighth, tenth, and twelfth of the root; but, as the tenth and twelfth are octaves of the third and fifth, and as they are represented by the same letters, they are also called by the names of third and fifth, whatever may be their distances above the root.

When the lowest note, instead of being the root, is the third or the fifth of the triad, such change is termed inversion.

The inversions of the triad differ from its positions; as the former relate to the whole harmony, including the base, and the latter to the accompaniment alone, independent of the base. Hence every triad has three positions, but only two inversions; for, when the root is in the base, the chord is called direct, whatever may be the positions of the accompaniment.

I. The chord of the sixth, is the first inversion of the triad, when the base note becomes the third of the harmony, instead of the root. This chord, in the figures of thorough base, is expressed by a 6; to which also belongs the third of the lowest note (or fifth of the root); and, in the practice of counterpoint, the octave of the lowest note is either omitted, or, if four parts are requisite, the sixth or the third may be doubled.

The same arrangement takes place in the minor triad, and its first inversion: in the first inversion of the diatonic triad, B, D, F, however, the sixth is never doubled, but the octave preferred, when four parts are requisite.

A stroke through the figure six, thus 6̸, elevates the sixth note from the base, a chromatic semitone, and when used on a minor sixth, makes it the first inversion of the dissonant triad.

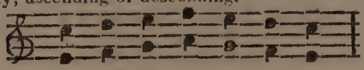
When the same mark occurs on a major sixth, it makes it the first inversion of the altered triad.

These two chords, which are of great importance, will be hereafter distinguished by the names of the sharp sixth and of the extreme sharp sixth; the first always accompanied by a minor, and the second by a major third.

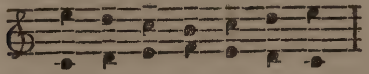
II. The chord of the fourth and sixth, is the second inversion of the triad, when the base note is the fifth of the harmony, instead of the root. It is expressed, in thorough base, by a 4 under a 6, and, in four parts, the three positions of the triad are used as its accompaniment without any regard (as in the chord of the sixth) to the omission of one note, or the doubling of another.

Before the harmonical succession of triads can be rightly understood, it is necessary to explain the different motions of the parts which constitute harmony. Two of these are essential, viz. the direct motion and the contrary motion.

In the direct motion, the parts move the same way, ascending or descending.



In the contrary motion, one part rises, while the other falls.



By the knowledge of these two motions, the power of avoiding many harmonical irregularities may be obtained, and the following rules of harmony correctly observed.

I. All consecutive octaves and fifths must be avoided in the direct motion.

II. All unnecessary skips are to be avoided, and all the chords are to be taken as closely and as much connected as possible.

III. All false relations (such as the extreme sharp second, &c.) are disallowed, unless for the expression of some particular effect.

IV. All irregular motions of the parts in harmony are to be avoided. Every major or sharp interval ought to ascend, and every minor or flat interval ought to descend; that is to say, the part in which those intervals are found in combination, is to rise after the sharp, and to fall after the flat. This rule, however, is always subordinate to that of avoiding octaves or fifths, and is not regarded when the melody is to produce an effect opposite to the rule. The internal parts of harmony, however, are to be regulated by these observations.

Of harmonical progressions.—The term progression will be used, in this work, in contradistinction to the term modulation, to signify that succession of triads or perfect chords, which, by being confined to the scale of the original key, only admits the tonic and its two attendant harmonies, occasionally interspersed with the relative tonic and the two harmonies attending on that scale; whether the original mode be major or minor.

Although a change into the relative scale implies a partial modulation, yet in all cases, where the new scale remains undecided, by the omission of the leading note, and the original tonic still continues a predominant sound, the term progression will be retained.

As the scale consists of seven different notes, it is evident that two triads, which only contain five notes (one note being common to both), cannot decide the key.

If, however, three different chords are taken, the key may be decided: this is performed by the progression of tonic, subdominant, and dominant.

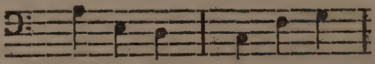
Thus, in the tonic harmony, are found the 3d and the 5th
In the subdominant, the 4th and 6th
And in the dominant, the 2d and 7th
} of the root of the scale.

The major mode, with its relative minor, and the four attendant harmonies, may be thus arranged:

Tonic. Domt. Subdt. Rel. Min. Its Dt. Its Subdt.

The minor mode, with its relative major, and the four attendant harmonies, may be thus arranged:

Tonic. Domt. Subdt. Rel. Maj. Its Subdt. Its Dt.



The motions of the radical bases or roots of these chords, are reducible to six, divided into three classes.

I. The dominant motion, or ascent of the 4th or fifth.

II. The mediant motion, or ascent of the 3d or 6th.

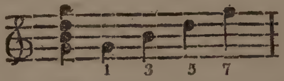
III. The gradual motion, or ascent of the 2d or 7th.

These may, of course, be inverted, and become the same descending.

Of these motions, the dominant and the mediant are regular, having a sound common to both chords; but the gradual is irregular, as the chords have no connexion with each other.

Chap. II.—Of the dominant Seventh, its Inversions, Resolution, and of Modulation.

When a minor seventh is joined to the major triad, a chord of four different sounds is formed, and, as this only occurs when the fifth of the key is the base note, the harmony is called the dominant seventh.



The note which forms the discord in this harmony, is the subdominant or fourth of the scale; and, being a minor interval, requires the part in which it is heard, to descend one degree.

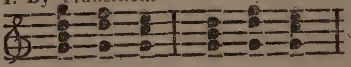
In the major mode, this descent is a semitone.

In the minor mode, the E becomes flat, and the descent is consequently that of a tone.

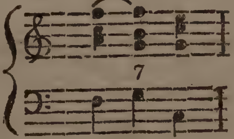
The major third of the dominant, which is also the sharp seventh or leading note of the scale, must ascend. Thus, in the major scale, the two characteristic notes are united, and form, between themselves, the interval of the flat fifth, of which the root is the dominant.

The dominant seventh is used, like all other discords either by transition, addition, or suspension; and must in all cases be resolved, that is, taken away, by the descent of the part in which it is found. As a passing or added note, it is employed without preparation; thus,

I. By Transition. II. By Addition.



But, as a suspended note, it must be prepared, that is, heard in the preceding harmony; thus,



In this instance, the F prepares the seventh in the first harmony; is heard as a discord in the second, and resolves, by descending to E, in the third.

There are several other sevenths, used in harmony, upon the different triads of the scale (whether consonant or dissonant), in both modes. These sevenths, although not exactly chords of the dominant, are nevertheless used in its place, to avoid modulation. They also preserve a uniform motion in the progression of their roots, and, at the same time, produce a melody, descending by degrees, in the original key. These are,

I. The minor sevenths with minor thirds, on the triads of A, D, and E, which belong to A minor.

II. The major sevenths with major thirds, on the triads of C and F, which belong to C major. These are often found in passages of transition.

III. The minor seventh with the flat fifth, upon B.

IV. The extreme flat seventh, upon G sharp in A minor, formed of three minor thirds.

The seventh, consisting of four sounds, admits of four different positions.

The first position is that of 3d, 5th, 7th, and 8th.

The second, of 5th, 7th, 8th, and 3d.

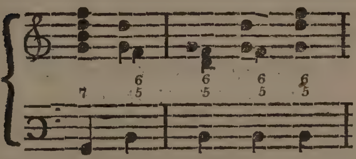
The third, of 7th, 8th, 3d, and 5th.

The fourth, of 8th, 3d, 5th, and 7th.

These positions, like those of the triad, contain the tenth, twelfth, and fourteenth of the root, when the third, fifth, and seventh, are taken above the octave.

This harmony, which consists of four different sounds, has, consequently, three inversions, besides its direct form of 3d, 5th, and 7th, just described.

I. The chord of the fifth and sixth is the first inversion of the dominant seventh, when the lowest note becomes the third of the root. In thorough base it is expressed by a 5 under a 6 (to which the third is understood), and, in practice, the octave of the base note is omitted.



II. The chord of the third and fourth is the second inversion of this harmony, when the lowest note becomes the fifth of the root. It ought, according to its derivation, to be expressed by a 3 under a 4 (to which the sixth is understood); but, as the fourth (or proper root of the harmony) is not pleasing to the ear, it is usually omitted. Thus, the chord appears as a simple sixth, and also as the first inversion of the diatonic dissonant triad, D, F, B.

III. The chord of the second and fourth is the third inversion of this harmony, when the lowest note becomes the discord, and the triad commences on the next degree above. It is expressed by a 2 under a 4 (to which the 6th is understood), sometimes by a 2 alone.

The descent of the part in which the dominant seventh is found, is called its resolution; and, as before observed, that descent is either a tone or a semitone, according to the mode.

This resolution of the seventh occasions two apparent irregularities, viz.

I. The four sounds of the dominant, followed by the three of the triad; in which the last harmony is weakened by two parts becoming unison.

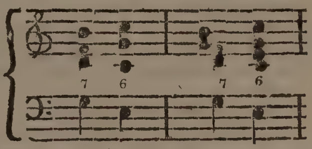
II. The omission of the fifth in the tonic triad, when the antecedent dominant is taken without the octave to the base.

When, however, instead of the octave, the fifth or third of the dominant itself is omitted, the subsequent triad can be taken complete.

Two classes of instances occur, when this general rule of resolving the seventh by the descent of the melody is apparently neglected.

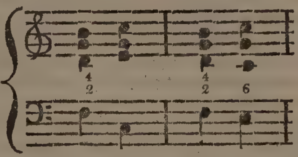
I. When, by licence, the base itself takes the resolution;

Thus, instead of



II. When, after the third inversion, the base, instead of descending a semitone, descends a fourth to the tonic, and another part takes the resolution;

Thus, instead of



Not only the positions of the dominant seventh may be changed, but the inversions also may succeed each other, previous to its resolution. Great care however must be taken, in the arrangement of the parts, to prevent transgressing the rules before given.

I. The first inversion, or chord of the fifth and sixth, resolves by the base ascending a semitone.

II. The second, or chord of third and fourth, resolves by the base descending a tone.

III. The third, or chord of second and fourth, resolves by the base descending a semitone.

The other sevenths when used in sequences, have similar inversions; and the same method of resolution is generally applicable to them all.

As all changes of key are known decidedly by the use of the dominant seventh, the different modulations from both scales will be now explained.

Modulation from the major scale.—I. To the scale of its subdominant. The principal, and most simple change of key, is that which, by adding a minor seventh to the tonic, makes it a new dominant; and hence the subdominant becomes a new tonic. This modulation being continued, forms a circle of descending fifths, or ascending fourths.

II. To the scale of its dominant. The second change is that which, by retaining the octave of the tonic itself, as a seventh, and by making the base ascend a tone in gradation, descends from the supertonic to the original dominant. This modulation being continued, forms a circle of descending fifths, or ascending fourths.

These two modulations are in continual use; the last, or dominant change, in the former part of a movement; and the first, or subdominant change, towards the conclusion, to restore the original tonic. The subdominant modulation only requires two roots, but that of the dominant requires three.

III. To the scale of the submediant or relative minor. The third change is that in which the base rises from the tonic to the mediant; and, making that a new dominant, by the addition of the seventh, descends to the relative minor tonic.

A similar modulation being continued, forms a circle of keys, in which the major and relative minor succeed each other alternately.

This modulation requires four roots, previous to the alteration of its signature; but the sudden addition of the seventh (especially after the minor tonic), is rather harsh and unexpected.

IV. To the scale of the mediant, or relative minor of the dominant. The fourth change is that which, through a previous modulation into the dominant, makes the original mediant a tonic.

V. To the scale of the supertonic, or relative minor of the subdominant. The fifth change is that which, by making the submediant a dominant, forms a new scale on the supertonic.

Modulation from the minor scale.—I. To the scale of its subdominant. The principal change, like that in the major mode, is made by adding a seventh to the tonic, and sharpening its third, to form a new dominant.

II. To the scale of its dominant. The second change requires an additional harmony (borrowed from the sequence of sevenths) to alter its signature, previous to the use of the new dominant.

III. To the scale of its mediant or relative major. The third change is made by the reversed gradation, or the descent of a tone.

IV. To the scale of its submediant. The fourth change adds a seventh to the mediant, as in the minor modulation before given.

V. To the scale of its seventh. The fifth change, which is very unusual, is made from the original subdominant with a major third.

Modulations are continually formed from one scale to another, by means of tonic harmonies alone; but, in those instances, it is proper to introduce the new dominant as soon as possible, to decide the key; otherwise, the equivocal effect before adduced would frequently occur.

Chap. III.—Of Discords.

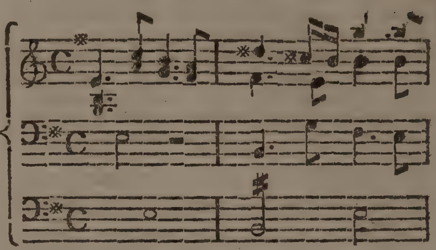
Discords are used in harmony, either by transition, suspension, syncopation, or addition.

Discords of transition.—Any note which passes by one degree between the other notes of the triad, forms a discord of transition, and, if found on the weak part of the measure, is termed a passing note.

The notes of irregular transition are found on the strong parts of the measure, and are called by the Germans changing notes.

In the following example, a particular instance of irregular transition occurs.

(Overture to the Messiah.)



The last note but one (viz. the F sharp) is here taken as a discord by irregular transition, which the radical base placed below demonstrates.

In modern music, all the discords of transition may be reduced to appoggiaturas or after-notes.

When the notes of transition are prolonged, they appear as integral parts of the harmony, and are sometimes marked with the figures of thorough base.

Discords of suspension.—I. Of the fourth. The fourth, accompanied with the fifth, and eighth, is an appoggiatura, continued in the place of the third, on the strong part of the measure. It is generally prepared, and is resolved by descending one degree.

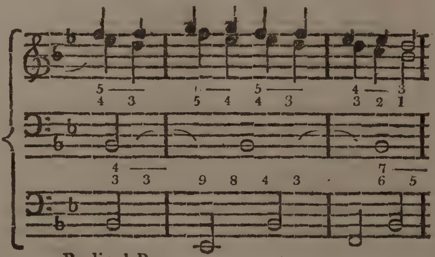
It has two inversions, viz. the second and fifth, which suspends the sixth and the fourth and seventh, which suspends the fourth and sixth, the two inversions of the triad.

II. Of the ninth.—The ninth, accompanied with the third and fifth, is an appoggiatura, continued in the place of the eighth. It is, like the fourth, generally prepared, and always resolved.

The chord of the ninth has two inversions; one figured with a seventh, followed by its resolution the sixth, on the third of the root; the other figured as fifth and sixth, on the fifth of the root.

The following tonic pedal or organ-point is a very important study for the chords of suspension.

(" O the pleasures of the plains").



Radical Base.

III. Of the appoggiaturas of suspension.—Although every note of suspension may be reduced to an appoggiatura, yet, in modern music, some notes are more particularly used as such than others, and differ from those just described by greater freedom in their resolution.

Any part of the dominant seventh may be retained on the tonic base, and afterward proceed according to its proper motion.

The ninth also may resolve by ascending into the tenth, and the sharp seventh (or leading note) must resolve by ascending into the eighth.

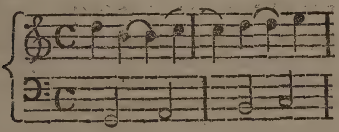
In this ascending resolution of the dominant seventh, the figure of the suspended ninth often becomes a second.

In diatonic sequences, as will be shewn hereafter, every note of the scale may bear single or double suspensions.

All these notes are nothing more than the retardation or retention of a sound, longer than the duration of its own root, upon a new radical base.

IV. Of anticipation, &c.—When a note is diminished by half its value, and the following degree employed to fill up its time upon the former base, such change is termed anticipation. These anticipated notes are considered wholly as relating to melody, and are not noticed by the figures of thorough base.

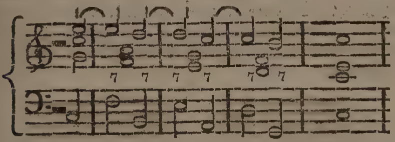
The postpositions of Dr. Pepusch are in reality nothing more than irregular suspensions, being the reverse of the anticipation, and used in the following manner:



Many other chords of suspension may be formed, by combining all the preceding in different ways. Hence arise the second and third, the sixth and ninth, &c. &c.; which may be found in Kirnberger, Kollmann, Shield, &c.

The discords of syncopation only differ from those of suspension by constituting part of the radical harmony, and by not being merely appoggiaturas.

The diatonic sequence of sevenths is one of the principal passages in which these discords are used.



The German authors, previous to the writings of Kirnberger (1774), seem to have classed the discords of suspension with those of syncopation; but his arrangement of chords, into essential and accidental, establishes that difference between them which is here adopted.

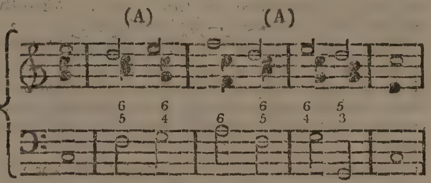
When any discord which has not been heard in the preceding harmony is united to the perfect triad, it is termed in this work a discord of addition.

The discords of addition are the seventh, the ninth, both on the dominant; and the sixth on the subdominant; these are particularly useful in distinguishing those two harmonies from that of the tonic.

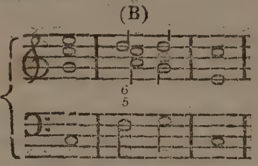
I. Of the added seventh. The whole second chapter of this part relates to the dominant seventh.

II. Of the added sixth. As the dominant harmony is distinguished from that of the tonic by its added seventh, so the subdominant is distinguished from the tonic, and from the dominant, by its added sixth.

Whenever the melody of a single part (as at A,) or the harmony of the whole (as at B), requires it, the subdominant may have its own sixth (or supertonic of the scale) added to its triad.



Sixth added for the melody.



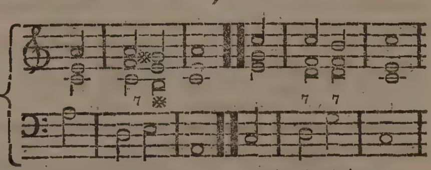
Sixth added for the harmony.

The fifth and sixth on the subdominant may be prepared by the tonic, by the submediant, or by the dominant, as radical bases.

This discord may resolve two ways, viz. into the tonic (on its second inversion), or into the dominant harmony.

When this harmony appears in the form of a seventh on the supertonic, it frequently constitutes part of the diatonic sequence of sevenths, and, as such, may be accounted radical, like the diminished triad of Kirnberger.

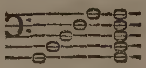
Rameau estimates the root of this harmony by its resolution, calling it D when followed by G, and F when followed by C. Heck considers it as a compound of both the harmonies of D and F. Dr. Boyce (in his MSS.), and with him Dr. Calcott thinks, that the root is decided by the scale of the key in which it is found; thus,



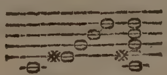
D in A Minor. F in C Major.

Koch, in his Lexicon (art. Verbindungs Accord), has placed his accidental harmonies in a different point of view. He considers them as connecting chords, and seems to agree with Kirnberger, who asserts that, by a species of transition, the harmony of the triad is thus united to another of its inversions.

III. Of the added ninth. When to the chord of the dominant seventh the ninth is also joined, a chord of five sounds is formed. It rises from the root by regular thirds, in the following manner:



In C Major.



In A Minor.

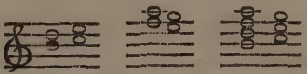
This harmony being generally used in four parts, the radical base is commonly omitted; for the leading note is always sufficiently powerful to guide the ear to its proper root. In this form the two chords have been already described.

The added ninth of the dominant is really the submediant of the scale, or sixth from the tonic; it is consequently major in the major mode, and minor in the minor mode. Thus, although there is but one added seventh, there are two added ninths.

The omission of the root forms a chord of the seventh on the leading note, which may be known from the other sevenths (either of the sequence or of suspension) by its resolution into the tonic. It may sometimes be prepared, but is generally used without preparation.

None of the inversions of this seventh are employed in the major scale, but all are used in that of the minor.

This chord has been considered as a combination of the dominant and subdominant harmonies, since it contains the B and D of the former, and the A and F of the latter, while the resolution of D and F falls on the same note.



Dominant. Subdominant. Union of both.

It is observable, that the above combination of sounds includes every note of the scale, excepting the three notes of the triad on the tonic, and that it also decides the mode of the scale, since the sixth or submediant is part of the chord of the subdominant, which is major or minor, according to the key.

The same chord in the minor mode consists of three minor thirds; and its extreme notes are the sharp seventh and minor sixth of the scale. It is of such great importance in modern music, that it is termed the diminished seventh, or equivocal chord. In the resolution of its parts, it conforms to that of the major chord in the last example.

The radical base of this chord may be found in extreme modulations by two methods.

I. By the major third below the last sharp.

II. By the semitone below the last flat.

When naturals occur, the observations concerning them must be strictly regarded.

This chord is not only considered as a direct harmony, but all its three inversions are occasionally employed.

In those keys where the clef does not agree with the modulation, the second inversion requires a flat or natural under the sharp fourth.

These two chords of the added ninth have been termed chords of major and of minor substitution; since they are considered as derived from the dominant seventh, by substituting the ninth in the place of the eighth.

They are also styled chords of borrowed harmony; since the seventh and ninth are supposed to be derived or borrowed from the subdominant.

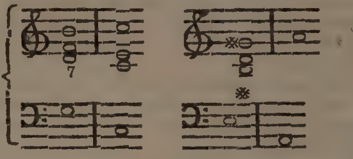
All these chords are liable to have any of their sounds suspended on the following tonic harmony; and hence arise many figured bases, too numerous to be inserted within the limits of the present work.

Chap. IV.—Of Cadences.

A cadence in harmony consists of two distinct chords (the last of which is generally accented), and is used to terminate the sections and periods of musical rhythm.

When the bases of both chords are the roots of their respective triads, the cadence is termed radical; and, of these radical cadences, there are four in general use, the perfect, imperfect, false, and mixt: to these may be added the plagal or church cadence, which is only a variation of the imperfect; and the authentic, which is only the ancient term for the perfect.

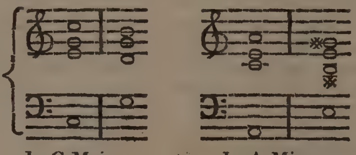
I. The perfect cadence consists of the dominant harmony, followed by that of the tonic; thus,



In C Major. In A Minor.

The first or leading harmony is always major.

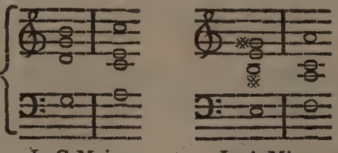
II. The imperfect cadence consists of the tonic, followed by the dominant without its added seventh, and is the former cadence reversed.



In C Major. In A Minor.

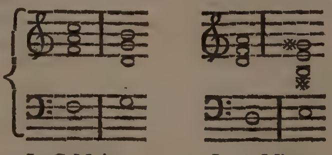
The second or final harmony is always major.

III. The false cadence consists of the dominant, followed by the submediant (in diatonic gradation) taken in the place of the tonic. In the major mode this cadence forms the interval of a tone; in the minor mode, only a semitone; and it is used instead of the perfect cadence, from which it is derived.



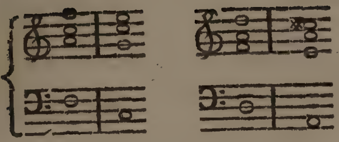
In C Major. In A Minor.

IV. The mixt cadence is the direct gradation of the subdominant to the dominant, and is used instead of the imperfect cadence, from which it is derived.



In C Major. In A Minor.

The plagal cadence only differs from the imperfect as to its place in the scale, being the progression of the subdominant to the tonic. This is used as a final cadence in church music, particularly in the Hallelujah Chorus, Messiah, and in the Coronation Anthem, Zadoc the Priest.



In C Major. In A Minor.

The final chord of this is always major.

The authentic cadence is the same as the perfect, and is only so termed in contradistinction to the plagal.

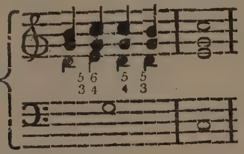
When the leading harmony of any cadence is not radical, but inverted, the cadence is, in this work, termed medial, and is used to express an incomplete close.

I. Cadence of the leading note.—This is the first inversion of the dominant, and is used instead of the perfect cadence.

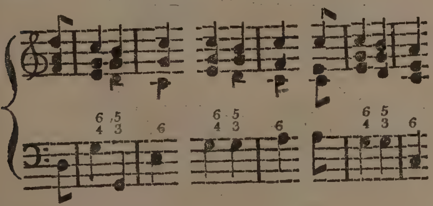
II. Cadence of the sharp sixth.—This is the second inversion of the dominant, and is sometimes used as a final cadence on the tonic, as in *Non Nobis Domine;* but more generally on the sixth of the descending scale, when it commonly bears a suspended seventh.

III. Cadence of the major or minor sixth.—This is the first inversion of the mixt cadence, and is chiefly used in the minor mode. It is also liable to the antecedent suspension of the seventh.

These cadences may also become protracted by using other harmonies on the dominant. Thus is formed what Dr. Pepusch calls the grand cadence.



To these may be added those deceptive cadences, which, by varying the final chord, avoid the final close.



Chap. V.—Of Sequences.

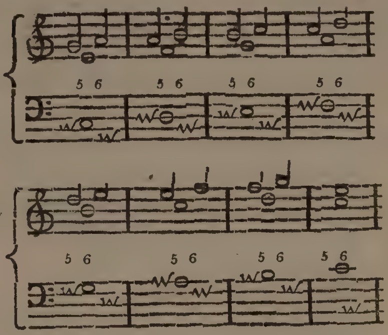
Any similar succession of chords in the same scale, ascending or descending diatonically, is, in this work, termed a sequence.

All sequences are particularly distinguished by the irregularity of making the leading note a temporary root, to avoid modulation out of the original scale.

I. *Of dominant sequences.*—The principal descending sequence is that of sevenths; an example of which has been already given, derived from the progression of rising fourths and falling fifths in the dominant motion.

II. *Of mediant sequences.*—The principal ascending sequence is that known by a 5 followed by a 6, on a gradual progression of the diatonic scale. It is derived from the mediant progression.

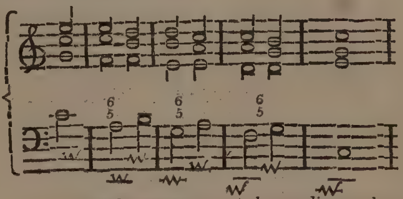
In this, and the following examples, the directs shew the radical base.



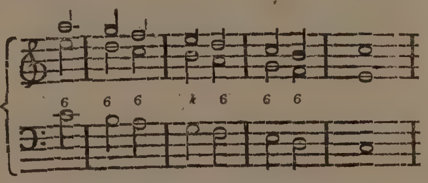
This sequence, like that of sevenths, admits of the leading note as a temporary root; and it seems to have been for the sake of elucidating these passages, that Kirnberger and Kollmann have admitted the diminished triad among the consonant harmonies.

III. *Of inverted sequences.*—The principal inverted sequences are those derived from the sequence of sevenths; and, of these, the most usual is that of a 7, followed by a 6 on the gradual descending progression of the scale.

It is not unusual, in the first inversion of the sequence of sevenths (that of the fifth and sixth), to leave every other harmony as a simple triad, in the following manner:

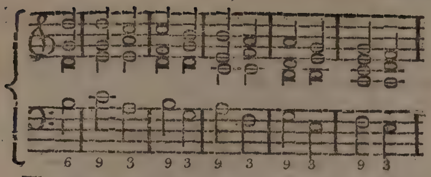


IV. *Of simple sequences.*—A descending scale may also be accompanied by a simple sequence of sixths alone. The theory of this progression is involved in some difficulty; but the uniform practice of authors, both ancient and modern, has established its use.



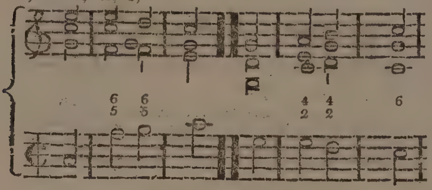
The same series may take place ascending; and the effect is nearly that of the medial sequence of 5 and 6

V. *Of compound sequences.*—Compound sequences are those which by employing the chords of suspension, change their harmonies on the alternate base. Of these there are various kinds; one of the principal is that of descending thirds with alternate ninths; thus,

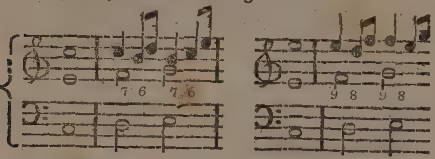


These sequences also may be doubly compounded, and then bear double suspensions.

To these may be added the partial sequences of two similar harmonies, frequently found in Handel, &c.; thus,



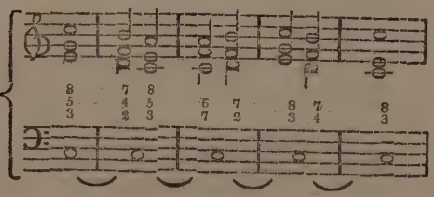
VI. *Of irregular sequences.*—It is not unusual to find an ascending scale accompanied with 7 and 6, with 9 and 8, or with their compounds $\begin{smallmatrix}9\\7\end{smallmatrix}$ and $\begin{smallmatrix}8\\6\end{smallmatrix}$, which form *irregular* sequences. These chords belong regularly to a descending series.



In these sequences the unaccented harmony must be divided in half, after the resolution of the discord, to prepare the following one, as in the antecedent example; the 7th is then prepared by the 8th, and the 9th by the 10th. There are many other kinds of sequences, but the preceding examples will suffice in this place.

Chap. VI.—Of Licences.

Of pedal harmonies.—When the dominant harmony is taken unprepared upon the tonic base as a holding note, whether preceded by the tonic or by the subdominant harmony, the passage is termed a tonic pedal note or organ point.



In the chord of $\begin{smallmatrix}7\\4\\2\end{smallmatrix}$ the dominant note itself is generally omitted, for reasons before given; and the chord appears (independent of the holding base) like that of the sharp sixth on the supertonic.

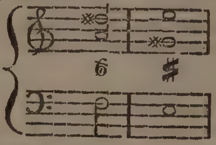
Also when any chords, or sequences, are taken upon the dominant base, as a holding note, a similar passage is formed; and the base then also becomes a dominant pedal note or organ point.

Not only the simple dominant, but its compound derivative, the added ninth, may be taken on a tonic pedal. Hence arises the chord of the sixth and seventh, or the thirteenth of Marpurg. This is used in the minor mode on the tonic, and sometimes, by extreme licence, on the dominant.

Not only these, but any other chords, whether of suspension, sequence, &c. &c. may be taken on the tonic, or the dominant, as a pedal base; and some instances occur, in which these sounds may be retained in a superior part.

Of the extreme sharp sixth.—When, upon the first inversion of the mixt cadence, the sixth of the submediant (or fourth of the scale) is accidentally sharpened, the chord of the extreme sharp sixth is formed.

This harmony, when accompanied simply by the third, has been termed the Italian sixth.

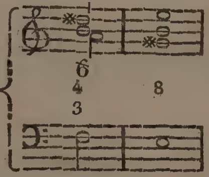


Root B.

By this alteration of the fourth, the species of cadence is changed, from the first inversion of the mixt to the second inversion of the perfect; and it is considered as a licence, because the root bears a flat fifth, while at the same time the third continues major.

The radical base, therefore, of the extreme sharp sixth, is the supertonic of the key; and its fifth is allowed to be defective, that the original minor mode may not be totally destroyed.

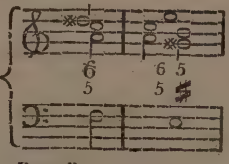
When to the simple combination of the Italian sixth the root itself is annexed, a chord of third, fourth, and sixth is formed; and, as this harmony is only found in the theory of Rameau, it may be properly termed the French sixth.



Root B.

A harmony still more remote, but extremely powerful, is formed upon this chord, by inserting the added ninth on the root, as a supposed dominant to the real one.

This occurs with great effect in the writings of Graun, &c. and therefore may be called the German sixth.

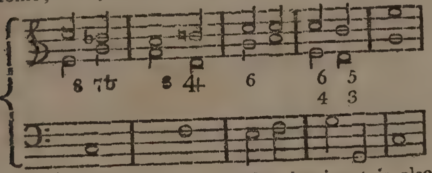


Root B.

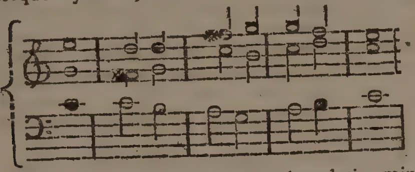
It requires, however, a continuation of its third and fifth on the dominant base (as a new fourth and sixth), to prevent the consecutive fifths.

Of partial modulation.—Whenever the dominant and tonic of a new key are employed without the subdominant harmony, such change constitutes a partial modulation.

One change of this kind arises when the seventh of the major mode is flattened, and the modulation returns again through the leading note to the tonic; thus,



Another change towards the dominant is also frequently used; thus,

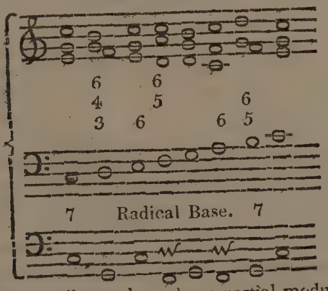


Many other changes occur, to the relative minor (or submediant), to the mediant, to the supertonic, &c. some of which are peculiar to the music of the last forty years.

Of the rule of the octave.—It may at first sight appear singular to class this celebrated progression among musical licences; but, as the descending scale equally includes a partial modulation, and rejects the original subdominant harmony, so essential to the constituent parts of the key, the propriety of the classification must appear obvious.

When a diatonic scale in the base is accompanied with harmony according to this rule, the roots and their inversions are thus intermixed:

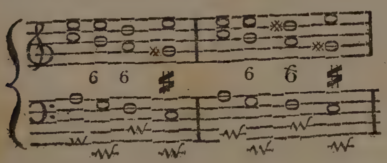
Ascending Scale.



The descending scale makes a partial modulation into the dominant.

In the minor mode, the inversion of the mixt cadence takes place, which, in modern music, is generally varied by the Italian sixth.

The Directs mark the Roots of the Chords.

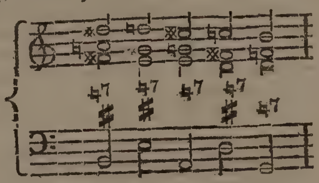


The remainder of the scale coincides with that of the major mode.

Although this scale is given in the above form by most of the theoretical writers, yet, in practical music, such is the prevalence of partial modulations, varied sequences, &c. that the rule is not often found complete.

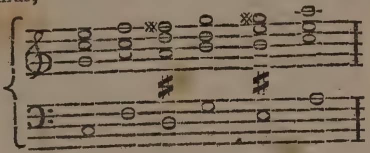
Of chromatic modulation.—When the chromatic semitones are introduced between the notes of the diatonic scale, chromatic modulation is formed, in which the key is continually, although partially, changing.

As the diatonic sequence of sevenths is used to avoid modulation, so a chromatic sequence of sevenths consists of dominants alone, and the scale changes at every chord; thus,



This sequence forms a descending chromatic scale.

In a similar manner may be formed an ascending chromatic sequence, derived from that of 5 and 6; thus,

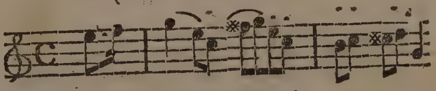


This also makes a partial change at every other harmony.

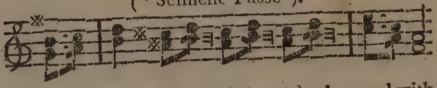
In modern music, a species of chromatic transition is employed, in which the semitones occur, not as parts of the radical harmony, but as appoggiaturas, after-notes, or acciaccaturas.

The two following examples, from the celebrated opera of Mozart, the Zauberflöte, are instances of chromatic appoggiaturas.

("Wie stark its nicht").

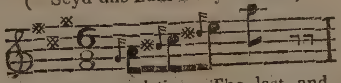


("Schnelle Fusse").



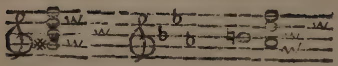
The acciaccatura, or half beat, is also used with great effect in a terzett, from the same piece.

("Seyd uns zum zweytenmal").



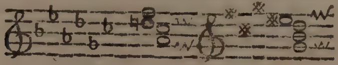
Of enharmonic modulation.—The last and most difficult branch of harmony is that which arises from the sudden change of key made by the enharmonic diesis.

When any one of the sounds of the equivocal chord is called by a new name, and placed on a new degree, the root, scale, and signature, all change at once.



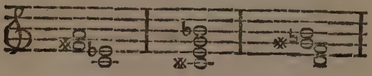
Root E, Key A Minor. Root G, Key C Minor.

As this harmony consists of four sounds, each of which may be altered by the diesis, the two following modulations arise from the same chord.



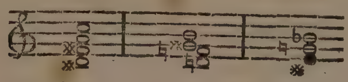
Root B flat, Key E flat Minor. Root C sharp, Key F sharp Minor.

As the chromatic octave upon keyed instruments consists of twelve different sounds (exclusive of the diatonic eighth or replicate of the first), there are but three different chords, in respect of the keys themselves, on the key-board. These, in their simplest forms, are the added ninths of D, A, and E, dominants of their respective minors.



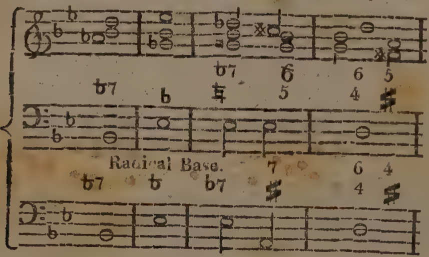
Each of these chords, by the use of the diesis, may change into three other harmonies; and thus an immediate step to any one of the twelve minor modes may be gained.

These chords may also, under certain limitations, succeed each other chromatically, descending or ascending.



Root B Root E Root A
(Descending.)

The last and most unusual species of enharmonic modulation, is that which changes the dominant seventh into the German sixth. A remarkable instance occurs in Handel's Solomon, at the chorus, "Draw the tear from hopeless love;" thus,



to express the words, "full of death and wild despair."

For the fourth general topic usually considered in treatises of music, that is rhythm, see the article Rhythm in this work. See also part ii. of Dr. Calcott's valuable Musical Grammar, which may likewise be advantageously consulted, for many other examples in illustration of the precepts and observations here given. Those who wish to study the mathematical and philosophical theory of musical sounds are referred to Gregory's Translation of Hauy's Natural Philosophy, vol. i. p. 311—340. See also the articles Æolus's Harp, Base *thorough*, Chords, Generator, Harmony, Key, &c. in their proper places in this dictionary.

The plates numbered 116, 117, 118, and 119, exhibit interesting specimens of English, Scotch, and German music. For many highly admirable specimens of Welsh and Irish music we must refer the curious reader to the collections of Welsh and Irish melodies recently published.

MU'SICAL. *a.* (*musical*, French, from *music*.) 1. Harmonious; melodious; sweet sounding (*Milton*). 2. Belonging to music (*Addison*).

MU'SICALLY. *ad.* (from *musical*.) Harmoniously; with sweet sound (*Addison*).

MU'SICALNESS. *s.* (from *musical*.) Harmony.

MUSI'CIAN. *s.* (*musicien*, French.) One skilled in harmony; one who performs upon instruments of music (*Bacon*).

MUSK. An odoriferous substance of a peculiar nature, secreted into a bag, situated near the umbilical region of the moschus moschifer of Linnéus, a ruminating animal, resembling the antelope. (See Moschus.) This bag, according to Newmann, has no external opening, like that of the civet cat, whence musk is not to be gotten till after the death of the animal.

In the article alluded to above, we have observed that in commerce two sorts of musk are distinguished, the Tonquin or Indian, and the Muscovy or Persian. Musk is either of a dark brown or rusty reddish colour: sometimes clothed like coagulated blood. To the touch it is unctuous, and on drying becomes pulverizable. It has a bitterish savour, and its aroma is peculiarly strong and aromatic, disagreeable if too concentrated, but when largely diluted with other matters, or greatly extended in the atmosphere, it becomes a pleasant perfume. From its aroma being remarkably diffusive and tenacious, every thing in its vicinity becomes thoroughly infected with it, and retains it a long time. Water extracts two-fifths of it by distillation; and is greatly with its aroma and savour: alkohol takes up one-third of it, but retains little or nothing of its aroma. Nitric and sulphuric acids totally dissolve it, the first destroying the whole, the second the greater part of its aroma.

Soda extracts from it the smell of ammonia, when these two substances are rubbed together. Oils have no action upon it. Cast on red-hot coals, it emits the same fetid smell as urine. On distillation, Newmann obtained the same products as from other animal substances, viz. an empyreumatic oil, a volatile spirit and salt.

By impregnating the waters and spirits distilled from odoriferous vegetables with a minute portion of musk, their fragrance is considerably improved, without receiving any of its own peculiar aroma.

Musk cavy. Musk-rat. See Mus.

Musk cranesbill. See Geranium moschatum.

Musk ox. See Bos.

MU'SKET. *s.* (*musquet*, French.) 1. A soldier's hand-gun (*Bacon*). 2. A male hawk of a small kind (*Shakspeare*).

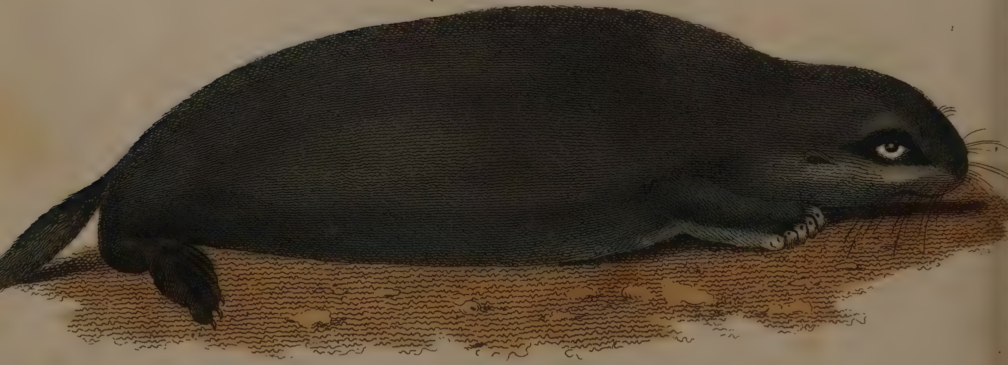
M. Erminea; Ermine.



M. Lutra or Sea Otter.

London, Published by Sherwood & Co. Paternoster Row, April 1st 1812.

MUSKETE'ER. *s.* (from *musket.*) A soldier whose weapon is his musket (*Clarend.*)

MUSKETO'ON. *s.* (*musqueton*, French.) A blunderbuss; a short gun of a large bore.

MU'SKINESS. *s.* (from *musk.*) The scent of musk.

MUSLIN, a fine thin sort of cotton-cloth, which bears a downy knap on its surface. There are several sorts of muslins brought from the East Indies, and more particularly from Bengal; such as doreas, betelles, mulmuls, tanjeebs, &c.

MUSQUITO, in entomology. See CULEX.

MU'SROL. *s.* (*muserole*, French.) The noseband of a horse's bridle (*Bailey*).

MUSS. *s.* A scramble (*Shakspeare*).

MUSSÆNDA, in botany, a genus of the class pentandria, order monogynia. Corol funnel-form; stigmas two, thickish; berry oblong, inferior; seeds disposed in four rows. Three species, natives of India or China, climbing or upright shrubs.

MUSSINIA, in botany, a genus of the class syngenesia, order polygamia frustranea. Receptacle villous; down simple; floret of the ray ligulate; calyx one-leafed, cylindrical; toothed. Six species, all Cape plants.

MUSSELBURG, a seaport in Edinburghshire, on the frith of Forth, at the mouth of the river Esk. Here a victory was obtained by the English over the Scots in the reign of Edward VI. It is six miles E. of Edinburgh. Lon 35 W. Lat. 56. 0 N.

MUSSITA'TION. *s.* (*mussito*, Lat.) Murmur; grumble.

MUSSULMAN, or MUSYLMAN, a title by which the Mahometans distinguish themselves; signifying, in the Turkish language, true believer, or orthodox. (See MAHOMETANISM) In Arabic the word is written Moslem, Mosleman, or Mosolman. The appellation was first given to the Saracens, as is observed by Leunclavius.

MUSWELL HILL, a village in Middlesex, five miles N. of London. It takes its name from a famous well on the hill, which belonged to the fraternity of St. John of Jerusalem, in Clerkenwell; and as this was deemed a miraculous cure for all scrophulous and cutaneous disorders, they here built a chapel, with an image of our Lady of Muswell, to which there was a great resort of patients. This well still belongs to the parish of Clerkenwell.

MUST. *verb imperfect.* (*mussen*, Dutch.) To be obliged; to be by necessity. It is only used before a verb. *Must* is of all persons and tenses, and used of persons and things.

MUST. *s.* (*mustum*, Latin.) New wine; new wort (*Dryden*).

To MUST. *v. a.* (*mws*, Welsh, stinking.) To mould: to make mouldy (*Mortimer*).

To MUST *v. n.* To grow mouldy.

MUSTA'CHES. *s.* (*mustaches*, French.) Whiskers; hair on the upper lip (*Spenser*).

MUSTARD, in botany. See SINAPIS.

MUSTELA. Otter. Ferret. Stoat. In zoology, a genus of the class mammalia, order feræ. Fore-teeth, upper six, erect, acuter, distinct; lower six obtuser, crowded, two placed within; tongue smooth. Twenty-eight species, scattered over the globe, six of them common to our own country. In many respects the otter-tribe of this genus very nearly resembles the weesel tribe; the body in both being long, of the same thickness, feet short, hair shining, claws immoveable; both burrow in the ground, and prowl and prey by night: but the otters live mostly in the water, swim on the surface, and under, feed chiefly on fishes, do not climb, or leap with the body curved and tail stretched out like the weesels; head larger and thicker, tongue strewed with soft prickles: otters have five grinders in each jaw, on each side; weesels have four, five, or six. The genus may be subdivided as follows.

A. Hind-feet palmate. Otters.

B. Feet cleft. Weesels.

The following species are the chief.

1. M. lutra. Common or greater otter. Short ears, eyes placed near the nose, thick lips, and large whiskers. Colour of the whole body deep brown, except two small spots on each side of the nose, and another beneath the chin: the throat and breast ash-coloured: legs short and thick, loosely joined to the body; capable of being brought on a line with the body, and of performing the part of fins: each toe connected to the other by a broad strong web.

Its usual length is twenty-three inches; its tail measures sixteen: the weight of the male from eighteen to twenty-six pounds; of the female, from thirteen to twenty-two.

It inhabits all parts of Europe, the north and north-east of Asia, as far as Kamschatka, and in the easternmost of the Fox islands: but abounds in North America, particularly in Canada, where the most valuable furs of this kind are produced. It dwells on the banks of rivers, and burrows, forming the entrance of its hole beneath the water, whence it works upward, making a small orifice or air-hole in the midst of some bush. It is a cleanly animal, and deposits its excrements only in one place: swims and dives with great ease: is very destructive to fishes; but when these fail, makes excursions on land, and preys on lambs and poultry: is said to hunt its prey against the stream, that it may return with greater ease with its booty. It frequents not only fresh waters, but also sometimes ventures out to sea, though it never goes far from the shore in quest of prey. It frequently gives a sort of loud whistle, by way of signal to another. It is a fierce animal, and its bite dangerous; yet it is capable of being tamed, and made to follow its master like a dog, and even to fish for him, and to return with its prey. These animals sometimes breed in sinks and drains. They dread neither cold nor moisture. The female comes in season in winter, and brings forth in the month of March four or five young ones at a time. Contrary to what happens to most other animals, the young otter is not so handsome as the old.

Mr. Pennant conjectures that the latax of Aristotle was a large variety of this species.

2. M. lutreola. Lesser otter. Resembling the preceding, but only one-third of its size. Feet very hairy, toes equal, mouth white; tail dusky, broad, darker towards the end. Inhabits marshy places in Germany, Poland, Finland, Russia, and Siberia: feeds on fishes and frogs; fetid; fur valuable: caught with dogs and in traps.

3. M. minx. Minx. Body entirely deep chesnut. Inhabits North America, on the banks of rivers; feeds on fishes, birds, mice; sometimes haunts farm-yards.

4. M. lutris. Sea otter. Hind-feet hairy; tail a fourth part as long as the body. Another variety black, with a yellow spot under the throat. Nose black; upper jaw larger and broader than the under; whiskers white; irids hazel; ears small, erect, conic; skin thick; hair thick and long, excessively black and glossy; beneath a soft down: colour sometimes varies to silvery: legs thick and short: toes covered with hair, and joined by a web: hind feet exactly like those of a seal, and have a membrane skirting the outside of the exterior toe, like that of a goose. Length of the body about three feet; of the tail, thirteen inches and a half: tail flat, fullest of hair in the middle, and sharp-pointed. The biggest of these animals weigh seventy or eighty pounds. They are found in great abundance in Bering's island, and the Fox islands; they are harmless and inoffensive creatures, most affectionate to their young: they will pine to death for the loss of them, and die on the very spot where they have been taken from them. Before the young can swim, they carry them in their paws, lying in the water on their backs. They are swift in running, and very sportive: embrace, and even kiss each other. They swim often on their backs, on their sides, and even in a perpendicular posture. They inhabit such shallows as abound with sea-weeds, and feed on lobsters, fishes, sepiæ, and shell-fishes. They breed only once a year, bring but one at a time, and suckle it for a year: are dull sighted, but of a very quick scent. They are hunted for their skins, which are of great value; and are sold to the Chinese for seventy or a hundred rubles a piece. Each skin weighs three pounds and a half. The young are reckoned such delicate meat, that their flesh is scarcely to be distinguished from that of a sucking lamb.

5 M. vulgaris. Common weesel. Body tawny-brown, beneath white; tail colour of the body. Another variety with the body white; tip of the tail with a few black hairs. Found in our own country; and inhabits the temperate and cold regions of Europe, Asia, and America: in Russia, becomes white in winter; half the size of the ermine; eats fishes, flesh, mice, eggs, and mushrooms, but no other vegetables; preys by night; gets into the holes of mice and devours them, leaving the teeth only; fetid; dirty; drinks often; cunning; continually looks about; is not easily destroyed by a cat; when terrified becomes epileptic; playful when tamed; brings from six to eight young.

6. M. Canadensis. Pekan. Body blackish, tawny; on the breast a white spot. Inhabits Canada; about two feet long; tail ten inches.

7. M. foina. Martlett. Martin. Body blackish; tawny; throat and breast white; belly deep-brown; feet hairy; claws white; length eighteen inches; tail ten. Inhabits most parts of southern Europe, and is a native of England; preys by night on poultry, eggs, frogs, birds, and ripe fruit; an enemy to cats; easily tamed when young; female brings from three to seven young, and breeds in hollow trees.

8. M. zebellina. Sable. Body dark-tawny; forehead white; throat cinereous.

B. Another variety snowy white.

C. A third variety with a collar of white round the neck. Resembes the martin; head longer; ears longer; yellow at the margin: mouth whiskered. Inhabits the northern parts of Asia and America, Siberia, Kamschatka, the Kurile islands: sleeps by day; preys by night on smaller weesels, squirrels, and hares; in winter on birds, particularly partridges; in autumn on berries: attacks cats; gravid three mouths; brings from three to five young; fur very precious.

In the more barbarous times of the Russian empire the hunting of these animals was the employment, or rather the task, of those unhappy exiles that were sent into Siberia. As that country is now become more populous, the sables have, in a great measure, quitted it, and retired further north and east, to live in desert forests and mountains. They usually reside on the banks of rivers, or on the little islands in them.

At present the sable hunters form themselves into parties or troops, from five to forty each: the last subdivide into lesser parties, and each chooses a leader; but there is one commander in chief that directs the whole. A small covered boat is prepared for each party, laden with provision, a dog and a net for every two men, and a vessel to bake their bread in. Each party has also an interpreter for the country they intend to penetrate. Every party then sets out, according to the course their leader points out. They ascend the rivers, drawing up their boats, till they arrive in the hunting country. There they stop, build huts, and wait till the waters are frozen, and the season commences. Before they begin the chase, their leader assembles them; they join in a prayer to the Almighty for success, and then separate. The first sable each party takes is called God's sable, and is dedicated to the church.

They then penetrate into the woods, and mark the trees as they advance, that they may know their way back. In their hunting-quarters they form huts of trees, and bank up the snow around them. Near these they lay their traps; then advance farther, and lay more traps; still building new huts in every quarter, and returning successfully to every old one, to visit the traps, and to take out the game, and to skin it, which none but the chief of the party must do. During this time they are supplied with provisions by persons who are employed to bring it on sledges from the places on their route, where they are obliged to form magazines. The traps are a sort of pit-falls, with a loose board placed over each, baited with fish or flesh. When sables grow scarce, the hunters trace them on the new fallen snow to their holes, place their nets at the entrance, and sometimes wait, watching, two or three days, for the coming out of the animal. It has happened that these poor people have, by the failure of their provisions, been so pinched with hunger, that, to prevent the cravings of appetite, they have been reduced to take two thin boards, one of which they apply to the pit of the stomach, the other to the back, drawing them tight together by cords placed at the ends. Such, says Mr. Pennant, are the hardships our fellow-creatures undergo, to supply the wantonness of luxury!

The season of chase being finished, the hunters re-assemble, report to their leader the number of sables each has taken, make complaints of offenders against their regulations, punish delinquents, and share the booty. They then continue at the head-quarters till the rivers are clear of ice; when they return home, and give to every church the dedicated furs.

The price of these furs varies from one to ten pounds sterling, and above. Fine and middling skins are sold without the bellies; the coarse ones with them. The finest sables are sold in pairs perfectly similar; and such pairs are dearer than single ones of the same goodness; for the Russians want those in pairs for facing caps, cloaks, and tippets. The blackest are reputed the best. Sables are in season from November to February: those caught at any other time of the year are short-haired. The hair of sables differs in length and quality: the long hairs, which reach far beyond the inferior ones, are called os. The more a skin has of such long hairs, and the blacker they are, the more valuable is the fur. The very best have no other but those long black hairs. Below the long hairs there are, in the greater part of sable furs, some shorter, called podosie or under os. The more podosie a fur has, the less valuable it is. Between the os and podosie there is a low woolly kind of hair called podsada. The more podsada a fur has, the less valuable it is reputed; for the long hair will, in that case, take no other direction than the natural one: but the character of sables is, that notwithstanding the hair lies from the head towards the tail, yet it will lie in any direction you strike your hand over it. Beside various other particulars respecting the fur, the furriers attend much to the size, always preferring, *cæteris paribus*, the biggest, and those that have the greatest gloss. The gloss vanishes in old furs: the fresh ones have what dealers in furs call a bloomy appearance; the old ones are said to have done blooming. The dyed sables always lose their gloss, and become less uniform, whether the lower hairs have taken the dye or not; and the hairs are commonly twisted or crisped, and not so straight as the natural ones. Some fumigate the skins, to make them look blacker; but the smell, and the crisped condition of the long hair, betrays the cheat: but dying and fumigating are both detected by rubbing the fur with a moist linen cloth, which grows black in such cases. The Chinese, however, have a way of dying the sables, so that the colour not only lasts, which is more than the Russian cheats can effect; but the fur keeps its gloss, so that the fraud can only be detected by the crisped hairs.

The country about the river Ud affords sometimes sables, of which one is often sold for twelve or fourteen pounds sterling. The bellies of sables, which are sold in pairs, are about two fingers breadth, and are, like the skins, tied together in parcels of forty each. One of these parcels sells from one to two pounds sterling: tails are sold by the hundred; the very best furs must have their tails, but ordinary ones are often cropped. A hundred sells for from four to eight pounds. White sables are rare: they are not common merchandize, but bought only as curiosities. Some are yellowish, and are bleached in the spring on the snow. The common sables are scarcely any thing better in hair and colour than the martin.

The sable is also found in North America. The Russians have often discovered the skins mixed with those of martins in the fur dresses, which they get from the Americans by way of exchange. Their fur is more glossy than that of the Siberian sable, and of a bright chesnut colour, but of a coarser quality.

The length of the American sable is about twenty inches; the trunk of the tail is only five; but from the rump to the end of the hairs eight. His ears are more pointed than those of the Asiatic sable: its feet are large and hairy, both above and below: it has five toes, with white claws on each foot. The colour of its head and ears is whitish: its whiskers are short and black; its whole body of a light tawny; its feet are brown.

This species and one or two of the ensuing are erroneously referred by some naturalists to the genus VIVERRA, which see.

9. M. putorius. Pole-cat. Body blackish-yellow; mouth and ears white. Differs from the martin in having the head thicker; tail shorter; in the deserts of Russia sometimes found white; male yellowish, with a whitish mouth; female paler. Inhabits most parts of Europe and Asiatic Russia: dwells in stony places; frequents stables, granaries, houses, hollow trees, and shallow burrows; sleeps by day, wanders by night in search of rabbits, mice, moles, poultry and small birds, in the winter frogs and fishes; steals eggs; robs bee-hives; emits from the arms when agitated a most fetid vapour.

10. M. furo. Ferret. Eyes red, fiery: less than the polecat; head narrower; snout sharper; body longer, slenderer; colour pale-yellow. Inhabits Africa; tamed in Europe to catch rabbits; procreates twice a year; gravid six weeks; brings from six to eight, rarely nine, young; very fetid.

11. M. erminea. Tail black at the tip. Two varieties.

α. Body with a red tinge. Stoat.
β. Body white; tail blackish at the tip. Ermine.

The body of this species is ten inches long; the hair short, not so shining as in the martin; in northern climates becomes white, except the outer half of the tail, which remains black. Inhabits Europe, the cold parts of America, Asia, China; lives in heaps of stones, banks of rivers, hollow trees, and forests, especially of beech; preys on squirrels, mice, and small animals: the fur of the ermine is very valuable. See ERMINE; as also Nat. Hist. Pl. CLIX.

To MU'STER. *v. n.* To assemble in order to form an army (*Blackmore*).

To MU'STER. *v. a.* (*mousteren*, Dutch.) To bring together; to form into an army (*Locke*).

MU'STER. *s.* (from the verb.) 1. A review of a body of forces (*Ben Jonson*). 2. A register of forces mustered (*South*). 3. A collection: as, *a* muster *of peacocks*. 4. *To pass* muster. To be allowed.

MU'STERBOOK. *s.* (*muster* and *book.*) A book in which the forces are registered (*Shakspeare*).

MU'STERMASTER. *s.* One who superintends the muster to prevent frauds (*Knolles*).

MUSTER-ROLL, a specific list of the officers and men in every regiment, troop, or company, which is delivered to the inspecting field officer, muster-master, regimental or district paymaster (as the case may be), whereby they are paid, and their condition is known. The names of the officers are inscribed according to rank, those of the men in alphabetical succession. Adjutants of regiments make out the muster-rolls, and when the list is called over, every individual must answer to his name. Every muster-roll must be signed by the colonel or commanding officer, the paymaster and adjutant of each regiment, troop, or company; it must likewise be sworn to by the muster-master or paymaster (as the case may be), before a justice of the peace, previous to its being transmitted to government.

MU′STILY. *ad.* (from *musty.*) Mouldily.

MU′STINESS. *s.* (from *musty.*) Mould; damp foulness (*Evelyn*).

MU′STY. *a.* (from *must.*) 1. Mouldy; spoiled with damp; moist and fetid (*Bacon*). 2. Stale; spoiled with age (*Shakspeare*). 3. Vapid with fetidness (*Pope*). 4. Dull; heavy; wanting activity; wanting practice in the occurrences of life (*Addison*).

MUTABI′LITY. *s.* (*mutabilité*, French.) 1. Changeableness; not continuance in the same state (*Stillingfleet*). 2. Inconstancy; change of mind (*Shakspeare*).

MU′TABLE. *a.* (*mutabilis*, Latin.) 1. Subject to change; alterable (*South*). 2. Inconstant; unsettled (*Milton*).

MU′TABLENESS. *s.* (from *mutable.*) Changeableness; uncertainty; instability.

MUTA′TION. *s.* (*mutation*, French; *mutatio*, Latin.) Change; alteration (*Bacon*).

MUTE. *a.* (*muet*, Fr. *mutus*, Lat.) Silent; not vocal; not having the use of voice (*Dryden*).

Mute. In case any person refuses to plead to an indictment for felony, &c. he is now by stat. 12 Geo. III. c. 20, to be considered as pleading guilty, and to be punished as upon confession. Formerly a plea was extorted from him by a process, which was called the *peine forte et dure*, and which has been justly considered as inhuman and disgusting.

Mute is also a sporting term, applied to a hound when he pursues his game by the scent, without giving tongue. As some are by much too free, and give tongue too hastily, when in a state of uncertainty, acquiring thereby the denomination of babblers, so there are others equally tardy in proclaiming the discovery. Hounds of each description are considered jurious to the discipline and desirable excellence of the pack, and are generally rejected as soon as their imperfections are known, and confirmed.

Mute, in a general sense, signifies a person that cannot speak, or has not the use of speech.

Mute, in grammar, a letter which yields no sound without the addition of a vowel. The simple consonants are ordinarily distinguished into mutes and liquids, or semi vowels. (See the articles Consonant, Liquid, &c.) The mutes in the Greek alphabet are nine, three of which, viz. π, κ, τ, are termed *tenues:* three, β, γ, δ, termed *mediæ*; and three, φ, χ, θ, termed *aspirates*. (See the article Aspirate, &c.) The mutes of the Latin alphabet are also nine, viz. B, C, D, G, I, K, P, Q, T.

To Mute. *v. n.* (*mutir*, French.) To dung as birds (*Tobit*).

MU′TELY. *ad.* (from *mute.*) Silently; not vocally (*Milton*).

MUTIC. In botany, awnless. Opposed to aristate, awned, in Philos. Botan. Mutica gluma; acumine destituta Without any point at the end. Delin. Pl. In this sense we have arista mutica: which can mean only blunt, or having no acumen or sharp point. This term is applied to the calyx in serratula; and to the anthers in erica herbacea.

MUTILATE. Mutilus flos. In botany, a mutilated flower. Not producing a corol, when it ought regularly to do it. This defect is commonly owing to a want of sufficient heat, either from climate or situation; sometimes it is the effect of culture.

To Mu′tilate. *v. a.* (*mutiler*, Fr.) To deprive of some essential part (*Addison*).

MUTILA′TION. *s.* (*mutilation*, Fr.) Deprivation of a limb, or any essential part (*Clarendon*).

MUTILLA, a genus of insects, of the order hymenoptera: the generic character is, antennas filiform; feelers four; the articulations obconic, seated on the tip of the lip; jaw membranaceous at the tip, lip projecting obconic; wings in most species obconic; body pubescent, thorax retuse behind; sting pungent, concealed. The M. helvola inhabits the Cape of Good Hope. There are thirty-eight species.

MUTINA, the ancient name of Modena.

MU′TINE. *s.* (*mutin*, Fr.) A mutineer (*Shakspeare*).

MUTINEE′R. *s.* (from *mutin*, French.) A mover of sedition; an opposer of lawful authority (*Dryden*).

MU′TINOUS. *a.* (*mutine*, French.) Seditious; busy in insurrection; turbulent (*Wal.*).

MU′TINOUSLY. *ad.* (from *mutinous.*) Seditiously; turbulently (*Sidney*).

MU′TINOUSNESS. *s.* (from *mutinous.*) Seditiousness; turbulence.

To MU′TINY. *v. n.* (*mutiner*, Fr.) To rise against authority; to make insurrection; to move sedition (*South*).

Mu′tiny. *s.* (from the verb.) Insurrection; sedition (*Temple*).

Any officer or soldier who shall presume to use traiterous or disrespectful words against the sacred person of his majesty, or any of the royal family, is guilty of mutiny.

Any officer or soldier who shall behave himself with contempt or disrespect towards the general or other commander in chief of our forces, or shall speak words tending to their hurt or dishonour, is guilty of mutiny.

Any officer or soldier who shall begin, excite, cause, or join in, any mutiny or sedition, in the troop or company, or regiment, to which he belongs, or in any other troop or company in our service, or on any party, post, detachment, or guard, on any pretence whatsoever, is guilty of mutiny.

Any officer or soldier who, being present at any mutiny or sedition, does not use his utmost endeavours to suppress the same, or coming to the knowledge of any mutiny, or intended mutiny, does not without delay give information to his commanding officer, is guilty of mutiny.

Any officer or soldier who shall strike his superior officer, or draw, or offer to draw, or shall lift up any weapon, or offer any violence against him, being in the execution of his office, on any pretence whatsoever, or shall disobey any lawful command of his superior officer, is guilty of mutiny.

MUTISIA, in botany, a genus of the class syngenesia, order polygamia superflua. Receptacle naked; down feathery; calyx cylindrical, imbricate; florets of the disk three-cleft. Eleven species, natives of Chili and Peru; most of them climbing plants, some with pinnate, others with simple leaves.

MUTITAS. (*mutitas*, from *mutus*, dumb.) Dumbness. A genus of disease in the class locales and order dyscinesiæ of Cullen: containing three species, viz. 1. Mutitas organica, as happens when the tongue is removed or injured. 2. Mutitas atonica, arising from an affection of the nerves of the organ. 3. Mutitas surdorum, depending upon being born deaf.

MUTIUS (Cælius), first named Codrus, and afterwards Scævola, an illustrious Roman, who distinguished himself greatly in the war with Porsenna. When that prince besieged Rome, Mutius entered his camp in order to assassinate him, but, by mistake, stabbed one of his attendants. On being seized and brought before Porsenna, he said that he was one of 300 youths who had engaged, by oath, to take away his life. He added, "This hand, which has missed its purpose, ought to suffer." Then, without hesitation, he thrust it into some coals which were burning on the altar, and suffered it to be consumed. Porsenna, struck with this intrepidity, made peace with the Romans. The name of Scævola, which means left-handed, was afterwards annexed to all of this family.

MUTSCHEN, a town of Upper Saxony, in the circle of Leipsic. In the neighbourhood is found a species of crystal, to which is given the name of Mutschen diamond. It is 20 miles E. of Leipsic. Lon. 12. 50 E. Lat. 51. 14 N.

To MU'TTER. *v. n.* (*mutire*, Latin.) To grumble; to murmur (*Dryden*).

To MU'TTER. *v. a.* To utter with imperfect articulation; to grumble forth (*Creech*).

MU'TTER. *s.* (from the verb.) Murmur; obscure utterance (*Milton*).

MU'TTERER. *s.* (from *mutter.*) Grumbler; murmurer.

MU'TTERINGLY. *ad.* (from *muttering.*) With a low voice.

MU'TTON. *s.* (*mouton*, French.) 1. The flesh of sheep dressed for food (*Swift*). 2. A sheep: in ludicrous language (*Hayward*).

MUTTONFI'ST. *s.* (*mutton* and *fist.*) A hand large and red (*Dryden*).

MU'TUAL. *a.* (*mutuel*, French.) Reciprocal; each acting in return or correspondence to the other (*Pope*).

MU'TUALLY. *ad.* (from *mutual.*) Reciprocally; in return (*Newton*).

MUTUA'LITY. *s.* (from *mutual.*) Reciprocation (*Shakspeare*).

MUTULE, in architecture, a kind of square modillion, set under the corniche of the Doric order. The only difference between the mutule and modillion consists in this, that the former is used in speaking of the Doric order, and the latter in the Corinthian.

MU'ZZLE. *s.* (*museau*, French.) 1. The mouth of any thing (*Sidney*). 2. A fastening for the mouth, which hinders to bite (*Dry.*).

To MUZZLE. *v. n.* To bring the mouth near (*L'Estrange*).

To MUZZLE. *v. a.* 1. To bind the mouth (*Dryden*). 2. To fondle with the mouth close (*L'Estr.*). 3. To restrain from hurt (*Shakspeare*).

MY. *pronoun possessive.* Belonging to me.

MYA. Gaper. In zoology, a genus of the class vermes, order testacea. Animal an ascidia: shell bivalve, generally gaping at one end: hinge with broad, thick, strong teeth, seldom more than one, and not inserted into the opposite valve. Twenty-six species, scattered through the seas and rivers of the globe. Six common to our own coasts. The animals of this genus perforate into the sand and clay at the bottom of the sea, or beds of rivers, burying themselves or their shells wholly or in part. The following are the chief:—

1. M. declivis. Shell brittle, semitransparent, sloping downwards near the open end: the hinge slightly prominent. Found about the Hebrides: the fish in great esteem as a food among the inhabitants.

2. M. pictorum. Painter's mya. Shell ovate; with a single, longitudinal, crenulate tooth in one hinge, and two in the other. There are six or seven varieties of this species: some of them are found in the fresh waters of Britain and other parts of Europe, some in Barbary, some in Tranquebar. The shell is commonly used to put water colours in, whence its specific name. One inch and three quarters long, three and a half broad; covered with a brownish or blackish coat, and under this yellowish or greenish, with green rays; within smooth and clay-colour; very thin and brittle, and does not gape at either end.

3. M. margaritifera. Pearl mya. Shell ovate, a little contracted in the middle of the thinner margin; primary tooth of the hinge conic; protuberant parts over the hinge decorticated. Inhabits most of the arctic circle, and is generally found in mountainous rivers and about cateracts; about five inches broad and two and half long: shell thick, coarse, opake, transversely wrinkled, black on the outside, and often corroded by worms; hinge without lateral teeth, the primary tooth being received into a broad cleft tooth of the opposite hinge. This shell is celebrated for producing large quantities of mother of pearl and pearl, these latter being a disease of the fish analogous to the stone in the human body. The river Con-

way in Wales was formerly famous for producing pearls of great size and value.

From observations on the growth of these shells and the number of their annual laminæ or scales, it has been supposed that this fish will attain a great age, and that fifty or sixty years is a very moderate computation. Linnéus, however, appears to have made a remarkable discovery upon this subject; to have shewn that the fish will bear removing well, and that by a particular process it may be put into a state of producing pearls at our pleasure in the reservoirs to which it is transferred, the old pearls being removed to make way for the formation of new ones: we are not, however, in possession of the process which he pursued to accomplish this desideratum.

MYACANTHA. In botany. (*myacantha*, μυακανθα; from μυς, a mouse, and ακανθα, a thorn, so called because its prickly leaves are used to cover whatever is intended to be preserved from mice.) Butcher's broom. See Ruscus.

MYAGRUM. Gold of pleasure. In botany, a genus of the class tetradynamia, order siliculosa. Silicle inversely heart-shaped, with concave valves, and terminated by a conic style; the cell mostly one-seeded. Ten species, chiefly natives of the warmer regions of Europe. Of these, M. perenne is the most common, a native of Germany, with two-jointed, one-seeded silicles; leaves outwardly sinuate, denticulate: stem branched, diffuse, rough; flowers yellow.

MYCALE, a city and mountain of Caria; also a promontory of Asia opposite Samos, celebrated for a battle which was fought there between the Greeks and Persians about the year of Rome 275. The Persians were about 100,000 men, who had just returned from the unsuccessful expedition of Xerxes in Greece. They had drawn their ships to the shore, and fortified themselves strongly, as if determined to support a siege. They suffered the Greeks to disembark from their fleet without the least molestation, and were soon obliged to give way before the cool and resolute intrepidity of an inferior number of men. The Greeks obtained a complete victory, slaughtered some thousands of the enemy, burned their camp, and sailed back to Samos with an immense booty, in which were 70 chests of money.

MYCETOPHAGUS, in zoology, a tribe of coleopterous insects of the Fabrician system, belonging to the genus Silpha, which see.

MYCONE, an island of the Archipelago, 30 miles in circumference. The harbour is very open, and deep enough for the largest ships, where they may ride secure from the N. wind. The soil is dry, and the mountains are of a great height. Water is very scarce in summer; but in the town is a large well, the only one in the island. Here are plenty of partridges, quails, woodcocks, turtledoves, rabbits, and wheatears; also excellent grapes and figs. Almost all the inhabitants are Greeks, who have 50 churches in all; but many are chapels, and some monasteries. Lon. 25. 51 E. Lat. 37. 28 N.

MYCTERIA. Jabiru. In zoology, a genus of the class aves, order grallæ. Bill a little bending upwards, sharp-pointed, upper mandible triangular; front bald; nostrils linear; tongue small or tongueless; feet four-toed, cleft. Three species, as follow:

1. M. Americana. White; quill and tail-feathers purplish black. In multiplying the reptile tribes, which swarm upon those watery tracks that border upon the Amazons and Oroonoko, nature, at the same time, has not only multiplied those birds which are their destroyers, but also proportioned their size and strength to those of the enormous serpents they are to devour.

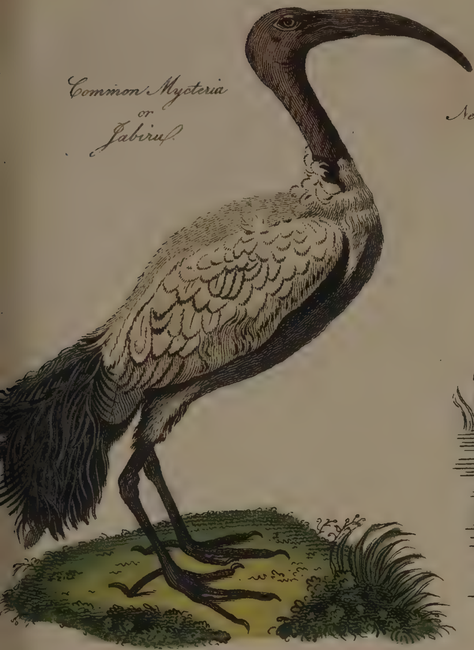
The American jabiru, one of the largest birds in Guiana, is evidently destined for this purpose: it is more than four feet high; it is six in length, from the tip of the beak to that of the claws; and is entitled to the first rank in the order of waders. The large black bill of this bird is a formidable weapon, being above thirteen inches long, and, at the base, three in thickness. It is upon a large head; is supported by strong muscles inserted into its base; and consists of a horny substance, bent upwards at the top. The head, and two-thirds of the neck of the jabiru, are covered with a black and naked skin, thinly interspersed with a few grey hairs. The plumage on the lower part of the neck is red, and gives the bird the appearance of wearing a large collar, while it affords a fine contrast with the rest of the plumage, which is pure white. These birds grow fat in the rainy season, and are then killed by the natives, who reckon them good eating. The species is gregarious and migratory; it feeds on fishes chiefly, which it devours in large quantities; builds in trees hanging over the water, and lays two eggs.

2. M. Asiatica. Indian jabiru. White: band over the eyes; lower part of the back, quill and tail feathers black. Inhabits India; feeds on shell-fishes.

3. M. Novæ Hollandiæ. New Holland jabiru. Body, above purplish-green, beneath, neck and shoulders white; head purplish, spotted with white; irids yellow; first quill-feathers white; tail black and white. Inhabits New Holland. See Nat. Hist. Pl. CLXI.

MYDAS, in the entomological system of Fabricius, a tribe of the genus Musca, which see.

MYDRIASIS. (*mydriasis*, μυδριασις; from μυδαω, to abound in moisture; so named because it was thought to originate in redundant moisture). A disease of the iris. Too great a dilation of the pupil of the eye, with or without a defect of vision. It is known by the pupil always appearing of the same latitude or size in the light. The species of mydriasis are, 1. Mydriasis amaurotica, which for the most part, but not always, accompanies an amaurosis. 2. Mydriasis hydrocephalica, which owes its origin to an hydrocephalus internus,



Common Mycteria
or
Jabiru.

or internal dropsy of the ventricles of the cerebrum. It is not uncommon amongst children, and is the most certain diagnostic of the disease. 3. Mydriasis verminosa, or a dilatation of the pupil from saburra and worms in the stomach or small intestines. 4. Mydriasis a synechia, or a dilatation of the pupil, with a concretion of the uvea with the capsula of the crystalline lens. 5. Mydriasis paralytica, or a dilated pupil, from a paralysis of the orbicular fibres of the iris; it is observed in paralytic disorders, and from the application of narcotics to the eye. 6. Mydriasis spasmodica, or from a spasm of the rectilineal fibres of the iris, as often happens in hysteric and spasmodic diseases. 7. Mydriasis atonica, from atony of the iris, the most frequent cause of which is a large cataract distending the pupil in its passing when extracted. It vanishes in a few days after the operation, in general; a pupil, however long dilated, may remain so from the over and long-continued distension.

MYGINDA, in botany, a genus of the class tetrandria, order tetragynia. Calyx four-parted; petals four; drupe globular. Three species, natives of the West Indies or South America: the most elegant of which is M. aragoga, a South American shrub, with leaves somewhat heart-shaped, pointed, slightly serrate, pubescent, opposite and sessile; corymb axillary; dark, shining red flowers; and soft red fruit.

MYIAGRUS DEUS, in the heathen mythology, a name given sometimes to Jupiter and sometimes to Hercules; when sacrifices are offered to either for the purpose of driving away flies.

MYLABRIS, in the entomological system of Fabricius, a tribe of the genus Meloe, which see.

MYLO. In myology. Names compounded with this word belong to muscles which are attached near the grinders; from μυλη, a grinder tooth; such as,

Mylo-hyoideus. This muscle, which was first described by Fallopius, is so called from its origin near the dentes molares, and its insertion into the os hyoides. It is a thin flat muscle, situated between the lower jaw and the os hyoides, and is covered by the anterior portion of the digastricus. It arises fleshy, and a little tedinous, from all the inner surface of the lower jaw, as far back as the insertion of the pterygoideus internus, or, in other words, from between the last dens molaris and the middle of the chin, where it joins its fellow, to form one belly, with an intermediate tendinous streak, or linea alba, which extends from the chin to the os hyoides, where both muscles are inserted into the lower edge of the basis of that bone. This has induced Riolanus, Winslow, Albinus, and others, to consider it as a single penniform muscle. Its use is to pull the os hyoides upwards, forwards, and to either side.

Mylo-pharyngeus.(*musculus mylo-pharyngeus*, μυλοφαρυγγαιος; from μυλν, the grinding tooth, and φαρυγξ, the pharynx). A muscle arising near the molares, and inserted in the pharynx. See Constrictor pharyngeus superior.

MYODESOPSIA. (*myodesopsia*, μυωδεσωψια; from μυαι, a fly, and ωψια, vision). A disease of the eyes, in which the person sees black spots, an appearance of flies, cobwebs, or black wool, before his eyes.

MYO'GRAPHY, a description of the muscles.

MYOLOGY. (*myologia*, μυολογια; from μυς, a muscle, and λογος, a discourse.) The doctrine of the muscles. See Anatomy.

MYOMANCY, a kind of divination, or method of foretelling future events by means of mice. Some authors hold myomancy to be one of the most ancient kinds of divination; and think it is on this account that Isaiah, lxvi. 17. reckons mice among the abominable things of the idolators. But, beside that it is not certain that the Hebrew word עכבר used by the prophet signifies a mouse, it is evident it is not the divination by that animal, be it what it will, that is spoken of, but the eating of it.

MYONIMA, in botany, a genus of the class tetrandria, order monogynia. Calyx very minute, nearly entire; corol four-parted, with a short tube; drupe with a four-celled, four-seeded nut. Two species, natives of the isle of Bourbon, with opposite leaves and terminal flowers.

MYOPA, in the entomological system of Fabricus, a tribe of the genus Conops, which see.

MYOPIA. (*myopia*, μυωπια: from μυω, to wink, and ωψ, the eye). Near-sighted, purblind. The myopes are considered those persons who cannot see distinctly above twenty inches. The myopia is likewise adjudged to all those who cannot see at three, six, or nine inches. The proximate cause is the adunation of the rays of light in a focus before the retina. The species are, 1. Myopia, from too great a convexity of the cornea. The cause of this convexity is either from nativity, or a greater secretion of the aqueous humor: hence on one day there shall be a greater myopia than on another. An incipient hydrophthalmia is the origin of the myopia. 2. Myopia, from too great a longitude of the bulb. This length of the bulb is native, or acquired from a congestion of the humours in the eye; hence artificers occupied in minute objects, as the engravers of seals, and persons reading much, frequently after puberty become myopes. 3. Myopia, from too great a convexity of the anterior superficies in the crystalline lens. This is likewise from birth. The parallel rays which fall into the cornea, by so much they fall more obliquely, so much the more convex is the cornea, or crystalline lens, or vitreous humour in the anterior superficies. But the angle of refraction is equal to the angle of incidence: therefore the angle of refraction so much sooner will be formed as the cornea or lens is more convex. This perfectly accounts for short-sightedness; but an anterior too great convexity of the cornea is the most common cause. 4. Myopia, from too great a density of the cornea, or humours of the eye. Optics teach us, by so much sooner the rays of light are forced into a focus, by so much the diaphanous body is denser. 5. Myopia, from a mydriasis or too dilated a pupil; for so much the wider the aperture of the diaphragma is in an optical instrument, so much the nearer is the focus. 6. Myopia infantilis. Infants, from the great convexity of the cornea, are often myopes; but by degrees, as they advance in years, they perceive objects more remotely, by the cornea becoming less convex.

MYOPORUM, in botany, a genus of the class didynamia, order angiospermia. Calyx five-parted; corol campanulate, with a spreading, nearly equal, five-parted border; drupe one or two-seeded, with two-celled nuts. Four species, natives of New Zealand or New Caledonia, very nearly related to the genus citharexylon.

MYOPS. (*myops, opis*, μυωψ, from μυω, to wink, and ψω, the eye). One who is near-sighted.

MYOSIS. (*myosis*, μυωσις). A contraction or too small perforation of the pupil; it is known by viewing the diameter of the pupil, which is smaller than usual, and remains so in an obscure place, where, naturally, if not diseased, it dilates. It occasions weak sight, or a vision that remains only a certain number of hours in the day; but if wholly closed, total blindness. The species of this disorder are, 1. Myosis spasmodica, which is observed in the hysteric, hypochondriac, and in other spasmodic or nervous affections; it arises from a spasm of the orbicular fibres of the iris. 2. Myosis paralytica arises in paralytic disorders. 3. Myosis inflammatoria, which arises from an inflammation of the iris or uvea, as in the internal ophthalmia, hypopium, or wounded eye. 4. Myosis, from an accustomed contraction of the pupil. This frequently is experienced by those who contemplate very minute objects; by persons who write; by the workers of fine needle-work; and by frequent attention to microscopical enquiries. 5. Myosis, from a defect of the aqueous humour, as after extraction. 6. Myosis nativa, with which infants are born. 7. Myosis naturalis, is a coarctation of the pupil by light, or from an intense examination of minutest objects. These coarctations of the pupil are temporary, and spontaneously vanish.

MYOSITIS. (*myositis*, μυοςιτις, from μυς, a muscle). Inflammation of a muscle. It is the term given by Sagar to acute rheumatism.

MYOSOTIS. (*myosotis*, μυοςωτος, from μυς, a muscle, and ȣς, ωτος, an ear; so called because its leaves are hairy, and grow longitudinally like the ear of a mouse). In botany, a genus of the class pentandria, order monogynia. Corol salver-shaped, five cleft, slightly notched; the throat closed with concave valves. Eleven species, scattered over the globe; of which the most remarkable is M. scorpioides, common mouse-ear, or, as it is sometimes called, scorpion-grass; a plant indigenous to the walls and sands of our own country, with smooth seeds; lance-elliptic leaves; racemes many-flowered without bractes; more or less hairy, varying in the colour of its flowers.

MYOSURUS. Mouse-tail. In botany, a genus of the class pentandria, order polygynia. Calyx five-leaved, each with a spur at the base; petals five, with a tubular, nectariferous claw; seeds numerous, naked. One species only; a weed found in the corn-fields of our own country, with fibrous root, radical linear-spatulate, rather obtuse leaves, and small, erect, yellowish-green flowers.

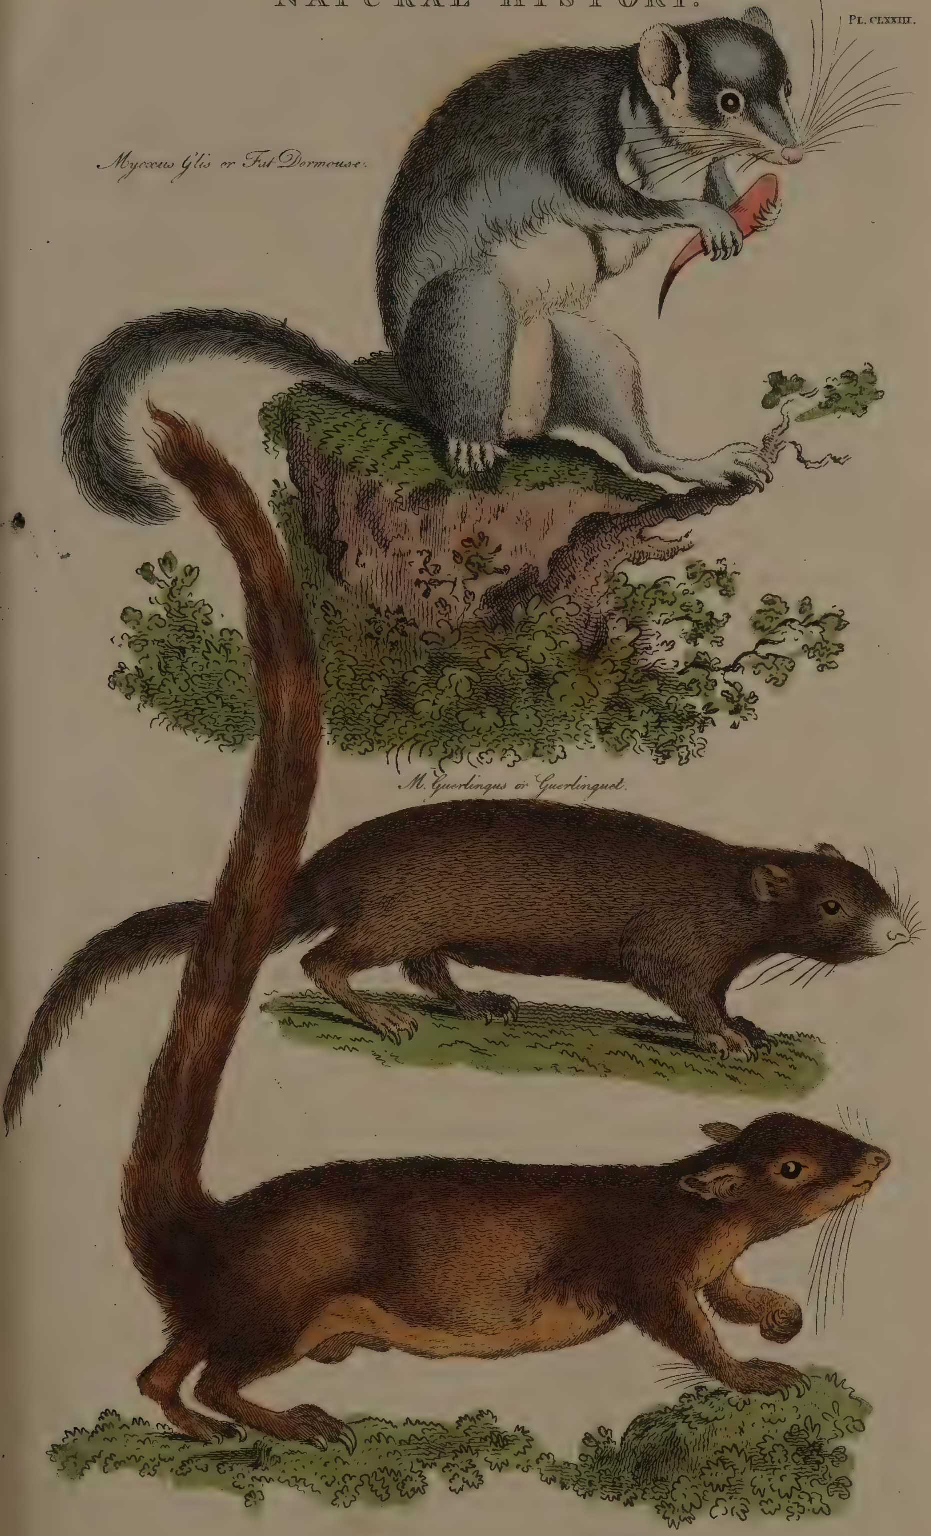
MYOXUS. Dormouse. In zoology, a genus of the class mammalia, order glires. Fore-teeth two, upper wedged, lower compressed sideways; whiskers long; tail hairy, round, thicker towards the tip; feet nearly equal in length, four toes before. These animals remain torpid during the winter; walk or rather leap on their hind legs, bounding three or four feet at a time, in which they are assisted by their long stiff tail; feed only on vegetables; burrow under ground; sleep by day, watch by night; carry food to the mouth by the fore-paws, and drink by dipping the fore-palms in water. Four species, as follow:

1. M. glis. Fat dormouse. The glis of Pliny, and the old naturalists: mus glis of Pallas. Sciurus glis of the Systema Naturæ. Le loir of Buffon. Body hoary; beneath whitish; ears thin, naked; cheeks white; whiskers longer than the head; teats ten, six pectoral, four abdominal. Inhabits the woods of Europe and southern Asia; feeds on nuts, walnuts, apple-seeds: forms its nest in hollow trees: bites; sleeps by day; grows very fat in autumn; about October retires by troops into subterraneous caverns, and remains torpid till the end of May; brings from nine to twelve young; six inches long, the tail five. The flesh was formerly esteemed a great delicacy by the Romans, who fattened them as food in receptacles, named gliraria. Its general manners resemble those of the squirrel; it is not easily tamed.

2. M. dryas. Wood dormouse. Body above tawny-grey, beneath dirty-white; a straight black line from ear to ear across the eyes. Inhabits Europe; differs from the rest only in colour; tail shorter, more bushy; no black spots near the ears.

3. M. nitela. Garden dormouse. Body above tawny, beneath whitish ash; a black circle round the eyes, and a black spot behind the ears, which are oblong; eyes large, black. Inhabits Siberia, and the southern parts of Europe, chiefly in gardens, where it destroys all kinds of fruits, especially peaches; makes its nest in holes of walls and hollow trees; smells like a rat; brings from five to six young; body five inches long, tail four.

4. M. muscardinus. Common dormouse. Body tawny; throat whitish; hind-thumbs without claws; eyes large, black, prominent; ears short, round, naked, thin; tail bushy at the tip; body plumper than that of the mouse.



Myoxus Glis or Fat Dormouse.

M. Guerlingus or Guerlinguet.

London, Published by Sherwood & C^o. Paternoster Row, May, 1^st 1812.

inhabits Great Britain and other parts of Europe in woods, and thick hedges, seldom in gardens; collects nuts and walnuts, which it eats sitting upright, and buries what is left; forms a nest of grass, moss, or leaves, in the hollow of a tree or low bush; torpid in winter; brings from three to four young: body three inches long, tail rather longer.

MYOTOMY. (*myotomia*, μυοτομία, from μυων, a muscle, and τεμνω, to cut.) Dissection of the muscles.

MY'RIAD. *s.* (μύριας.) 1. The number of ten thousand. 2. Proverbially any great number (*Milton*).

MYRICA. Candleberry myrtle. In botany, a genus of the class monoecia, order tetrandria. Calyx, a concave scale of the ament; corolless. Female: styles two; berry one-seeded. Nine species scattered over the globe; of which the following are chiefly cultivated:

1. M. gale. Sweet gale, sweet willow, common candleberry myrtle, Dutch myrtle. It is found wild in our own marshes; rises with many shrubby stalks from two to near four feet high, dividing into several slender branches, covered with a dusty bark, sprinkled with white dots; leaves alternate, rigid, light or yellowish green, smooth, a little serrate towards their point, and emitting a fragrant odour when bruised; aments of a short ovate figure, yellowish-brown colour, and frequently sprinked with shining, resinous, golden particles; fruit a coriaceous berry. It is said that in the north of Europe this plant was used instead of hops in former times, and that it is still applied to the same use in the Hebrides, and some parts of the highlands of Scotland.

2. M. cerifera, American candleberry myrtle. Leaves lanceolate, slightly serrate, stem arboreous, rising to about thirty feet in height; flowers in aments on different individuals; male aments about an inch long, erect; female, sessile, axillary, shorter than the leaves: the branches of the old plants shed their leaves in autumn; but the young plants raised from seeds retain them through the greatest part of the winter, and offer the appearance of an evergreen. The flowers are small, of a whitish colour, and mean to the eye. Its leaves resemble myrtle leaves, and like them, on being rubbed in the hand, emit a most refreshing and delightful fragrance.

It is from the berries of this plant that the inhabitants of Carolina and other parts of America collect a wax, of which they very generally make candles. The wax is produced as follows. In November or December the wild berries are gathered by persons who are used to this occupation, and travel for this purpose with kettles towards the sand-banks or sea-side, in which these plants most abound; they build huts for themselves and their families with palmetto leaves, and usually continue about five weeks in a station. The trees are cut down, the berries put into porridge-pots, and afterwards boiled in water till the oil floats; this is then skimmed off into another vessel, and the skimming is continued as long as any oil rises to the surface. When cold it hardens to the consistency of wax, and is of a dirty green colour. It is then boiled again, and clarified in brass kettles, which gives it a transparent green hue. The candles manufactured from this wax burn for a long time, and produce a fragrant smell: a small proportion of tallow however is usually added, which makes them burn clearer.

3. M. quercifolia. Oak-leaved candleberry myrtle. Shrubby, with slender stalks, and oblong, oppositely pinnate leaves, with oval aments between them. The plant retains its leaves all the year, and flowers in June and July.

The two first species may be raised from seeds, the last by layers. The former require a boggy moist situation, or a cultivation in bog-earth. The layers of M. quercifolia should be attempted towards the latter end of the summer, or in the autumn, the shoots being twined at a joint when laid down, and well watered.

The first two are introduced into the midst of sheltered clumps and borders, and the last into collections of the green-house kind, when their leaves afford an exquisite fragrance.

MYRIOPHYLLUM. Water millfoil. In botany, a genus of the class monoecia, order hexandria. Calyx four-leaved; petals four. Male: stamens eight, longer than the calyx. Female: stigmas four; seeds four, covered with a bark. Two species, both common to the ditches of our own country.

MYRISTICA. Nutmeg-tree. In botany, a genus of the class dioecia, order triandria. Calyx three-cleft, corolless. Male: anthers uniting round the upper part of the filament. Female: stigma cloven, capsule superior, drupaceous, two-valved; nut invested with a variously lacerated membrane. Three species:

1. M. sebifera. A Guiana tree, with leaves hearted, oblong, downy underneath, and downy fruit. The tree rises from forty to sixty feet high, discharging a thick acrid red juice from its trunk on its being wounded; and yields a nutmeg, from which a considerable portion of fatty oil is expressed, employed by the natives of Guiana in the manufacture of candles.

2. M. fatua. A nutmeg-tree of Tobago, rising to the height of our common apple-tree; with oblong, lanceolate, downy leaves, and downy fruit. The nutmeg is aromatic, but narcotic; and when taken in considerable quantity produces delirium.

3. M. aromatica. Calyx ovate, three-cleft at the top: leaves elliptic, pubescent underneath, alternate, pointed, undulate; peduncles axillary, solitary, two or three-flowered; fruit glabrous; nut surrounded with a fulvous, tough, reticulate covering, which is the mace of the shops.

It is doubtful whether the Greeks or Romans were acquainted with the nutmeg. It is said by some that Theophrastus alludes to it under the name of comacum, and by others that it is the chrysobalanos of Galen. Yet we know nothing decisively upon the subject. It was first introduced into modern Europe by the Arabians, and in Avicenna it appears under the name of jiansiban, or jansiband, which signifies nut of Banda.

Both the male and female flowers yield a nut. The female nut is that in common use; the male is longer and more cylindric, but it has less of fine aromatic flavour. It is more subject to be worm-eaten, and to harbour the insect that preys upon the nutmeg, than the female; and hence the Dutch strictly prohibit its being packed up with the latter, lest the worm should be communicated to the whole package. The chief nutmeg trade lies at Ceylon; and has passed, with the islands, from the hands of the Dutch to those of the English.

When the fruit is ripe the natives ascend the trees, and gather it by pulling the branches towards them with long hooks. The first rind is instantly taken off, and the soil on which any large quantity of this is deposited shoots forth very speedily a nutmeg-boletus, or mushroom, from the putrefaction of the general mass, which is regarded by the natives as a very delicate food.

The mace is a filamentous substance, adhering to the nut, and traced after the external rind has been removed. Its first appearance presents a beautiful red; but the colour changes on exposure to the air to a darker hue. The mace being taken off with the knife, is laid to dry in the sun for eight or nine hours, and is then removed to a place less heating, that it may not become too dry; to prevent which, in a still greater degree, it is moistened with a small quantity of sea-water; and is afterwards put into small bags, and packed up very close.

The mace being thus stripped off, the nuts are still covered with their ligneous shell; and are exposed for three days to the sun, and afterwards to the fire, till they emit a sound on being shaken: they are then beaten with small sticks, which break the remaining shells, and make them fly off in small pieces. The nuts are then distributed into three parts: the largest and most beautiful are selected for the European market; those of less beauty are reserved for the use of the inhabitants, or are employed for the purpose of affording oil by pressure: while the remainder, which consists of the smallest and the unripe, are burnt. A pound of nutmegs generally affords about three ounces of oil, of the consistence of tallow, and has all the taste of the nutmeg. This is the genuine oil of mace of the shops.

To preserve the select nutmegs, and fit them for an European voyage, they are plunged in small baskets, two or three times, into a thick lime-water prepared with the calcined shells of testaceous fishes, to which a considerable quantity of sea-salt has been added. With this calcareous matter they soon become completely covered over; when they are laid in a heap, and lose their superfluous water by evaporation. They are then properly prepared for sea-carriage.

For the medical properties and preparations of nutmeg, see the article NUX MOSCHATA, under which name it has been generally prescribed in the different pharmacopœias.

MYRMECIA, in botany, a genus of the class tetrandria, order monogynia. Calyx campanulate, five-toothed; corol tubular, with an inflated throat; glands five, surrounding the base of the germ; capsule two-celled, two-valved, many-seeded. One species: a climbing shrub of Guiana, with knotty square branches; leaves opposite, oblong; flowers small, solitary, axillary.

MYRMECOPHAGA. Ant-eater. In zoology, a genus of the class mammalia, order bruta. Toothless; tongue round, extensile; mouth narrowed into a snout; body covered with hair. Seven species, inhabitants of South America, Cape of Good Hope, Australasia, or India. The following are the chief.

1. M. jubata. Great ant-eater. Toes on the fore-feet four, on the hind-feet five; tail bushy.

Another variety, with face and legs shorter, without a stripe on the sides and breast. The former and more common variety has a long slender nose; small black eyes; short round ears; slender tongue, two feet long, which lies double in its mouth; slender legs; the two middle claws on the fore-feet very large, strong, and hooked. The hair on the upper part of the body half a foot long, black mixed with grey. Across its shoulders there is a black stripe bounded above with white. The forelegs whitish, with a black spot above the feet. The hair of the tail coarse, black, and about a foot long. This animal is about three feet ten inches long; its tail two: it weighs above a hundred pounds. Inhabits Brazil and Guiana; runs slowly; swims over the great rivers, at which time it flings its tail over its back: lives on ants; overturns their nests, or digs them up with its feet, then thrusts its long tongue into their retreats, and withdraws it into its mouth loaded with prey: is afraid of rain, and protects itself from it by covering its body with its long tail: it does not attainits full growth under four years. Each species of this genus brings but one young one at a time. Notwithstanding its want of teeth, it is fierce and dangerous, especially when it has young. Nothing that it has once got between its fore-feet can disengage itself; the very panthers of America are often unequal to the combat. So great is its obstinacy and stupidity, that it will not extricate itself even from a dead adversary. It sleeps in the day, and preys by night. Its flesh has a strong disagreeable taste; but it is eaten by the Indians.

2. M. didactyla. Least ant-eater. Toes on the fore-feet two, on the hind-feet four: tail bushy: nose conic, bending a little down; small ears, hid in its fur; upper parts covered with long soft silky hair, or rather wool, of a yellowish brown colour: seven inches and a half long: its tail, which is thick at the base, and tapers to a point, measures eight and a half, and is naked on the under side for the last four: it inhabits Guiana, and climbs trees in

quest of a species of ants which build their nests among the branches. It has the size and prehensile power of the squirrel: walks slowly on the heels; feeds only in the night; emits no cry.

3. M. pentadactyla. Striped ant-eater. Toes on the fore-feet five: tail long, flat, entirely covered with hair: head thick, upper jaw and snout very long, eyes small; ears small, rounded, fringed above with black hairs; hair long; back, head, legs tawny; belly dirty white; tail annulate with blackish hair: length thirteen inches, height ten.

4. M. aculeata. Porcupine ant-eater. Body covered with long sharp spines: tail very long. Spines on the back and sides resembling those of a porcupine, white, with black tips, and a circle of dull orange between the colours; head and under-parts deep-brown; tail short, naked, a little flattened at the tip, covered at the root with upright spines; eyes small, black, irids blueish; legs short, thick, five-toed; toes broad, round; claws black, on the hind-feet only four, the first long, sharp, carved, second shorter, two others shorter still. Inhabits New Holland: size of a rat.

5. M. Capensis. Cape ant-eater. Toes on the fore-feet, four; snout long; ears large, pendulous; tail shorter than the body, tapering to the tip. Inhabits the Cape of Good Hope; nearly the size of a hog, and weighing almost a hundred pounds; burrows in the ground; sleeps by day, prowls by night. See Nat. Hist. Pl. CLV.

MYRMELEON. Lion-ant. Mouth with a horny acute mandible and jaw; feelers six; stemmaless; antennas thicker at the tip; wings deflected; tail of the male armed with a forceps composed of two straight filaments.

The animals of this family prey with the most savage ferocity upon ants and smaller insects, though they seem at first sight but ill calculated for this manner of life, all their progress in walking being backwards: by stratagem, however, the lion-ant masters insects far superior to itself in strength. In the loose sand it digs a hollow resembling a funnel, where it takes its station at the bottom, every part being concealed except the forceps, with which the head is armed. This instrument, which it can open or shut at pleasure, is curiously constructed for seizing and penetrating the hardest insect; and unhappy is the animal who, in pursuing it journey, stumbles into this cavern. In vain it endeavours to scramble up by the edges, which are continually giving way under its feet; it tumbles to the bottom, where it is pierced by the forceps of the lion ant lurking below.

If the insect be small, and the grains of sand, notwithstanding the declivity of the funnel, do not give way under its feet, the myrmeleon has another invention by which he renders himself master of his prey; with his head, which is flattened, he throws up repeated showers of sand from the bottom of the funnel, which falling upon the sides, force down the insect till it comes within reach. The fatal instruments with which this animal seizes its prey are each a sort of mouth or trunk, by which it sucks out the entire entrails.

When the lion-ant has attained its full size, it constructs for itself an edifice, the external parts of which are particles of sand or earth combined together by silken threads: the interior cavity is lined with pure silk, white and glossy, like satin. Within this ball the myrmeleon is changed into a chrysalis, of a curved or semicircular shape, displaying all the parts of the perfect insect that is soon to issue from it.

After the chrysalis bursts, the winged insect which makes its escape is of a gray colour, with a long slender body, resembling the libellula. In this country the myrmeleon is very scarce; a few, however, are found to breed among the loose earth at the bottom of walls which have a south exposure. In that dry, pulverized, and sandy earth their eggs are protected from rain, till they are hatched by the sun. Vallisnieri and Poupart first gave the history of the lion-ant; that of the former is in the form of a dialogue between Malphighi and Pliny, in which the modern informs the ancient naturalist of the singular manœuvres and metamophosis of these animals. There are sixteen species; which may be thus subdivided.

A Hind-feelers much longer than the rest; jaw one-toothed; lip membranaceous, square, truncate, emargenate.

B Feelers nearly equal; jaw ciliate; lip horny, rounded, entire. This division constitutes the ascalaphus of Fabricius.

The different species inhabit the warmer parts of Europe, Africa, India, and America. The only species traced in our own country is M. formicarius; its wings clouded with brown, with a white marginal spot behind. See Nat. Hist. Pl. CLX.

MYRMIDONS, Myrmidones, in antiquity, a people on the southern borders of Thessaly, who accompanied Achilles to the Trojan war. They received the name from Myrmidon, a son of Jupiter and Eurymedusa, who married one of the daughters of Æolus, son to Helen. His son Actor married Ægina the daughter of Asopus. He gave his name to his subjects, who dwelt near the river Peneus in Thessaly. According to some, the Myrmidons received their name from their having arisen from ants or pismires, upon a prayer put up for that purpose by king Æcus to Jupiter, after his kingdom had been dispeopled by a severe pestilence. According to Strabo, they received it from their industry, because they imitated the diligence of the ants, and like them were indefatigable, and were continually employed in cultivating the earth.

MYROBALANUS (*myrobalanus*, μυροϐαλανος, from μυρο, an unguent, and ϐαλανος, a nut, so called because it was formerly used in ointments.) A myrobalan. A dried fruit, of the plum kind, brought from the East Indies. All the myrobalans have an unpleasant, bitterish, very austere taste, and strike an inky blackness with a solution of sal martis. They are said to have a gently purgative as well as an astringent and corroborating virtue. In this country they have been long expunged from the pharmacopœias.

Myrobalanus bellirica. The belliric myrobalan. This fruit is of a yellowish grey colour, and an irregularly roundish or oblong figure, about an inch in length, and three quarters of an inch thick.

Myrobalanus chebula. The chebule myrobalan. This resembles the yellow in figure and ridges, but is larger, of a darker colour inclining to brown, or blackish, and has a thicker pulp.

Myrobalanus citrina. Yellow myrobalan. This fruit is somewhat longer than the belliric, with generally five large longitudinal ridges, and as many smaller between them, somewhat pointed at both ends.

Myrobalanus emblica. The emblic myrobalan is of a dark blackish grey colour, roundish, about half an inch thick, with six hexagonal faces, opening from one another.

Myrobalanus indica. The Indian or black myrobalan, of a deep black colour, oblong, octangular, differing from all the others in having no stone, or only the rudiments of one, from which circumstance they are supposed to have been gathered before maturity.

MYROBALANS. See Myrobalanus.

MYRODENDRUM, in botany, a genus of the class polyandria, order monogynia. Calyx five-toothed; petals five; stigma five-lobed; pericarp five-celled, with a single seed in each. One species; a Cayenne tree, fifty feet high, with leaves alternate, lanceolate, acute, clasping the stem, crenate, glabrous; flowers in terminal corymbs.

MYRODIA, in botany, a genus of the class monodelphia, order polyandria. Calyx single, tubular, bursting at top; petals five; style filiform; drupe dry, two or three-celled; the cell one-seeded. Two species, shrubs of the Caribbees and of Guiana.

MYRO'POLIST. *s.* (μυρον and πωλεω.) One who feels unguents.

MYROSMA, in botany, a genus of the class monandria, order monogynia. Calyx double; the outer three-leaved, inner, three-parted; corol five-parted, irregular; capsule three-cornered, three-celled, many-seeded. One species; a Surinam shrub, growing like the canna root; fleshy, ovate; raceme like the ament of a hop, imbricate, with alternate scales of the bractes; bractes two-leaved, two-flowered.

MYROTHECIUM, in botany, a genus of the class cryptogamia, order fungi. Fungus sessile, cup-shaped; the cupola volate above; seeds rather viscid. Five species; all exotic plants.

MYROXYLON, in botany, a genus of the class decandria, order monogynia. Calyx campanulate, five-toothed; petals five, the upper ones larger than the rest: germ longer than the corol; legume one-seeded at the tip. Three species, all natives of South America; of which the following is the chief.

M. peruiferum. Balsam of Peru tree. Tree with a smooth, thick, resinous bark; leaves abruptly pinnate, in double pairs; full of linear shining resinous dots; leaflets nearly opposite, ovate-lanceolate, with an obtuse emarginate tip; racemes axillary.

The balsam obtained from this plant is extracted from it by coction, and is brought over to the consistence of thin honey, of a reddish-brown colour, inclining to black, possessing an agreeable aromatic smell, and a very hot biting taste. Distilled with water this balsam yields a small quantity of a fragrant essential oil of a reddish colour; and gives also in a strong fire a yellowish red oil. For its medical properties, see Balsamum Peruvianum.

MYRRH. (*myrrha*, Hebrew.) A botanical specimen of the tree which affords this gum-resin has not yet been obtained; but from the account of Mr. Bruce, who says it very much resembles the acacia vera, which is the mimosa nilotica of Linnéus, there can be little doubt in referring it to that genus, especially as it corresponds with the description of the tree given by Dioscorides. The tree that affords the myrrh, which is obtained by incision, grows on the eastern coast of Arabia Felix, and in that part of Abyssinia which is situated near the Red Sea, and is called by Mr. Bruce troglodite. Good myrrh is of a foul black red colour, solid and heavy, of a peculiar smell, and bitter taste. Its medicinal effects are warm, corroborant, and antiseptic; it has been successfully employed in phthisical cases as a pectoral; and although allied to some of the balsams, it is found to be more efficacious and less irritating to the system. There are several preparations of this drug in the London and Edinburgh pharmacopœias.

Myrrh fern, in botany. See Scandix.

MYRRHINE. See Murrhine.

MYRSINE, in botany, a genus of the class pentandria, order monogynia. Corol half five-cleft, connivent; germ filling the corol; drupe one-seeded, with a five-celled nut. Two species; one an African plant with elliptic acute leaves, and axillary flowers, three together, on short peduncles: and the other a plant of the Azores, with obovate, obtuse leaves, and subsessile flowers, crowded and somewhat corymbed. Both are occasionally found in our green-houses; and may be raised by planting cuttings of the young shoots in pots in summer, frequently giving them water, and restraining them to the shade.

MYRTACANTHA. (*myrtacantha*, μυρτακανθα, from μυρτος, a myrtle, and ακανθα, a thorn; so called from its likeness to myrtle, and from its prickly leaves). Butchers broom. See Ruscus.

MYRTIFORUS, in anatomy, an appellation given to several parts, because of their resembling myrtle-berries.

MYRTIFORM CARUNCLES. The remains of the hymen. See Glandule myrtiformes.

Myrtiform glands. See Glandulæ myrtiformes.

MYRTILLUS. (*myrtillus*). The berries which are directed in pharmacopœias by the name of baccæ myrtillorum are the fruit of the vaccinium myrtillus of Linnéus. Prepared with vinegar they are esteemed as antiscorbutics, and when dry possess astringent virtues.

MYRTLE, in botany. See Myrtus.

Myrtle (Candleberry). See Myrica.

Myrtle-leaved sumach. See Coriarea.

Myrto-cistus. See Hypericum.

Myrtle (Dutch). See Myrica.

MYRTUS; myrtle. In botany, a genus of the class icosandria, order monogynia; calyx four or five-cleft, superior: petals four or five; berry two or three-celled; seeds numerous, gibbous. Twenty-eight species, often, however, made more numerous from the introduction of plants that belong to other genera. These are uniformly natives of warm climates, and for the most part indigenous to India, South America, the West Indies, or the Cape. The three following are those mostly entitled to attention.

1. M. communis. Common myrtle. Flowers solitary, with a two-leaved involucre. It is a native of Asia, Africa, and the south of Europe, and the parent of all the common varieties of myrtle we meet with in our gardens and green-houses. Of these varieties the chief are:—

α. Common broad-leaved or Roman myrtle.
ϐ. Box-leaved myrtle.
γ. Common Italian or upright myrtle, of which the nutmeg myrtle is a sub-variety.
δ. Orange, or bay-leaved myrtle.
ε. Portugal myrtle.
ζ. Broad-leaved Dutch myrtle.
η. Double-flowering myrtle.
θ. Rosemary, or thyme-leaved myrtle.

All these varieties are constant; but there are others which are far less marked and more fugitive; as, for instance, the gold-striped, broad-leaved myrtle; broad-leaved Jews myrtle; gold-striped orange-leaved myrtle; silver-striped Italian myrtle; striped box-leaved myrtle; coxcomb, or birds-nest myrtle, &c.

These are all easily propagated from cuttings. The best season for this is July; and the straitest and youngest vigorous shoots are to be chosen. These should be cut off about eight inches long, and the leaves of the lower part stripped off to two inches high, and that part of the stalk twisted which is to be placed in the ground; they are to be planted in pots of light rich earth, at about two inches distance from each other, observing to close the earth very well about them, and give them a gentle watering. They are then to be removed into a moderate hot-bed, and shaded and watered once in two or three days till they have taken root. In about a month's time they will be rooted, and will begin to shoot, and must then be inured by degrees to the air; and in August they should be removed into the open air, but placed in a warm situation, and sheltered from the winds; they should stand here till October, and then be removed into a green-house, where they should be placed so as to have as much air as possible. In the March following they should be removed into separate pots of rich earth, and in May set out to the open air in a warm and well-defended place. They will require in the summer frequent waterings, and the dead leaves should be carefully picked off. As they advance in growth, they are to be shifted at times into pots of a larger size; and this should be done either in April or in August; and towards the end of October they should always be removed into the green-house.

2. M. pimenta. Pimento myrtle. A tree about fifty feet high; leaves alternate, elliptic, veined; flowers panicled on trichotomous peduncles; calyx four-cleft; petals four. The branches on the top are much divided, and possess a rich foliage, the perpetual verdure of which always gives the tree a very high degree of beauty. It is a native of New Spain and of the West-Indies. In Jamaica it grows very plentifully; and in June, July, and August, puts forth its flowers, which, with every part of the tree, breathe an aromatic fragrance. The berries, when ripe, are of a dark purple colour, and full of a sweet pulp, which the birds devour greedily. It is these dried berries that are denominated pimento, allspice, or Jamaica pepper. For their medical properties, see Pimento.

3. M. caryophyllata. Clove myrtle. Peduncles trichotomous, terminal; calyx undivided; leaves obovate, not dotted, slightly petioled. The bark of this tree has a considerable resemblance in smell and taste to the clove-spice or fruit of the eugenia caryophyllata, and are often recommended in the dispensatories on this account, under the name of Cassia caryophyllata, which see. It is a native of Ceylon.

Myrtus Brabantica. Gaule. Sweet willow, or Dutch myrtle. The leaves, flowers, and seeds of this plant, myrica gale of Linnéus, have a strong fragrant smell, and a bitter taste. They are said to be used amongst the common people for destroying moths and cutaneous insects, and the infusion is given internally as a stomachic and vermifuge.

MYSE'LF. *s.* (*my* and *self.*) 1. An emphatical word added to *I*: as, *I* myself *do it*; that is, not I by proxy; not another. 2. The reciprocal of I, in the oblique case.

MYSIA, a country of Asia Minor, generally divided into Major and Minor. Mysia Minor was bounded on the north and west by the Propontis and Bithynia, and Phrygia on the southern and eastern borders. Mysia Major had Æolia on the south, Ægean on the west, and Phrygia on the north and east. Its chief cities were Cyzicum, Lampsacus, &c. The inhabitants were once very warlike; but they greatly degenerated; and the words *Mysorum ultimus* was emphatically used to signify a person of no merit. The ancients generally hired them to attend their funerals as mourners, because they were naturally melancholy and inclined to shed tears. They were once governed by monarchs. They are supposed to be descended from the Mysians of Europe, a nation who inhabited that part of Thrace which was situated between Mount Hæmus and the Danube.

MYSON, a native of Sparta, one of the seven wise men of Greece. When Anacharsis consulted the oracle of Apollo, to know which was the wisest man in Greece, he received for answer, he who is now ploughing his fields. This was Myson.

MYSORE, a province of Hindustan, which takes its name from a town situated about ten miles south from the river Cauvery, formerly governed by an Hindu prince. What is called the kingdom of Mysore, includes, besides the Mysore Proper, the countries of Bednore, Coimbetore, Canara, and Dindigul, with some others, the whole forming an extent near 500 miles, from north to south, and near 300, where broadest, from east to west, though in some places it is hardly 100, and, towards the south, narrowed almost to a point. Mysore, on the north, is bounded by the countries of Visiapour and Golconda, on the east by the Carnatic, on the south by Madura Travancore, and Cochin, and on the west by the Indian Sea. On the death of the last Hindu king, Hyder Ally, a soldier of fortune, declared himself regent, and imprisoned the young prince, who was to have succeeded his father. Hyder had risen from a low rank, to the supreme command of the army. On a complaint that the English had not kept their treaties with him, he made an irruption into the Carnatic. The war continued with various success, during the years 1767, 1768, and part of 1769; when Hyder, with a strong detachment of chosen troops, chiefly horse, giving the British army the slip, came within seven miles of Madras, and dictated a peace to the government of that place. Some years afterwards hostilities were again commenced, and successively renewed, till the death of Hyder Ally, and even after his death, by his son Tippoo; till, in the year 1792, after several defeats, Tippoo was compelled to make peace, on the humiliating terms of surrendering great part of his dominions to the English and their friends, and the payment of thirty lacks of rupees; and for the due performance of the articles of the treaty, two of the sultan's eldest sons were sent as hostages to lord Cornwallis, the commander of the British army. The gross revenue of Tippoo has been stated at four crores of rupees, or as many millions sterling. His military establishment was very great, being no less than 72,800 regulars, including 740 Europeans, under the command of French officers: besides troops in the frontier garrisons to the amount of 49,000. The remainder of his force consisted of irregulars of various descriptions, and amounts to 33,000, and upwards; so that the whole force of Tippoo was reckoned at 155,000, of which near 73,000 were of a class much superior to any troops that have ever been raised and disciplined by a native of India.

Mysore, a fortified town of Hindustan, anciently the capital of the country so called: ten miles S. Seringapatam.

MYSTAGO'GUE *s.* (*μυϛαγωγὸς.*) One who interprets divine mysteries; also one who keeps church relics, and shows them to strangers (*Bailey*).

MYSTAX. The hair which forms the beard in man, on each side the upper lip.

MYSTE'RIARCH. *s.* (*μυϛήριον* and *αρχὴ.*) One presiding over mysteries.

MYSTE'RIOUS. *a.* (*mysterieux*, French.) 1. Inaccessible to the understanding; awfully obscure (*Denham*). 2. Artfully perplexed (*Swift*).

MYSTE'RIOUSLY. *ad.* (from *mysterious.*) 1. In a manner above understanding. 2. Obscurely; enigmatically (*Taylor*).

MYSTE'RIOUSNESS. *s.* (from *mysterious.*) 1. Holy obscurity (*Taylor*). 2. Artful difficulty or perplexity.

To MY'STERIZE. *v. a.* (from *mystery.*) To explain as enigmas (*Brown*).

MY'STERY. *s.* (*μυϛέριον*; *mystere*, French.) 1. Something above human intelligence; something awfully obscure (*Taylor*). 2. An enigma; any thing artfully made difficult (*Shakspeare*). 3. A trade; a calling: in this sense it should, according to *Warburton*, be written *mistery*, from *mestier*, French, a trade (*Shakspeare*).

Mystery, *mysterium*, something secret or hidden; impossible or difficult to be comprehended. The word comes from the Greek *μυϛηριον*; and, that according to some etymologists, from *μυω*, *claudo*, *taceo*, I shut, I am silent, and *ϛομα*, mouth; but then whence comes the *r*? Must the *m* in *ϛομα* be converted into an *r*? The word seems derived, with more propriety, from the Hebrew סתר *sator*, to hide; whence is formed מסתך *mistar*, a hidden thing.

Mystery is primarily used in speaking of certain truths revealed in scripture, into the full understanding whereof human reason cannot penetrate. Such are said to be the doctrines of the trinity, the incarnation, &c. We have an epitome of the mysteries of faith, or the mysteries of christianity, in the symbols or creeds, compiled by the apostles, the council of Nice, and St. Athanasius. (See Creed.) In some of these mention is made of the mystery of the trinity; the mysteries of the incarnation of the Son of God, his death and passion, and his descent into hell, for the redemption of mankind; of his resurrection the third day, his ascension into heaven, his sitting on the right hand of God, and his coming again to judge the world; of the divinity and coequality of the Holy Ghost with the Father and the Son; of the unity of the church; of the communion of saints; the participation of the sacraments; and the general resurrection.

It is very customary with unbelievers to affirm that they will believe nothing which they cannot comprehend, and thence to reject the christian religion. But Dr. Gregory, in his "Letters on the Evidences, Doctrines, and Duties of the Christian Religion," just published by Baldwin, has shewn that this objection is untenable, being founded in a neglect of the essential distinction between what is above reason, and what is contrary to it. He also shews, by running over the general principles of various branches of mathematical, chemical, and metaphysical science, that the difficulties attending christianity on the score of its mysterious or incomprehensible parts are of the same kind (and probably should be referred to the same cause, the weakness of our faculties) as those which envelope all the fundamental principles of knowledge. See vol. i. pa. 57—77.

The heathens also had their mysteries, particularly those of Ceres (see ELEUSINIA), the Bona Dea, &c. The Egyptian priests concealed the mysteries of their religion and philosophy under hieroglyphics. Those who revealed the mysteries of the Bona Dea were severely punished; and none were trusted with them but those solemnly initiated, and sworn to secrecy. But these were not called mysteries, as being incomprehensible, or raised above the power of reason; but because they were covered and disguised under types and figures, to raise the greater veneration in the people. The mysteries of paganism were usually celebrated in caves and grottos, fitter to conceal crimes than to celebrate mysteries in.

MY'STICAL. MY'STIC. *a.* (*mysticus*, Latin.) 1. Sacredly obscure (*Hooker*). 2. Involving some secret meaning; emblematical (*Taylor*). 3. Obscure; secret (*Dryden*).

MY'STICALLY. *ad.* (from *mystical.*) In a manner, or by an act, implying some secret meaning (*Donne*).

MY'STICALNESS. *s.* (from *mystical.*) Involution of some secret meaning.

MYSTIC THEOLOGY denotes a refined and sublime kind of divinity, professed by the mystics.

It consists in a knowledge of God, and divine things, not acquired in the common way, but infused immediately by God, and which has the power to move the soul in an easy, calm, devout, affective manner; to unite it ultimately to God; to illumine the understanding, and to warm and enliven the will, in an extraordinary manner.

Among the writings attributed to Dionysius the Areopagite, is a discourse of mystic theology. Several others have written on the same subject, both ancients and moderns.

MYSTICS, *mystici*, a kind of religious sect, distinguished by their professing pure, sublime, and perfect devotion, with an entire disinterested love of God, free from all selfish considerations.

The mystics, to excuse their fanatic ecstasies, and amorous extravagancies, allege that passage of St. Paul; The spirit prays in us by sighs and groans that are unutterable. Now, if the spirit, say they, pray in us, we must resign ourselves to its motions, and be swayed and guided by its impulse, by remaining in a state of mere inaction.

Passive contemplation is that state of perfection to which the mystics all aspire.

The authors of this mystic science, which sprung up towards the close of the third century, are not known; but the principles from which it was formed are manifest. Its first promoters proceeded from the known doctrine of the Platonic school, which was also adopted by Origen and his disciples, that the divine nature was diffused through all human souls, or that the faculty of reason, from which proceeds the health and vigour of the mind, was an emanation from God into the human soul, and comprehended in it the principles and elements of all truth, human and divine. They denied that men could by labour or study excite this celestial flame in their breasts, and, therefore, they disapproved highly of the attempts of those, who, by definitions, abstract theorems and profound speculations, endeavoured to form distinct notions of truth, and to discover its hidden nature. On the contrary, they maintained that silence, tranquillity, repose, and solitude, accompanied with such acts as might tend to extenuate and exhaust the body, were the means by which the hidden and internal word was excited to produce its latent virtues, and to instruct men in the knowledge of divine things.

MYTENS (Arnold), a painter, born at Brussels in 1541. He formed his style in the taste of the Roman school, and painted several capital pictures for churches in Italy. He died in 1602.

MYTENS (Martin), a Swedish painter, born at Stockholm in 1695, and died in 1755. He visited various countries, and had the honour to paint the portraits of several princes, particularly the czar Peter, who pressed him to settle at Petersburgh; but being bent on a journey to Italy, he declined the offer. At length he settled at Vienna, where he was held in great esteem by the emperor Charles VI. His best performance is a representation of the story of Esther and Ahasuerus (*Watk.*).

MYTHOLO'GICAL. *a.* (from *mythology.*) Relating to the explication of fabulous history (*Brown*).

MYTHOLO'GICALLY. *ad.* (from *mythological.*) In a manner suitable to the system of fables.

MYTHO'LOGIST. *s.* (from *mythology.*) A relater or expositor of the ancient fables of the heathens (*Creech. Norris*).

To MYTHO'LOGIZE. *v. n.* (from *mythology.*) To relate or explain the fabulous history of the heathens.

MYTHOLOGY is compounded of two Greek words, and in its original import it signifies any kind of fabulous doctrine: in its more appropriated sense, it means those fabulous details concerning the objects of worship which were invented and propogated by men who lived in the early ages of the world, and by them transmitted to succeeding generations, either by written records or by oral tradition.

MYTHOLOGY.

As the theology and mythology of the ancients are almost inseparably connected, it will be impossible for us to develope the latter, without often introducing some observations relating to the former. We must therefore intreat the indulgence of our readers, if upon some occasions we should hazard a few strictures on the names, characters, adventures, and functions of such pagan divinities as may have furnished materials for those fabulous narrations which the nature of the subject may lead us to discuss.

With respect to fable, it may be observed in general, that it is a creature of the human imagination, and derives its birth from that love of the marvellous which is in a manner congenial to the soul of man. The appearances of nature which every day occur, objects, actions, and events, which succeed each other, by a kind of routine, are too familiar, too obvious, and uninteresting, either to gratify curiosity or to excite admiration. On the other hand, when the most common phenomena in nature or life are new-modelled by the plastic power of a warm imagination; when they are diversified, compounded, embellished, or even arranged and moulded into forms which seldom or perhaps never occur in the ordinary course of things; novelty generates admiration, a passion always attended with delightful sensations. Here then we imagine we have discovered the very source of fiction and fable. They originated from that powerful propensity in our nature towards the new and surprising, animated by the delight with which the contemplation of them is generally attended.

Many circumstances contributed to extend and establish the empire of fable. The legislator laid hold on this bias of human nature, and of course employed fable and fiction as the most effectual means to civilize a rude, unpolished world. The philosopher, the theologist, the poet, the musician, each in his turn, made use of this vehicle to convey his maxims and instructions to the savage tribes. They knew that truth, simple and unadorned, is not possessed of charms powerful enough to captivate the heart of man in his present corrupt and degenerate state. This consideration, which did indeed result from the character of their audience, naturally led them to employ fiction and allegory. From this was derived the allegorical taste of the ancients, and especially of the primary sages of the east.

Though almost every nation on the face of the globe, however removed from the centre of population, however savage and averse from cultivation, has fabricated and adopted its own system of mythology; the Orientals, however, have distinguished themselves in a peculiar manner, by the boldness, the inconsistency, and the extravagance of their mythology. The genial warmth of those happy climes, the fertility of the soil, which afforded every necessary, every conveniency, and often every luxury of life, without depressing their spirits by laborious exertions; the face of nature perpetually blooming around them, the skies smiling with uninterrupted serenity; all contributed to inspire the orientals with a glow of fancy and a vigour of imagination rarely to be met with in less happy regions. Hence every object was swelled beyond its natural dimensions. Nothing was great or little in moderation, but every sentiment was heightened with incredible hyperbole. The magnificent, the sublime, the vast, the enormous, the marvellous, first sprung up, and were brought to maturity, in those native regions of fable and fairy-land. As nature, in the ordinary course of her operations, exhibited neither objects nor effects adequate to the extent of their romantic imaginations, they naturally deviated into the fields of fiction and fable. Of consequence, the custom of detailing fabulous adventures originated in the east, and was from thence transplanted into the western countries.

As the allegorical taste of the eastern nations had sprung from their propensity to fable, and as that propensity had in its turn originated from the love of the marvellous; so did allegory in process of time contribute its influence towards multiplying fables and fiction almost *in infinitum*. The latent import of the allegorical doctrines being in a few ages lost and obliterated, what was originally a moral or theological tenet assumed the air and habit of a personal adventure.

The propensity towards personification, almost universal among the orientals, was another fruitful source of fable and allegory. That the people of the east were strongly inclined to personify inanimate objects and abstract ideas, we imagine will be readily granted, when it is considered, that in the formation of language they have generally annexed the affection of sex to those objects. Hence the distinction of grammatical genders, which is known to have originated in the eastern parts of the world. The practice of personifying virtues, vices, religious and moral affections, was necessary to support that allegorical style which universally prevailed in those countries. This mode of writing was in high reputation even in Europe some centuries ago; and to it we are indebted for some of the most noble poetical compositions now extant in our own language. Those productions, however, are but faint imitations of the original mode of writing still current among the eastern nations. The Europeans derived this species of composition from the Moorish inhabitants of Spain, who imported it from Arabia, their original country.

The general use of hieroglyphics in the East must have contributed largely towards extending the empire of mythology. As the import of the figures employed in this method of delineating the signs of ideas was in a great measure arbitrary, mistakes must have been frequently committed in ascertaining the notions which they were at the first intended to represent. When the development of these arbitrary signs happened to be attended with uncommon difficulty, the expounders were obliged to have recourse to conjecture. Those conjectural expositions were for the most part tinctured with that bias towards the marvellous which universally prevailed among the primitive men. This we find is the case even at this day, when moderns attempt to develop the purport of emblematical figures, preserved on ancient medals, intaglios, &c.

The wise men of the East delighted in obscure enigmatical sentences. They seem to have disdained every sentiment obvious to vulgar apprehension. The words of the wise, and their dark sayings, often occurred in the most ancient records both sacred and profane. The sages of antiquity used to vie with each other for the prize of superior wisdom, by propounding riddles, and dark and mysterious questions, as subjects of investigation. The contest between Solomon and Hiram, and that between Amasis king of Egypt and Polycrates tyrant of Samos, are universally known.— As the import of those enigmatical propositions was often absolutely lost, in ages when the art of writing was little known, and still less practised, nothing remained but fancy and conjecture, which always verged towards the regions of fable. This then, we think, was another source of mythology.

The pagan priests, especially in Egypt, were probably the first who reduced mythology to a kind of system. The sacerdotal tribe, among that people, were the grand depositaries of learning, as well as of religion. That order of men monopolised all the arts and sciences. They seemed to have formed a conspiracy among themselves, to preclude the laity from all the avenues of intellectual improvement. This plan was adopted with a view to keep the laity in subjection, and to enhance their own importance. To accomplish this end, they contrived to perform all the ministrations of their religion in an unknown tongue, and to cover them with a thick veil of fable and allegory. The language of Ethiopia became their sacred dialect, and hieroglyphics their sacred character. Egypt, of course, became a kind of fairyland, where all was jugglery, magic, and enchantment. The initiated alone were admitted to the knowledge of the occult mystical exhibitions, which, in their hands, constituted the essence of their religion. From these the vulgar and profane were prohibited by the most rigorous penalties. The Egyptians, and indeed all the ancients without exception, deemed the mysteries of religion too sacred and solemn to be communicated to the herd of mankind, naked and unreserved; a mode by which they imagined those sacred and sublime oracles would have been defiled and degraded. *Procul, o procul este profani —Odi profanum vulgus et arceo.* Egypt was the land of graven images; allegory and mythology were the veil which concealed religion from the eyes of the vulgar; fable was the ground-work of that impenetrable covering.

In the earliest and most unpolished state of society we cannot suppose fable to have existed among men. Fables are always tales of other times, but at this period other times did not reach far enough backward to afford those fruits of the imagination sufficient time to arrive at maturity. Fable requires a considerable space of time to acquire credibility, and to rise into reputation. Accordingly, we find that both the Chinese and Egyptians, the two most ancient nations whose annals have reached our times, were altogether unacquainted with fabulous details in the most early and least improved periods of their respective monarchies. It has been shown almost to a demonstration, by a variety of learned men, that both the one and the other people, during some centuries after the general deluge, retained and practised the primitive Noachic religion, in which fable and fancy could find no place; all was genuine unsophisticated truth.

As soon as the authentic tradition concerning the origin of the universe was either in a good measure lost, or at least adulterated by the inventions of men, fable and fiction began to prevail. The Egyptian Thoth or Thyoth, or Mercury Trismegistus, and Mochus the Phœnician, undertook to account for the formation and arrangement of the universe, upon principles purely mechanical. Here fable began to usurp the place of genuine historical truth. Accordingly, we find that all the historians of antiquity, who have undertaken to give a general detail of the affairs of the world, have ushered in their narration with a fabulous cosmogony. Here imagination ranged unconfined over the boundless extent of the primary chaos. To be convinced of the truth of this assertion, we need only look into Sanchoniathon's Cosmogony, Euseb. Præp. Evang. l. 1. sub init. and Diodorus Sic. l. 1. From this we suppose it will follow, that the first race of fables owed their birth to the erroneous opinions of the formation of the universe.

Having now endeavoured to point out the origin of mythology, or fabulous traditions, we shall proceed to lay before our readers a brief detail of the mythology of the most respectable nations of antiquity, following the natural order of their situation.

According to the Chinese accounts, Fohe or Fohi laid the foundation of that empire about 4000 years ago. This emperor, according to the Chinese, was conceived in a miraculous manner. His mother, say they, one day as she was walking in a desert place, was surrounded by a rainbow; and, being impregnated by this meteor, was in due time delivered of that celebrated legislator. This personage, like the Athenian Cecrops, was half a man and half a serpent. His intellectual powers were truly hyperbolical. In one day he discovered 50 different species of poisonous herbs. He taught his countrymen the whole art of agriculture in the space of a very few years. He instructed them how to sow five different sorts of grain. He invented boats and nets for fishing, the art of fabricating porcelain, the management of silk-worms, the manufacturing of silk, &c. In a word, that wonderful personage was inspired by Heaven with knowledge, which qualified him for composing that incomparable body of laws which are even at this day the wonder of the world. Our readers will admit, that this whole detail is fabulous and chimerical. The most learned part of them will readily observe, that the Chinese, in ascribing the invention of all the useful arts to their Fohi, are perfectly agreed with almost all the other nations of antiquity. The Indians ascribe every invention to Budha, or Vishnou, or Foe; the Persians to Zerdusht or Zoroastres; the Chaldeans to their man of the sea, whom they call Oannes; the Egyptians to Thoth or Thyoth; the Phœnicians to Melicerta; the Greeks to the family of the Titans; and the Scandinavians to Odin; &c.

About 551 years before the Christian æra, appeared the famous Chinese philosopher Con-fu-tse, or Confucius. Concerning the birth of this prince of philosophers, the Chinese have propagated the following legendary tale. His mother walking in a solitary place was impregnated by the vivifying influence of the Heavens. The babe, thus produced, spake and reasoned as soon as it was born. Confucius, however, wrought no miracles, performed no romantic exploits, but lived an austere ascetic life, taught and inculcated the doctrines of pure morality, and died, remarkable only for superior wisdom, religious, moral, and political.

About the year of Christ 601, flourished the sectary Laokiun. His mother carried him 30 years in her womb, and was at last delivered of him under a plum-tree. This philosopher was the Epicurus of the Chinese. His disciples, who were denominated Fao-sse, i. e. heavenly doctors, were the first who corrupted the religion of the Chinese. They were addicted to magic, and introduced the worship of good and bad dæmons. Their doctrine was embraced by a long succession of emperors. One of these princes, called You-ti, had been deprived by death of a favourite mistress, whom he loved with the most extravagant passion. The emperor, by the magical skill of one of these doctors, obtained an interview with his deceased mistress, a circumstance which riveted the whole order in the affection and esteem of the deluded prince. Here our readers will observe the exact counterpart of the fable of Eurydice, so famous in the mythology of the Greeks and Romans. That such a system of religious principles must have abounded with mythological adventures is highly probable; but as the missionaries, to whom we are chiefly indebted for our information relating to the religion of the Chinese, have not taken the pains to record them, we find it impossible to gratify the curiosity of our readers on that head.

The worship of the idol Fo, or Foe, was transplanted from India into China about the 56th year of the Christian æra, upon the following occasion. One of the doctors of the Fao-sse had promised a prince of the family of Tchou, and brother of the emperor Ming-ti, to make him enter into communion with the spirits. At his solicitation an ambassador was dispatched into India, in order to enquire where the true religion was to be found. There had been a tradition, say the missionaries, ever since the age of Confucius, that the true religion was to be found in the west.—The ambassador stopt short in India; and finding that the god Foe was in high reputation in that country, he collected several images of that deity painted on chintz, and with it 42 chapters of the canonical books of the Hindus, which, together with the images, he laid on a white elephant, and transported into his native country. At the same time he imported from the same quarter the doctrine of the transmigration of souls, which is firmly believed in China to this day. The doctrine and worship of Foe, thus introduced, made a most rapid progress all over China, Japan, Siam, &c. The priests of Foe are called among the Siamese, Talopoins; by the Tartars, Lamas; by the Chinese, Ho-chang; and by the people of Japan, Bonzes. By this last appellation they are generally known in Europe.

An infinitude of fable was invented and propagated by the disciples of Foe, concerning the life and adventures of their master. If the earlier ages of the Chinese history are barren of mythological incidents, the later periods, after the introduction of the worship of Foe, furnish an inexhaustible store of miracles, monsters, fables, intrigues, exploits, and adventures, of the most villanous complexion. Indeed, most of them are so absurd, so ridiculous, and at the same time so impious and profane, that we are convinced our readers will easily dispense with a detail from which they could reap neither entertainment nor instruction. Such as may find themselves disposed to rake into this abominable puddle we must refer to the reverend fathers Du Halde, Couplet, Amiot, Kircher, and other members of the propaganda, in whose writings they will find wherewithal to satisfy, and even to surfeit, their appetite.

The Hindus, like the other nations of the East, for a long time retained the worship of the true God. At length, however, idolatry broke in, and, like an impetuous torrent, overwhelmed the country. First of all, the genuine history of the origin of the universe was either utterly lost, or disguised under a variety of fictions and allegories. We are told that Brimha, the supreme divinity of the Hindus, after three several efforts, at last succeeded in creating four persons, whom he appointed to rule over all the inferior creatures.—Afterwards Brimha joined his efficient power with Bishon and Rulder; and by their united exertions they produced ten men, whose general appellation is Munies, that is, the inspired. The same being, according to another mythology, produced four other persons, as imaginary as the former; one from his breast, one from his back, one from his lip, and one from his heart. These children were denominated Bangs; the import of which word we cannot pretend to determine. According to another tradition, Brimha produced the Bramins from his mouth, to pray, to read, to instruct; the Chiltern from his arms, to draw the bow, to fight, to govern; the Bice from his belly or thighs, to nourish, to provide the necessaries of life by agriculture and commerce; the Sodor from his feet, for subjection, to serve, to labour, to travel. The reader will see at once, in these allegorical persons, the four casts or septs into which the Hindu nations have, time immemorial, been divided. These are some of their most celebrated mythological traditions with relation to the origin of the universe.

The Hindus have likewise some mythological opinions which seem to relate to the general deluge. They tell us, that desiring the preservation of herds and of brahmans, of genii and of virtuous men, of vedas of law, and of precious things, the Lord of the universe assumes many bodily shapes; but though he pervades, like the air, a variety of beings, yet he is himself unvaried, since he has no quality in him subject to change. At the close of the last calpa, there was a general destruction, occasioned by the sleep of Brahme, whence his creatures in different worlds were drowned in a vast ocean. Brahme being inclined to slumber after a lapse of so many ages, the strong dæmon Hayagri-va came near him, and stole the vedas which had flowed from his lips. When Heri, the preserver of the universe, discovered this deed of the prince of Dainavas, he took the shape of a minute fish called Sap-hari. After various transformations, and an enormous increase of size in each of them, the Lord of the universel oving the righteous man, who had still adhered to him under all these various shapes, and intending to preserve him from the sea of destruction caused by the depravity of the age, thus told him how he was to act: "In seven days from the present time, O thou tamer of enemies! the three worlds will be plunged in an ocean of death; but in the midst of the destroying waves a large vessel sent by me for thy use shall stand before thee." The remaining part of the mythology so nearly resembles the Mosaic history of Noah and the general deluge, that the former may be a strong confirmation of the truth of the latter. To dry up the waters of the deluge, the power of the Deity descends in the form of a boar, the symbol of strength, to draw up and support on its tusks the whole earth, which had been sunk beneath the ocean. Again, the same power is represented as a tortoise sustaining the globe, which had been convulsed by the violent assaults of dæmons, while the gods charmed the sea, with the mountain Mandar, and forced it to disgorge the sacred things and animals, together with the water of life which it had swallowed. All these stories, we think, relate to the same event, shadowed by a moral, a metaphysical, and an astronomical allegory; and all three seem connected with the hieroglyphical sculptures of the old Egyptians.

The Hindus divide the duration of the world into four Yugs or Jugs, or Jogues, each consisting of a prodigious number of years. In each of those periods, the age and stature of the human race have been gradual diminished; and in each of them mankind has gradually declined in virtue and piety, as well as in age and stature. The present period they call the Collæ, i. e. the corrupt Jogue, which they say is to last 400,000 years, of which near 5000 years are already past. In the last part of the preceding Jogue, which they call the Dwa paar, the age of man was contracted into 1000 years, as in the present it is confined to 100. From this proportional diminution of the length of the human life, our readers will probably infer, that the two last Jogues bear a pretty near resemblance to the Mosaic history of the age of the antediluvian and postdiluvian patriarchs; and that the two first are imaginary periods prior to the creation of the world, like those of the Chinese, Chaldeans, and Egyptians.

According to the mythology of the Hindus, the system of the world is subject to various dissolutions and resuscitations. At the conclusion of the Collæ Jogue, say they, a grand revolution will take place, when the solar system will be consumed by fire, and all the elements reduced to their original constituent atoms. Upon the back of these revolutions, Brimha, the supreme deity of the Hindus, is sometimes represented as a new-born infant, with his toe in his mouth, floating on a camala or water flower, sometimes only on a leaf of that plant, on the surface of the vast abyss. At other times he is figured as coming forth of a winding shell; and again as blowing up the mundane foam with a pipe at his mouth. Some of these emblematical figures and attitudes, our learned readers will probably observe, nearly resemble those of the ancient Egyptians.

But the vulgar religion of the ancient Hindus was of a very different complexion, and opens a large field of mythological adventures. We have observed above, that the Fo or Foe of the Chinese was imported from India; and now we shall give a brief detail of the mythological origin of that divinity. We have no certain account of the birth-place of this imaginary deity.—His followers relate, that he was born in one of the kingdoms of India near the line, and that his father was one of that country. His mother brought him into the world by the left side; and expired soon after the delivery. At the time of her conception, she dreamed that she had swallowed a white elephant; a circumstance which is supposed to have given birth to the veneration which the kings of India have always shown for a white animal of that species. As soon as he was born, he had strength enough to stand erect without assistance. He walked abroad at seven, and, pointing with one hand to the heavens, and with the other to the earth, he cried out, "In the heavens, and on the earth, there is no one but me who deserves to be honoured." At the age of 30, he felt himself all on a sudden filled with the divinity; and now he was metamorphosed into Fo or Pagod, according to the expression of the Hindus. He had no sooner declared himself a divinity, than he thought of propagating his doctrine, and proving his divine mission by miracles. The number of his disciples was immense; and they soon spread his dogmas over all India, and even to the higher extremities of Asia.

One of the principal doctrines which Fo and his disciples propagated, was the metempsychosis or transmigration of souls. This doctrine, some imagine, has given rise to the multitude of idols reverenced in every country where the worship of Fo is established. Quadrupeds, birds, reptiles, and the vilest animals, had temples erected for them; because, say they, the soul of the god, in his numerous transmigrations, may have, at one time or other, inhabited their bodies.

Both the doctrine of transmigration and of the worship of animals seems, however, to have been imported from Egypt into India. If the intercourse between these two countries was begun at so early a period as some very late writers have endeavoured to prove, such a supposition is by no means improbable. The doctrine of the transmigration of souls was early established among the Egyptians. It was, indeed, the only idea they formed of the soul's immortality. The worship of animals among them seems to have been still more ancient. If such an intercourse did actually exist, we may naturally suppose that colonies of Egyptian priests found their way into India, as they did afterwards into Asia Minor, Italy, and Greece. That colonies of Egyptians did actually penetrate into that country, and settle there, many centuries before the Nativity, is a fact that cannot be called in question, for reasons which the bounds prescribed us on this article will not allow us to enumerate. We shall only observe, that from the hieroglyphical representations of the Egyptian deities seem to have originated those monstrous idols which from time immemorial have been worshipped in India, China, Japan, Siam, and even in the remotest parts of Asiatic Tartary.

Foe is often called Budha, Budda, and sometimes Vishnou; perhaps, indeed, he may be distinguished by many other names, according to the variety of dialects of the different nations among which his worship was established. An infinitude of fables was propagated by his disciples concerning him after his death. They pretended that their master was still alive; that he had been already born 8000 times; and that he had successively appeared under the figure of an ape, a lion, a dragon, an elephant, a boar, &c. These were called the incarnations of Vishnou. At length he was confounded with the supreme God; and all the titles, attributes, operations, perfections and ensigns of the Most High were ascribed to him. Sometimes he is called Amida, and represented with the head of a dog, and worshipped as the guardian of mankind. He sometimes appears as a princely personage, issuing from the mouth of a fish. At other times, he wears a lunette on his head, in which are seen cities, mountains, towers, trees, in short, all that the world contains. These transformations are evidently the children of allegorical or hieroglyphical emblems, and form an exact counterpart to the symbolical worship of the Egyptians.

The enormous mass of mythological traditions which have in a manner deluged the vast continent of India would fill many volumes: we have selected the preceding articles as a specimen only, by which our readers may be qualified to judge of the rest. If they find themselves disposed to indulge their curiosity at greater length, we must remit them to Thevenot's and Hamilton's Travels, to Mons. Aquetil in his Zond Avesta; Halhed's Introduction to his translation of the Code of Gentoo Laws; Col. Dow's History of Hindostan; Grose's Voyage to the East Indies; Asiatic Researches, vol. I. and II.

The mythology of the Persians is, if possible, still more extravagant than that of the Hindus. It supposes the world to have been repeatedly destroyed, and repeopled by creatures of different formation, who were successively annihilated or banished for their disobedience to the Supreme Being. The monstrous griffin Sinergh tells the hero Caherman that she had already lived to see the earth seven times filled with creatures, and seven times a perfect void; that before the creation of Adam, this globe was inhabited by a race of beings called Peri and Dives, whose character formed a perfect contrast. The Peri are described as beautiful and benevolent; the Dives as deformed, malevolent, and mischievous, differing from infernal demons only in this, that they are not as yet confined to the pit of hell. They are for ever ranging over the world, to scatter discord and misery among the sons of men. The Peri nearly resemble the fairies of Europe; and perhaps the Dives gave birth to the giants and magicians of the middle ages. The Peri and Dives wage incessant wars; and when the Dives make any of the Peri prisoners, they shut them up in iron cages, and hang them on the highest trees, to expose them to public view, and to the fury of every chilling blast.

When the Peri are in danger of being overpowered by their foes, they solicit the assistance of some mortal hero; which produces a series of mythological adventures, highly ornamental to the strains of the Persian bards, and which, at the same time, furnishes an inexhaustible fund of the most diversified machinery.

One of the most celebrated adventurers in the mythology of Persia is Tahmurus, one of their most ancient monarchs. This prince performs a variety of exploits, while he endeavours to recover the fairy Merjan. He attacks the Dive Demrush in his own cave; where, having vanquished the giant or demon, he finds vast piles of hoarded wealth: these he carries off with the fair captive. The battles, labours, and adventures of Rostan, another Persian worthy, who lived many ages after the former, are celebrated by the Persian bards with the same extravagance of hyhyperbole with which the labours of Hercules have been sung by the poets of Greece and Rome.

The adventures of the Persian heroes breathe all the wildness of achievement recorded of the knights of Gothic romance. The doctrine of enchantments, transformations, &c. exhibited in both, is a characteristic symptom of one common original. Persia is the genuine classic ground of eastern mythology, and the source of the ideas of chivalry and romance; from which they were propagated to the regions of Scandinavia, and indeed to the remotest corners of Europe towards the west.

Perhaps our readers may be of our opinion, when we offer it as a conjecture, that the tales of the war of the Peri and Dives originated from a vague tradition concerning good and bad angels: nor is it, in our opinion, improbable, that the fable of the wars between the gods and giants, so famous in the mythology of Greece and Italy, was imported into the former of these countries from the same quarter. For a more particular account of the Persian mythology, our readers may consult Dr. Hyde de Relig. vet. Pers. Medor, &c.; D'Herbelot's Bibl. Orient. and Mr. Richardson's Introduction to his Persian and Arabic Dictionary.

The mythology of the Chaldeans, like that of the other nations of the East, commences at a period myriads of years prior to the æra of the Mosaic creation. Their cosmogony, exhibited by Berosus, who was a priest of Belus, and deeply versed in the antiquities of his country, is a piece of mythology of the most extravagant nature. It has been copied by Eusebius (Chron. l. i. p. 5.); it is likewise to be found in Syncellus, copied from Alexander Polyhistor. According to this historian, there were at Babylon written records preserved with the greatest care, comprehending a period of fifteen myriads of years. Those writings likewise contained a history of the heavens and the sea, of the earth, and of the origin of mankind. "In the beginning (says Berosus, copying from Oannes, of whom we shall give a brief account below) there was nothing but darkness and an abyss of water, wherein resided most hideous beings produced from a twofold principle. Men appeared with two wings; some with two and some with four faces. They had one body, but two heads; the one of a man, the other of a woman. Other human figures were to be seen, furnished with the legs and horns of goats. Some had the feet of horses behind, but before were fashioned like men, resembling hippocentaurs." The remaining part of this mythology is much of the same complexion; indeed so extravagant, that we imagine our readers will readily enough dispense with our translating the sequel. "Of all these (says the author) were preserved delineations in the temple of Belus at Babylon. The person who was supposed to preside over them was called Omorea. This word, in the Chaldean language, is Thalath, which the Greeks call ϑαλασσα, but it more properly imports the moon. Matters being in this situation, their god (says Eusebius), the god (says Syncellus) came and cut the woman asunder; and out of one half of her he formed the earth, and out of the other he made the heavens; and, at the same time, he destroyed the monsters of the abyss." This whole mythology is an allegorical history copied from hieroglyphical representations, the real purport of which could not be decyphered by the author. Such, in general, were the consequences of the hieroglyphical style of writing.

Oannes the great civilizer and legislator of the Chaldeans, according to Apollodorus, who copied from Berosus, was an amphibious animal of a heterogeneous appearance. He was endowed with reason, and a very uncommon acuteness of parts. His whole body resembled a fish. Under the head of a fish he had also another head, and feet below similar to those of a man, which were subjoined to the tail of the fish. His voice and language were articulate and perfectly intelligible, and there was a figure of him still extant in the days of Berosus. He made his appearance in the Erythrean or Red Sea, where it borders upon Babylonia. This monstrous being conversed with men by day; but at night he plunged into the sea, and remained concealed in the water till next morning. He taught the Babylonians the use of letters and the knowledge of all the arts and sciences. He instructed them in the method of building houses, constructing temples, and all other edifices. He taught them to compile laws and religious ceremonies, and explained to them the principles of mathematics, geometry, and astronomy. In a word, he communicated to them every thing necessary, useful, and ornamental: and so universal were his instructions, that not one single article had ever been added to them since the time they were first communicated. Helladius is of opinion that this strange personage, whoever he was, came to be represented under the figure of a fish, not because he was actually believed to be such, but because he was clothed with the skin of a seal. By this account our readers will see that the Babylonian Oannes is the exact counterpart of the Fohi of the Chinese, and the Thyoth or Mercury Trismegistus of the Egyptians. It is likewise apparent, that the idea of the monster compounded of the man and the fish has originated from some hieroglyphic of that form grafted upon the appearance of man. Some modern mythologists have been of opinion, that Oannes was actually Noah the great preacher of righteousness; who, as some think, settled in Shinar or Chaldea after the deluge, and who, in consequence of his connection with that event, might be properly represented under the emblem of the Man of the Sea.

The nativity of Venus, the goddess of beauty and love, is another piece of mythology famous among the Babylonians and Assyrians. An egg, say they, of a prodigious size, dropped from heaven into the river Euphrates. Some doves settled upon this egg, after that the fishes had rolled it to the bank. In a short time this egg produced Venus, who was afterwards called the Dea Syria, the Syrian goddess. In consequence of this tradition (says Hyginus), pigeons and fishes became sacred to this goddess among the Syrians, who always abstained from eating the one or the other. Of this imaginary being we have a very exact and entertaining history in the treatise De Dea Syria, generally ascribed to Lucian.

In this mythological tradition our readers will probably discover an illusion to the celebrated Mundane egg; and at the same time the story of the fishes will lead them to anticipate the connection between the sea and the moon. This same deity was the Atargatis of Ascalon, described by Diodorus the Sicilian; the one half of her body a woman, and the other a fish. This was no doubt a hieroglyphic figure of the moon, importing the influence of that planet upon the sea and the sex. The oriental name of this deity evidently points to the moon; for it is compounded of two Hebrew words, which import "the queen of the host of heaven."

The fable of Semiramis is nearly connected with the preceding one. Diodorus Siculus has preserved the mythological history of this deity, which he and all the writers of antiquity have confounded with the Babylonian princess of the same name. That historian informs us, that the word Semiramis, in the Syrian dialect, signifies "a wild pigeon;" but we apprehend that this term was a name or epithet of the moon, as it is compounded of two words of an import naturally applicable to the lunar planet. It was a general practice among the Orientals to denominate their sacred animals from that deity to which they were consecrated. Hence the moon being called Simiramis, and the pigeon being sacred to her divinity, the latter was called by the name of the former.

As the bounds prescribed this article renders it impossible for us to do justice to this interesting piece of mythology, we must beg leave to refer our readers for farther information to Diod. Sic. l. ii. Hyginus Poet. Astron. fab. 197. Pharnutus de Nat. Deor. Ovid. Metam. l. iv. Athen. in Apol. Izetzes Chil. ix. cap. 275. Seld. de Diis Syr. Syrit. ii. p. 183.

We should now proceed to the mythology of the Arabians, the far greatest part of which is, however, buried in the abyss of ages; though, when we reflect on the genius and character of that people, we must be convinced that they too, as well as the other nations of the East, abounded in fabulous relations and romantic compositions. The natives of that country have always been enthusiastically addicted to poetry, of which fable is the essence. Wherever the muses have erected their throne, fables and miracles have always appeared in their train. In the Koran we meet with frequent allusions to well-known traditionary fables. These had been transmitted from generation to generation by the bards and rhapsodists for the entertainment of the vulgar. In Arabia, from the earliest ages, it has always been one of the favourite entertainments of the common people to assemble in the serene evenings around their tents, or on the platforms with which their houses are generally covered, or in large halls erected for the purpose, in order to amuse themselves with traditional narrations of the most distinguished actions of their most remote ancestors. Oriental imagery always embellished their romantic details. The glow of fancy, the love of the marvellous, the propensity towards the hyperbolical and the vast, which constitute the essence of oriental description, must ever have drawn the relation aside into the devious regions of fiction and fairyland. The religion of Mahomet beat down the original fabric of idolatry and mythology together. The Arabian fables current in modern times are borrowed or imitated from Persian compositions; Persia being still the grand nursery of romance in the East.

In Egypt we find idolatry, theology, and mythology, almost inseparably blended together. The inhabitants of this region, too, as well as of others in the vicinity of the centre of population, adhered for several centuries to the worship of the true God. At last, however, conscious of their own ignorance, impurity, imperfection, and total unfitness to approach an infinitely perfect being, distant, as they imagined, and invisible, they began to cast about for some beings more exalted and more perfect than themselves, by whose mediation they might prefer their prayers to the supreme majesty of heaven. The luminaries of heaven, which they imagined were animated bodies, naturally presented themselves. These were splendid and glorious beings. They were thought to partake of the divine nature: they were revered as the satraps, prefects, and representatives of the supreme Lord of the universe. They were visible, they were beneficent; they dwelt nearer to the gods, they were near at hand, and always accessible. These were, of course, employed as mediators and intercessors between the supreme divinity and his humble subjects of this lower world. Thus employed, they might claim a subordinate share of worship, which was accordingly assigned them. In process of time, however, that worship, which was originally addressed to the supreme Creator by the mediation of the heavenly bodies, was in a great measure forgotten, and the adoration of mankind ultimately terminated on those illustrious creatures. To this circumstance, we think, we may ascribe the origin of that species of idolatry called Sabaeism, or the worship of the host of heaven, which overspread the world early and almost universally. In Egypt this mode of worship was adopted in all its most absurd and most enthusiastic forms; and at the same time the most heterogeneous mythology appeared in its train. The mythology of the ancient Egyptians was so various and multiform, so complicated and so mysterious, that it would require many volumes even to give a superficial account of its origin and progress, not only in its mother country, but even in many other parts of the eastern and western world. Besides, the idolatry and mythology of that wonderful country are so closely connected and so inseparably blended together, that it is impossible to describe the latter without at the same time developing the former. We hope, therefore, our readers will not be disappointed if, in a work of this nature, we touch only upon some of the leading or most interesting articles of this complicated subject.

The Egyptians confounded the revolutions of the heavenly bodies with the reigns of their most early monarchs. Hence the incredible number of years included in the reign of their eight superior gods, who, according to them, filled the Egyptian throne successively in the most early periods of time. To these, according to their system, succeeded twelve demigods, who likewise reigned an amazing number of years. These imaginary reigns were no other than the periodical revolutions of the heavenly bodies preserved in their almanacks, which might be carried back, and actually were carried back, at pleasure. Hence the fabulous antiquity of that kingdom. The imaginary exploits and adventures of these gods and demigods furnished an inexhaustible fund of mythological romances. To the demigods succeeded the kings of the cynic cycle, personages equally chimerical with the former. The import of this epithet has greatly perplexed critics and etymologists. We apprehend it is an oriental word importing royal dignity, elevation of rank. This appellation intimated, that the monarchs of that cycle, admitting that they actually existed, were more powerful and more highly revered than their successors. After the princes of the cynic cycle comes another race, denominated Nekyes, a title likewise implying royal, splendid, glorious. These cycles figure high in the mythological annals of the Egyptians, and have furnished materials for a variety of learned and ingenious disquisitions. The wars and adventures of Osiris, Orus, Typhon, and other allegorical personages who figure in the Egyptian rubric; the wanderings of Isis, the sister and wife of Osiris; the transformation of the gods into divers kinds of animals; their birth, education, peregrinations, and exploits; compose a body of mythological fictions so various, so complicated, so ridiculous, and often so apparently absurd, that all attempts to develope and explain them have hitherto proved unsuccessful. All, or the greatest part, of those extravagant fables are the offspring of hieroglyphical or allegorical emblems devised by the priests and sages of that nation, with a view to conceal the mysteries of their religion from that class of men whom they stigmatized with the name of the uninitiated rabble.

The worship of brute animals and of certain vegetables, universal among the Egyptians, was another exuberant source of mythological adventures. The Egyptian priests, many of whom were likewise profound philosophers, observed, or pretended to observe, a kind of analogy between the qualities of certain animals and vegetables, and those of some of their subordinate divinities. Such animals and vegetables they adopted, and consecrated to the deities to whom they were supposed to bear this anological resemblance; and in process of time they considered them as the visible emblems of those divinities to which they were consecrated. By these the vulgar addressed their archetypes: in the same manner, as in other countries, pictures and statues were employed for the very same purpose. The mob, in process of time, forgetting the emblematical character of those brutes and vegetables, addressed their devotion immediately to them; and of course these became the ultimate objects of vulgar adoration.

After that these objects, animate or inanimate, were consecrated as the visible symbols of the deities, it soon became fashionable to make use of their figures to represent those deities to which they were consecrated. This practice was the natural consequence of the hieroglyphical style which universally prevailed among the ancient Egyptians. Hence Jupiter Ammon was represented under the figure of a ram, Apis under that of a cow, Osiris of a bull, Pan of a goat, Thoth or Mercury of an ibis, Bubastis or Diana of a cat, &c. It was likewise a common practice among those deluded people to dignify these objects, by giving them the names of those deities which they represented. By this mode of dignifying these sacred emblems, the veneration of the rabble was considerably enhanced, and the ardour of their devotion inflamed in proportion. From these two sources, we think, are derived the fabulous transformations of the gods, so generally celebrated in the Egyptian mythology, and from it imported into Greece and Italy. In consequence of this practice, their mythological system was rendered at once enormous and unintelligible.

Their Thoth, or Mercury Trismegistus, was, in our opinion, the inventor of this unhappy system. This personage, according to the Egyptians, was the original author of letters, geometry, astronomy, music, architecture; in a word, of all the elegant and useful arts, and of all the branches of science and philosophy. He it was who first discovered the analogy between the divine affections, influences, appearances, operations, and the corresponding properties, qualities, and instincts of certain animals, and the propriety of dedicating particular kinds of vegetables to the service of particular deities.

The priests, whose province it was to expound the mysteries of that allegorical hieroglyphical religion, (see MYSTERY), gradually lost all knowledge of the primary import of the symbolical characters. To supply this defect, and at the same time to veil their own ignorance, the sacerdotal instructors had recourse to fable and fiction. They heaped fable upon fable, till their religion became an accumulated chaos of mythological absurdities.

Two of the most learned and most acute of the ancient philosophers have attempted a rational explication of the latent import of the Egyptian mythology; but both have failed in the attempt; nor have the moderns, who have laboured in the same department, performed their part with much better success. Instead, therefore, of prosecuting this inexplicable subject, which would swell this article beyond all proportion, we must beg leave to refer those who are desirous of further information to the following authors, where they will find enough to gratify their curiosity, if not to inform their judgment: Herodotus, lib. ii. Diodorus Siculus, lib. 1. Plut. Isis & Osiris; Jamblichus de Myst. Ægypt. Horapollo Hieroglyph. Egypt. Macrob. Sat. cap. 23. among the ancients: and among the moderns, Kircher's Œdip. Voss. de Origin. et Prog. Idol. Mr. Bryant's Analysis of Anc. Mythol. Mons. Gebelin, Monde prim.; and above all, to the learned Jablonski's Panth. Ægyptiorum.

The elements of Phœnician mythology have been preserved by Eusebius, Præp. Evang. sub init. In the large extract which that learned father hath copied from Philo Biblius's translation of Sanchoniatho's history of Phœnicia, we are furnished with several articles of mythology. Some of these throw considerable light on several passages of the sacred history; and all of them are strictly connected with the mythology of the Greeks and Romans. There we have preserved a brief but entertaining detail of the fabulous adventures of Uranus, Cronus, Dagon, Thyoth or Mercury, probably the same with the Egyptian hero of that name. Here we find Muth or Pluto, Æphcestus or Vulcan, Æsculapius, Nereus, Poscedon or Neptune, &c. Astarte, or Venus Urania, makes a conspicuous figure in the catalogue of Phœnician worthies; Pallas or Minerva is planted on the territory of Attica; in a word, all the branches of the family of the Titans, who in after ages figured in the rubric of the Greeks, are brought upon the stage, and their exploits and adventures briefly detailed.

By comparing this fragment with the mythology of the Atlantidæ and that of the Cretans preserved by Diodorus the Sicilian, lib. v. we think there is good reason to conclude, that the family of the Titans, the several branches of which seem to have been both the authors and objects of a great part of the Grecian idolatry, originally emigrated from Phœnicia.

As for the mythology of the Greeks and Romans, the illustrations of it which are given under various separate articles in this work are such as will, we conceive, render any more detailed account in this place entirely unnecessary.

MYTILUS. Mussel. In zoology, a genus of the class vermes, order testacea. Animal allied to an ascidia; shell bivalve, rough, generally affixed by a byssus or beard of silky filaments; hinge mostly without teeth, with generally a subulate, excavated, longitudinal line. Sixty-four species, scattered through the seas of the globe; eleven common to the coasts of our own country. They may be thus subdivided.

A. Parasitical: affixed as though by claws. Three species; of which the following is an example.

1. M. Crista galli. Shell plaited, spinous; both lips rough: offering four or five varieties. Inhabits the Indian ocean and Red sea, affixed to gorgonia; colour of the shell purple-violet, pale cinnamon or bay; rough, with raised dots; within, honey-colour; nearly equivalve, closed with five, eight, or ten oblique or straight acute plaits; hollow at the hinge, triangular.

B. Flat, or compressed into a flattened form, and slightly eared. Two species: of which the following is an example.

2. M. margaritiferus. Pearl mussel. Shell flattened, nearly orbicular, with a transverse base imbricate, with toothed tunics. Inhabits American and Indian seas; about eight inches long, and something broader: the inside is beautifully polished, and produces the true mother-of-pearl, and frequently most valuable pearls; the outside sometimes sea-green, or chesnut or bloom-colour with white rays, or whitish with green rays; when the outer coat is removed, it has the same perlaceous lustre as the inside: the younger shells have ears as long as the shells, and resemble scallops.

C. Ventricose or convex: including all the rest. The following are examples:

3. M. edulis. Edible mussel. Shell smoothish, violet, the valves slightly recurved on the obtuse side, and somewhat angular on the acute side: beaks pointed: shape nearly triangular; covered with a brownish skin; the colour below sometimes instead of violet, yellowish, or striped with pale rays. Inhabits the British coasts, European and Indian seas: generally from two to three inches long; but is much larger within the tropics, and smaller more northerly; found in large beds, and generally adhering to other bodies by means of a long silky beard: the fish affords a rich food, but is often extremely noxious to many constitutions.

4. M. anatinus. Duck mussel. Shell oval, a little compressed, very brittle, and semi-transparent, with a membranaceous margin; beaks decuticated. Inhabits the fresh waters of Great Britain, and of other parts of Europe: about five inches long and two and a quarter broad; the colour of the shell greenish with very fine striæ parallel with the aperture and a few blackish wrinkles; within glossy white, blue or yellowish, and sometimes shining with iridescent colours. Ducks and crows are extremely fond of this and M. cygneus, (a broader species found in rivers and ponds): and the crows, when the shell is too hard for their bills, fly with it to a great height, drop the shell on a rock, and pick out the meat after the shell is broken by the fall.

According to the observation of M. Mery, of the Paris academy, confirmed by observations of other naturalists, the mussel, in all its species, is androgynous: and that from a peculiar generative organization, each individual is of itself capable of propagating its species, and annually does so without any intercourse with any other individual; a mode of increase very different from what occurs in snails, earth-worms, and other androgynous or hermaphroditic animals. The mussel lays it eggs in the spring: these are minute, and are placed by the parent in due order in a very close arrangement, on the outside of theshell, where by means of a gluey matter they adhere very fast, and continually increase in size and strength, till becoming perfect mussels they fall off and shift for themselves, leaving the holes where they were placed, behind them: two or three thousand such holes are sometimes found on a single shell, which seems to prove an enormous fertility in this animal.

The mussel is infested by several enemies in its own element: one of the most cruel is a shell-fish of the irochus kind. This animal attaches itself to the shell of the mussel, pierces it with a round hole, and introduces a peculiar tube five or six inches long, which it turns in a spiral direction, and with which it sucks the substance of the mussel.

MYTTOTON, a coarse kind of food, used by the labouring people among the Greeks, and sometimes among the Romans. It was made of garlic, onions, eggs, cheese, oil, and vinegar, and reckoned very wholesome.

MYUS (anc. geog.), one of the twelve towns of Ionia; seated on the Meander, at the distance of 30 stadia from the sea. In Strabo's time it was incorporated with the Milesians, on account of the paucity of its inhabitants, from its being formerly overwhelmed with water; for which reason the Ionians consigned its suffrage and religious ceremonies to the people of Miletus. Artaxerxes allotted this town to Themistocles, in order to furnish his table with meat: Magnesia was to support him in bread, and Lamsacus in wine. The town now lies in ruins.

N.

N, A liquid consonant, or semivowel, and the thirteenth letter of the Greek, Latin, English, &c. alphabets.

The N is a nasal consonant: its sound is that of a d, passed through the nose: so that when the nose is stopped by a cold, or the like, it is usual to pronounce d for *n*. M. l'Abbe de Dangeau observes, that in the French the *n* is frequently a mere nasal vowel, without any thing of the sound of a consonant in it. He calls it the Sclavonic vowel. The Hebrews call their *N*, *Nun*, which signifies child, as being supposed the offspring of M; partly on account of the resemblance of sound, and partly on that of the figure. Thus from the m, by omitting the last column, is formed *n*: and thus from the capital *N*, by omitting the first column, is formed the Greek minuscule ν. Hence, for Biennius, &c. the Latins frequently use Bimus, &c. and the same people convert the Greek ν at the end of a word into an m; as, φαρμακον, *pharmacum*, &c. See M.

N before p, b, and m, the Latins change into m, and frequently into l and r, as in *ludo*, *illudo*; in *rigo*, *irrigo*, &c. in which they agree with the Hebrews, who, in lieu of Nun, frequently double the following consonant; and the Greeks do the same, as when for Manlius, they write Μαλλιος, &c.

The Greeks, also, before κ, γ, χ, ν, changed the ν into γ: in which they were followed by the ancient Romans, who for *Angulus* wrote *Aggulus*; for *anceps*, *agceps*, &c. The Latins retrench the *n* from Greek nouns ending in ων; as λεων, *leo*; δρακων, *draco*. On the contrary, the Greeks add it to the Latin ones ending in σ: as Κατων, Νερων, for *Cato*, *Nero*.

In English, N has an invariable sound: as *no*, *name*, &c. After *m* it is sometimes almost lost, as *condemn*, &c.

N, among the ancients, was a numeral letter, signifying 900; according to the verse in Baronius,

N quoque nongentos numero designat habendos.

And when a line was struck over it N̄, nine thousand.

Among the ancient lawyers, N. L. stood for *non liquet*, i. e. the cause is not clear enough to pass sentence upon.

N. P. was used among the Romans for *notarius publicus*; N. C. for Nero Cæsar, or Nero Claudius. N. B. is used for *nota bene*. In marine language, N stands for north.

N. or N°. in commerce, &c. is used as an abbrevation of *numero*, number. Thus also, in medicine, caryophyllorum, N°. vi. signifies six cloves. *N* on the French coins, denotes those struck at Montpelier.

NAAM, or NAM, NAMIUM, in law, the taking or distraining another man's moveable goods. This is either lawful, or unlawful and prohibited.

NAAM (Lawful), is a reasonable distress, proportionable to the value of the thing distrained for; and anciently called either *vif*, or *mort*, as it was made of quick, or dead chattel.

Lawful naam is so either by the common law, as when a man takes another's beasts doing damage in his ground; or by a man's particular fact, as on account of some contract, &c.

NAAM (Unlawful), *velitum namium*. See NAMIUM.

NAAS, a borough of Ireland, in the county of Kildare, at which the assizes are held alternately with Athy. It was formerly the residence of the kings of Leinster. It is 17 miles S.W. of Dublin, and 26 N.W. of Leinster. Lon. 6. 42 W. Lat. 53. 13. N.

To NAB. *v. a.* (*nappa*, Swed.) To catch unexpectedly.

NABAL, a town of the kingdom of Tunis, celebrated for its potteries. Near it are several remains of antiquity. It is seated near the sea, 32 miles S.S.E. of Tunis. Lon. 10. 19 E. Lat. 53. 13 N.

NABIS, a celebrated tyrant of Lacedæmon, who, in all acts of cruelty and oppression, surpassed a Phalaris or a Dionysius. When he had exercised every art in plundering the citizens of Sparta, he made a statue, which was like his wife, and whenever any one refused to deliver up his riches, the tyrant led him to the statue, which immediately, by means of springs, seized him in its arms, and tormented him in the most excruciating manner with bearded points hid under the clothes. Nabis made an alliance with the Romans, defeated Philopœmen in a naval engagement; he was, however, himself defeated, in his turn, and treacherously murdered as he attempted to save his life by flight, B. C. 192, after an usurpation of 14 years.

NABLOUS, a town of Turkey in Asia, and capital of a country which was the ancient kingdom of Samaria. It is the residence of a schiek, who farms the tribute to the pacha of Damascus. The soil of the country is fertile, and produces a great deal of corn, cotton, olives, and some silk. The inhabitants are such zealous Mahometans, that they will not suffer any Christians to remain among them. Nablous is 24 miles N. of Jerusalem, and 90 S.S.W. of Damascus. Lon. 35. 24 E. Lat. 32. 20 N.

NABLUM, in Hebrew, *nebel*, an instrument of music among the Hebrews. The

Seventy, and the Vulgate, translate it sometimes by nablum, and at other times by psalterion, or lyra, or even cithara.

The nablum was a stringed instrument, very near the form of a Δ, which was played upon by both hands, and with a kind of bow. See Calmet's Dissertation concerning the Instruments of Music of the ancient Hebrews, prefixed to the second volume of his commentary upon the Psalms.

NABO, or NEBO, in mythology, a deity of the Babylonians, who possessed the next rank to Bel. It is mentioned by Isaiah, ch. xlviii. Vossius apprehends that Nabo was the moon, and Bel the sun; but Grotius supposes that Nabo was some celebrated prophet of the country, which opinion is confirmed by the etymology of the name, signifying, according to Jerome, one that presides over prophesy.

NABOB, properly NAVAB, the plural of naib, a deputy: as used in Bengal it is the same as nazim.

NABONASSAR, first king of the Chaldæans or Babylonians; memorable for the Jewish æra which bears his name, which is generally fixed in 3257, beginning on Wednesday February 26th in the 3967th of the Julian period, 747 years before Christ. The Babylonians revolting from the Medes, who had overthrown the Assyrian monarchy, did, under Nabonassar, found a dominion, which was much increased under Nebuchadnezzar. It is probable that this Nabonassar is that Baladan in the second book of Kings xx. 12. father of Merodach, who sent ambassadors to Hezekiah. See 2 Chron. xxxii.

NACRE, in ichthyology. See PINNA.

NACRE. A term applied to that beautiful white enamel which forms the greater part of the substance of the oyter-shell, particularly the pearl oyster, and which is commonly known by the name of mother-of-pearl. For its properties and chemica composition, see CONCHOLOGY.

NADIR, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads. The zenith and nadir are the two poles of the horizon.

NAEFELS, a town of Switzerland, in the canton of Glaris. In 1388 a celebrated victory was gained near this place, by the inhabitants of this canton over the Austrians. Only about 350 troops of Glaris, assisted by fewer than 50 Schweitzers, withstood 15,000 Austrians, and, after a terrible slaughter, compelled them to retire; in memory of which glorious transaction, a chapel was built on the spot, which was rebuilt in 1779. The inhabitants are Roman catholics. It is four miles N. of Glaris.

NAERDEN, a strong town of Holland, at the head of the canals of the province. It has experienced many calamities; particularly in 1572, when it was taken by Fernando de Toledo, son of the duke of Alva, and all the inhabitants, without distinction of age or sex, were massacred. It is seated on the Zuider-Zee, 14 miles E. of Amsterdam, and 15 N. of Utrecht. Lon. 5. 9 E. Lat. 52. 20 N.

NÆVI MATERNI. (*nævus*, Hebrew.) Metroceles. Mother's marks. These marks are upon the skin of children at birth, and are various in their nature, often depending upon the longing or aversion of the mother; hence they resemble mulberries, grapes, bacon, &c. Their seat is mostly in the rete mucosum or cellular membrane.

CN. NÆVIUS. The most remarkable of this name is an augur in the reign of Tarquin, who, in order to convince the king and the Romans of his power as an augur, cut a flint with a razor, and turned the ridicule of the populace into admiration. Tarquin rewarded his merit by erecting him a statue in the comitium, which was still in being in the age of Augustus. The razor and flint were buried near it under an altar, and it was usual among the Romans to make witnesses, in civil causes, swear near it. This event is treated as fabulous and improbable by Cicero.

NÆVIUS (Cneius), a Latin poet, who served originally in the army, but quitted that profession, and devoted himself to letters. He wrote several comedies, one of which was so displeasing to Metellus, the consul, on account of its satirical strokes, that he got him banished to Utica, where he died 203 B.C. Some fragments of his are extant.

NÆVUS. See NÆVI.

NAG. *s.* (*nagge*, Dutch.) A small horse; or familiarly any horse used for riding.

NAGOLD, a town of Suabia, in the duchy of Wirtemburg, with a strong castle, situate on a river of the same name, 10 miles W. of Tubingen. Lon. 8. 37 E. Lat. 48. 30 N.

NAGORE, a town of Hindustan Proper, in the country of Agimere, 40 miles N. W. of Agimere. Lon. 74. 10 E. Lat. 27. 8 N.

NAGPOUR, a city of the Deccan of Hindustan, capital of that part of Berar which is subject to a chief of the Eastern Mahrattas. It is extensive and populous, but meanly built; and, excepting a small citadel, is open and defenceless. It is 560 miles W. by S. of Calcutta. Lon. 79. 46 E. Lat. 21. 8 N.

NAGYBANJA, a town of Hungary, which is a metal town, and one of the royal free towns. The gold and silver mine-works are of great produce, and the money coined here is distinguished by the mark NB. It is 30 miles N.E. Zatmar. Lon. 22. 54 E. Lat. 48. 10 N.

NAHE, a river of the palatinate of the Rhine, which flows by Birkenfeld, Oberstein, Kreuzenach, and Bingen, and falls into the Rhine.

NAHUM, or the Prophecy of Nahum, a canonical book of the old Testament.

Nahum, the seventh of the 12 lesser prophets, was a native of Elkoshai, a little village of Galilee. The subject of his prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner; his style is bold and figurative, and cannot be exceeded by the most perfect masters of oratory. This prophecy was verified at the siege of that city by Astyages, in the year of the world 3378, 626 years before Christ.

NAIADES, certain inferior deities who presided over rivers, springs, wells, and fountains. They generally inhabited the country, and resorted to the woods or meadows near the stream over which they presided, whence the name (ναειν, *to flow*). Ægle was the fairest of the Naiades, according to Virgil.

NAJAS. In botany, a genus of the class dioecia, order monandria. Male: calyx cylindrical, cloven; corol four-cleft, filamentless. Female: calyxless; corolless; pistil one; capsule ovate, one-celled. One species, common to the sea-coasts of Europe; stem with triangular spines; leaves narrow, with spinous teeth on each side; flowers axillary, solitary.

NAIL. *s.* (nægl, Saxon; *nagel*, German.) 1. The horny substance at the ends of the fingers and toes (*Dryden*). 2. The talons of birds; the claws of beasts. 3. A spike of metal by which things are fastened together (*Watts*). 4. A stud; a boss (*Swift*). 5. A measure of length; two inches and a quarter. 6. *On the nail.* Readily; immediately; without delay (*Swift*).

To NAIL. *v. a.* 1. To fasten with nails (*Milton*). 2. To stud with nails (*Dryden*). Of these see more, as below.

NAILS. *Ungues.* In anatomy, horny laminæ, situated on the extremities of the fingers and toes.

NAILS of the bridle hand, in the manage. The different position or situation of the nails of the bridle or left hand of a horseman enables the horse with facility to change hands, and form his departure and stop; since the motion of the bridle follows such a position of the nails. To give a horse head, turn the nails downwards. To turn the horse to the right, turn them upwards, moving the hand to the right. To change to the left, turn the nails down, and bear to the left. To stop the horse, lift up or raise the hand.

NAILS (Horse.) See SHOEING.

NAILS, in building, &c. small spikes of iron, brass, &c. which being driven into wood, serve to bind several pieces together, or to fasten something upon them. The several sorts of nails are very numerous: as 1. Back and bottom nails; which are made with flat shanks to hold fast, and not open the wood. 2. Clamp-nails, for fastening the clamps in buildings, &c. 3. Clasp-nails, whose heads clasping and sticking into the wood, render the work smooth, so as to admit a plane over it. 4. Clench-nails, used by boat and barge builders, and proper for any boarded buildings that are to be taken down, because they will drive without splitting the wood, and draw without breaking; of these there are many sorts. 5. Clout-nails, used for nailing on clouts to axle-trees. 6. Deck-nails, for fastening of decks in ships, doubling of shipping, and floors laid with planks. 7. Dog-nails, for fastening hinges on doors, &c. 8. Flat-points, much used in shipping, and are proper where there is occasion to draw and hold fast, and no conveniency of clenching. 9. Jobent-nails, for nailing thin plates of iron to wood, as small hinges on cupboard-doors, &c. 10. Lead-nails, for nailing lead, leather, and canvass, to hard wood. 11. Port-nails, for nailing hinges to the ports of ships. 12. Pound-nails, which are four-square, and are much used in Essex, Norfolk, and Suffolk, and scarcely any where else, except for pailing. 13. Ribbing-nails, principally used in ship-building, for fastening the ribs of ships in their places. 14. Rose-nails, which are drawn four-square in the shank, and commonly in a round tool, as all common two-penny nails are; in some countries all the larger sort of nails are made of this shape. 15. Rother-nails, which have a full head, and are chiefly used in fastening rother-irons to ships. 16. Round-head nails, for fastening on hinges, or for any other use where a neat head is required; these are of several sorts. 17. Scupper nails, which have a broad head, and are used for fastening leather and canvass to wood. 18. Sharp-nails; these have sharp points and flat shanks, and are much used, especially in the West-Indies, for nailing soft wood. 19. Sheathing-nails, for fastening sheathing-boards to ships. 20. Square-nails, which are used for hard wood, and nailing up wall-fruit. 21. Tacks, the smallest of which serve to fasten paper to wood; the middling for wool-cards, &c. and the larger for upholsterers and pumps. Nails are said to be toughened when too brittle, by heating them in a fire-shovel, and putting some tallow or grease among them.

NAILER, is used sometimes to denote one who nails, at others a nail-maker.

NAILING of cannon, more commonly called spiking. When circumstances make it necessary to abandon cannon, or when the enemy's artillery are seized, and it is not however possible to take them away, it is proper to nail them up, in order to render them useless; which is done by driving a large nail or iron spike into the vent of a piece of artillery, to render it unserviceable. There are various contrivances to force the nail out, as also sundry machines, invented for that purpose, but they have never been found of general use; so that the best method is to drill a new vent. One Gasper Vimercalus was the first who invented the nailing of cannon. He was a native of Bremen, and made use of his invention first in nailing up the artillery of Sigismund Malatesta.

NAIRN, a borough of Scotland, the county-town of Nairnshire, with a small harbour. It is seated at the mouth of the Nairn, on the Murray Frith, 15 miles N.E. of Inverness, and 120 N. of Edinburgh. Lon. 3. 6 W. Lat. 57. 38 N.

NAIRNSHIRE, a county of Scotland, 15 miles long and 10 broad; bounded on the N. by the Murray Frith, and inclosed on every other side by the counties of Inverness and Murray. It is divided into four parishes, and sends one member to parliament alternately with Cromarty. The number of inhabitants in 1801 was 8257. The S. part is mountainous, but toward the N. it is level, and the soil abundantly fertile.

NAIS, in zoology, a genus of the class vermes, order mollusca. Body creeping, long, linear, pellucid, depressed; peduncles or feet with small bristles on each side; feelerless; eyeless, or with two. Ten species; three of them common to the stagnant waters or sandy sediments of our own country; the rest for the most part found on the shores of the North Seas; generally only a few lines long, and attached to the stalks of aquatic plants. The largest, which is the quadricuspidata, is two inches and a half long, and inhabits the sandy coast of Iceland under stones, with bifid, bristly, lateral warts, and a four-cleft tail; the body composed of a hundred and four annular segments, sometimes pale red, sometimes reddish grey, with a longitudinal purplish line, of a richer colour beneath. See Nat. Hist. Pl. CXLIX.

NAIS, one of the Oceanides, mother of Chiron or Glaucus, by Magnes. 2. A nymph in an island of the Red sea, who, by her incantations, turned to fishes all those who approached her residence after she had admitted them to her embraces. She was herself changed into a fish by Apollo.

NAISSANT, in heraldry, is applied to any animal issuing out of the midst of some ordinary, and showing only his head, shoulders, fore-feet, and legs, with the tip of his tail, the rest of his body being hid in the shield, or some charge upon it; in which it differs from issuant, which denotes a living creature arising out of the bottom of any ordinary or charge.

NA'KED. *a.* (nacoð, Saxon.) 1. Wanting clothes; uncovered; bare (*Milton*). 2. Unarmed; defenceless; unprovided (*Addison*). 3. Plain; evident; not hidden (*Shakspeare*). 4. Mere; bare; simple; abstracted (*Hooker*).

NAKED. *Nudus.* In botany. When applied to the stem or trunk of a vegetable, it signifies, that it is without leaves, fulcres or arms. *Qui foliis, fulcris et armis caret.* Delin. Pl. In Philos. Botan. it is said only to be destitute of leaves, but that is expressed by the term aphyllus, leafless. When applied to the leaf, it signifies, that it is destitute of all pubescence. *Setis ac pilis destitutum.* Delin. Pl. and is opposed to *tectum*, covered, in Philos. Bot. p. 233.—When applied to the flower, it implies, that the calyx is wanting; but it would be more properly called a naked flower if the corol were wanting as well as the calyx; however, it rarely happens that a flower is destitute of both. Philos. Bot. p. 76. When applied to the receptacle, it means, that it is without hairs, bristles or chaffs. When applied to a head of flowers (*capitulum*), it is opposed to leafy (*foliosum*), and implies that it has no leaves on it. When applied to a whorl (*verticillus*), the meaning is, that there is no involucre. In the same sense it is applied to the raceme, petiole, peduncle, &c.

NA'KEDLY. *ad.* 1. Without covering. 2. Simply; merely (*Holder*). 3. Discoverably; evidently (*Daniel*).

NA'KEDNESS. *s.* (from *naked.*) 1. Nudity; want of covering (*Milton*). 2. Want of provision for defence (*Genesis*). 3. Plainness; evidence; want of concealment (*Shaksp.*).

NAKOUS, an Egyptian musical instrument, made like two plates of brass, and of all sizes, from two inches to a foot in diameter; they hold them by strings fastened to their middles, and strike them together so as to beat time. They are used in the Coptic churches, and in the Mahometan processions.

NAKSIVAN, a town of Persian Armenia, capital of a province of the same name. It was formerly a large city, but ruined by Abbas I. who removed the inhabitants into the interior parts of Persia. Here are now some considerable bazars, caravanseras, public baths, and other buildings. It is 90 miles S.E. of Erivan, and 250 E. of Erzerum. Lon. 45. 30 E. Lat. 38. 40 N.

NALL. See AWL.

NAMA, in botany, a genus of the class pentandria, order digynia. Calyx five-leaved; corol five-parted; capsule one-celled, two-valved. One species, a native of Jamaica; herbaceous, with axillary flowers, two or four together.

NAME. *s.* (nama, Saxon; *naem*, Dutch.) 1. The discriminative appellation of an individual (*Shakspeare*). 2. The term by which any kind or species is distinguished (*Locke*). 3. Person (*Dryden*). 4. Reputation; character (*Clarendon*). 5. Renown; fame; celebrity (*Bacon*). 6. Power delegated; imputed character (*Shakspeare*). 7. Fictitious imputation (*Dryden*). 8. Appearance; not reality; assumed character (*Shakspeare*). 9. An opprobrious appellation (*Granville*).

NAMES are distinguished into proper and appellative.

Proper names, are those which represent some individual thing or person, so as to distinguish it from all other things of the same species; as, Socrates, which represents a certain philosopher.

Appellative or *general names*, are those which signify common ideas; or which are common to several individuals of the same species; as, horse, animal, man, oak, &c.

Proper names are either called christian, as being given at baptism; or surnames: the first imposed for distinction of persons, answering to the Roman *prænomen*; the second, for the distinction of families, answering to the *nomen* of the Romans, and the *patronymicum* of the Greeks. See SURNAME.

Originally every person had but one name; as among the Jews, Adam, &c.; among the Egyptians, Busiris; among the Chaldees, Ninus; the Medes, Astyages; the Greeks, Diomedes; the Romans, Romulus; the Gauls, Diuitacus; the Germans, Ariovistus; the Britons, Cassibelan; the English, Hengist, &c. And thus of other nations, except the savages of Mount Atlas, whom Pliny and Marcellinus represent as *anonyme*, nameless.

The Jews gave the name at the circumcision, viz. eight days after the birth; the Romans, to females the same day, to males the ninth; at which time they held a feast, called *nominalia.*

Since christianity has obtained, most nations have followed the Jews, giving the name on the eighth day after the birth; except our English ancestors, who, till of late, baptized and gave the name on the birth-day.

It is an observation deserving attention, says the Abbe Barthelemi, that the greater part of names found in Homer are marks of distinction. They are given in honour of the qualities most esteemed in the heroic ages. From the word *polemos*, which signifies war, have been formed Thepolemus and Archeptolemus, the names of two heroes mentioned in the Iliad. The former name signifies able to support, and the latter, able to direct, the labours of war. By adding to the word *mache*, or battle, certain prepositions and different parts of speech, which modify the sense in a manner always honourable, are composed the names Amphimachus, Antimachus, Promachus, Telemachus. Proceeding in the same way with the word *honorea*, strength or intrepidity, they formed the names Agapenor, he who esteems valour; Agenor, he who directs it. From *thoes*, swift, are derived, Alcathoes, Panthoes, Perithoes, &c. From *nous*, mind or intelligence, come Astynoes, Arsinoes, Autenoes, &c. From *medes*, counsel, Agamedes, Eumedes, Lycomedes, Thrasymedes, and so on.

Of late years it has obtained among us to give surnames for christian names; which some dislike, on account of the confusion it may introduce. Camden relates it as an opinion, that the practice first began in the reign of Edward VI. by such as would be god-fathers, when they were more than half fathers. Upon which some were persuaded to change their names at confirmation; which, it seems, is usual in other countries. Thus, two sons of Henry II. of France, christened Alexander and Hercules, changed them at confirmation into Henry and Francis. In monasteries the religious assume new names at their admittance, to show they are about to lead a new life, and have renounced the world, their family, and even their name; v. g. sister Mary of the Incarnation, brother Henry of the Holy Sacrament, &c. The popes also changed their names at their exaltation to the pontificate; a custom first introduced by pope Sergius, whose name till then, as Platina informs us, was Swine-snout. But Onuphrius refers it to John XII. or XIII. and at the same time adds a different reason for it from that of Platina, viz. that it was done in imitation of St. Peter and St. Paul, who were first called Simon and Saul.

Among the ancients, those deified by the heathen consecrations had new names given them; Romulus was called Quirinus; Melicertes, Portunus, or Portumnus, &c.

New names were also given in adoptions, sometimes by testament; thus L. Æmilus, adopted by Scipio, took the name of Scipio Africanus; and thus Augustus, who at first was called C. Octavius Thurinus, being adopted by the testament of Julius Cæsar into his name and family, took the name of Caius Julius Cæsar Octavianus.

To NAME. *v. a.* 1. To discriminate by a particular appellation imposed (*Shakspeare*). 2. To mention by name (*Ecclus*). 3. To specify; to nominate (*Locke*). 4. To utter; to mention (*Genesis*).

NA'MELESS. *a.* (from *name.*) 1. Not distinguished by any discriminative appellation (*Denham*). 2. One of which the name is not known or mentioned (*Atterbury*).

NA'MELY. *ad.* (from *name.*) Particularly; specially; to mention by name (*Addison*).

NA'MER. *s.* (from *name*). One who calls or knows any by name.

NA'MESAKE. *s.* One that has the same name with another.

NAMPTWICH. See NANTWICH.

NAMUR, a county, and one of the ten catholic provinces, of the Netherlands, 30 miles long and 20 broad; bounded on the N. by Brabant, and on all the other sides by the territory of Liege and a small part of Hainault. It is pretty fertile; has several forests, marble quarries, and mines of iron, lead and coal. The rivers Meuse and Sambre divide it into three parts, nearly of equal extent. By the new division of the French it forms the chief part of the department of Sambre and Meuse.

NAMUR, a city of the Netherlands, capital of the county of Namur, or the department of Sambre and Meuse, and a bishop's see. It has a castle in the middle of the town, on a craggy rock, and several forts. The inhabitants are estimated at 20,000. Fire-arms, swords, knives, and many other kinds of cutlery are made here. This city was ceded to the house of Austria by the peace of Utrecht. In 1715 it was allowed to be garrisoned by Dutch troops, as one of the barrier towns of the United Provinces; in 1746 it was taken by the French, but restored in 1748. In 1781 emperor Joseph expelled the Dutch garrison. In 1792 it was again taken by the French, who were compelled to evacuate it the following year, but they regained possession of it in 1794. It is seated between two mountains, at the confluence of the Maese and Sambre, 24 miles W.S.W. of Liege, and 32 S.E. of Brussels. Lon. 4. 45 E. Lat. 50. 29 N.

NANCI, or NANCY, a city of France, capital of the department of Meurte, and a bishop's see. It is divided by a canal into the old and new town. The first, though irregularly built, is rich and populous, and contains the palace of the ancient dukes of Lorrain; and their tombs are in a rich saloon, which adjoins the church of the late Cordeliers. The new town, whose streets are perfectly straight, was already one of the finest in Europe, before the magnificent works with which Stanislaus I. titular king of Poland, and duke of Lorrain, enriched it. The cathedral is a superb structure. Nancy is seated in a delightful plain, near the river Meurte, 92 miles N. W. of Basel, and 175 E. of Paris. Lon. 6. 10 E. Lat. 48. 42 N.

NANDIDROOG, a strong fortress of Hindustan, in Mysore. Since the restoration of the rajah, in 1799, it has been garrisoned by English troops. It is 25 miles N. by E. of Bangalore, and 64 E.S.E. of Sera.

NANDINA, in botany, a genus of the class hexandria, order monogynia. Calyx inferior, many-leaved, imbricate; corol six-petalled; berry juiceless, two-seeded. One species; a branched shrub of Japan, with more than decompound leaves, and terminal panicle.

NANFIO, an island of the Archipelago, a little to the E. of that of Santorini. It is 16 miles in circumference, but has no harbour, nor springs sufficient to water the fields. The inhabitants are all Greeks, and their trade is in onions, wax, and honey. The ruins of the temple of Apollo are yet to be seen, and consist chiefly of marble columns. Lon. 26. 10 E. Lat. 36. 15 N.

NANI (John Baptist), a Venetian, proctor of St. Mark. He was admitted into the college of senators, 1641, and went as ambassador to France, and obtained from the French court succours in men and money to continue the war against the Turks in Candia. He was afterwards ambassador to the emperor, and was appointed, for his services, proctor of St. Mark, and captain general of the marine. He died in 1678. He was the author of an history of Venice, undertaken at the request of the senate, 2 vols. 4to.

NANKEEN, or NAN-KING, is a well-known cotton stuff, which derives its name from the ancient capital of China. It is, however, according to Van Braam, manufactured at a great distance from that city, in the district of Fong-kiang-fou, situated in the south-east of the province of Kiang-nam upon the sea-shore. The colour of nankeen is natural, the down of which it is made being of the same yellow tinge with the cloth. The colour, as well as superior quality of this cotton, seems to be derived from the soil; for it is said that the seeds of the nankeen cotton degenerate in both particulars when transplanted to another province, however little different in its climate. The common opinion, that the colour of the stuff is given by a dye, occasioned an order from Europe, some years ago, to dye the pieces of nankeen of a deeper colour than they had at that period; and the reason of their being then paler than formerly is as follows:

Shortly after the Americans began to trade with China, the demand increased to nearly double the quantity it was possible to furnish. To supply this deficiency, the manufacturers mixed common white cotton with the brown; this gave it a pale cast, which was immediately remarked; and for this lighter kind no purchaser could be found till the other was exhausted. As the consumption is grown less during the last three years, the mixture of cotton is no longer necessary, and nankeen is became what it was before. By keeping them two or three years, it even appears that they have the property of growing darker. This kind of stuff must be acknowledged to be the strongest yet known. Many persons have found that clothes made of it will last three or four years, although for ever in the wash. This it is that makes them the favourite wear for breeches and waistcoats both in Europe and America. The white nankeen is of the same quality, and is made of white cotton as good as the brown, and which also grows in Kiang-nam.

NAN-KING, or KIANG-NIN, a city of China, capital of the province of Kiang-nan, said to have been formerly one of the most beautiful and flourishing cities in the world. When the Chinese speak of its extent, they say, if two horsemen should go out in the morning by the same gate, and ride round it on full speed, taking different directions, they would not meet before night. This account is evidently exaggerated; but it is certain, that Nan-king surpasses in extent all the other cities of China. We are assured, that its walls are five leagues and a half in circumference. This city is situated at the distance of a league from the river Yang-tse-kiang; it is of an irregular figure; the mountains which are within its circumference having prevented its being built on a regular plan. It was formerly the imperial city; for this reason it was called Nan-king, which signifies, the southern court; but since the six grand tribunals have been transferred from hence to Pe-king, it is called Kiang-ning in all the public acts. Nan-king has lost much of its ancient splendour: it had formerly a magnificent palace, no vestige of which is now to be seen; an observatory, at present neglected; temples, tombs of the emperors, and other superb monuments, of which nothing remains but the remembrance. A third of the city is deserted, but the rest is well inhabited. Some quarters of it are extremely populous and full of business. The streets are not so broad as those of Pe-king; they are, however, very beautiful, well paved, and bordered with rich shops. Here are no public edifices corresponding to the reputation of so celebrated a city, excepting its gates, which are very beautiful, and some temples, among which is the famous porcelain tower. It is two hundred feet high, and divided into nine stories, by plain boards within and without, by cornices and small projections covered with green-varnished tiles. There is an ascent of forty steps to the first story; between each of the others there are twenty-one: 500 miles S.S.E. Pe-king. Lon. 118. 47 E. Lat. 32. 5 N.

NANTES, an ancient and flourishing commercial town of France, in the department of Lower Loire, with a bishop's see, and a university. It was formerly the residence of the dukes of Bretagne, who built a strong castle on the side of the river, which still exists. The cathedral contains the tombs of the ancient dukes. The bridges over the Loire, in which are some islands, are almost a league in length. The suburbs exceed the city in extent. The inhabitants are computed at 60,000. Since the peace in 1783, Nantes has had a considerable share in the commerce with the United

States. A great quantity of salt is made in the territory of Nantes, both at the bay of Bourgneuf, and in the salt marshes of Guerande and Croisic. Large vessels can come no higher than Port Launai, which is 12 miles from Nantes. It was here that Henry IV. promulgated the famous edict, in 1598, in favour of the protestants, which was revoked in 1685 by Lewis XIV. Nantes is 58 miles S. by E. of Rennes, and 217 S.W. of Paris. Lon. 1. 45 W. Lat. 47. 13 N.

NANTUCKET, an island in the state of Massachusets, of which it is a county. It lies to the S. of Cape Cod, and had once the most considerable whale fishery on the coast; but it was almost ruined by the civil war. As the island is low, sandy, and barren, the inhabitants depend almost entirely on the watery element for subsistence. It has but one town, called Sherburne, which is 83 miles S. of Boston. Lon. 70. 30 W. Lat. 41. 0 N.

NANTUEIL (Robert), a celebrated miniature painter and engraver, was born at Rheims in 1630. He drew the portrait of Louis XIV. in crayons with so much elegance, that the king made him designer and engraver to his cabinet, with a considerable salary. He died at Paris in 1678. His engravings of portraits are highly valued.

NANTWICH, or NAMPTWICH, a town of England, in the county of Chester, situated on the river Weaver, which divides it in two parts, and by the Chester canal, which is finished here with a broad bason, forming a kind of harbour. The inhabitants carry on a considerable trade in salt and cheese; for both of which this town and environs are celebrated. A cotton manufacture has lately been established; that of shoes has been of some continuance. The town is governed by a constable, &c. who are guardians of the salt springs. Here is a large weekly market for corn and cattle, held on Saturday: nineteen miles and a half S.E. Chester, and 162 N.W. London.

NAP. *s.* (hnœppan, Saxon, to sleep.) 1. Slumber; a short sleep (*Sidney*). 2. (hnoppa, Saxon.) Down; villous substance (*Spenser*).

To NAP. *v. a.* (hnœppan, Saxon.) To sleep; to be drowsy or secure (*Hudibras*).

NAPÆA, in botany, a genus of the class dioecia, order monadelphia. Calyx five-cleft; petals five. Male: stamens numerous; styles numerous, barren. Female: stamens numerous, barren; styles numerous, longer than the stamens; capsule depressed, ten-celled; seeds solitary. Two species, natives of Virginia; and both hardy, herbaceous, flowering perennials, frequently found in the borders of our pleasure-gardens.

NAPÆA, certain divinities among the ancients, who presided over the hills and woods of the country. Some suppose that they were titulary deities of the fountains and the Naiades of the sea. Their name is derived from ναπη, a grove.

NAPAUL, a province of Hindustan Proper, bounded on the S. by Bahar, on the W. by Oude and Rohilcund, on the N.W. by Sirinagur, and on the N.E. and E. by the ridge of mountains called Himmaleh, by which it is separated from Thibet. Catmandu is the capital.

NAPELLUS. (*napellus*, dim. of *napus*, a kind of turnip, because it has a bulbous root like a turnip.) Wolf's bane. See ACONITUM.

NAPE. *s.* The joint of the neck behind (*Shakspeare*).

NA'PERY. *s.* (*naperia*, Italian.) Table linen.

NAPHÆ FLORES. A term sometimes applied to the flowers of the citrus aurantium. See AURANTIUM.

NAPHTHA, in mineralogy, a species of BITUMEN; which see.

NAPIER (John), baron of Merchiston, inventor of the logarithms, was the eldest son of sir Archibald Napier of Merchiston, and born in the year 1550. Having given early discoveries of great natural parts, his father was careful to have them cultivated by a liberal education. After going through the ordinary courses of philosophy at the university of St. Andrew's, he made the tour of France, Italy, and Germany. Upon his return to his native country his literature and other fine accomplishments soon rendered him conspicuous, and might have raised him to the highest offices in the state; but declining all civil employments, and the bustle of the court, he retired from the world to pursue literary researches, in which he made an uncommon progress, so as to have favoured mankind with sundry useful discoveries. He applied himself chiefly to the study of mathematics; but at the same time did not neglect that of the Holy Scriptures. In both these he has discovered the most extensive knowledge and profound penetration. His essay upon the book of the Apocalypse indicates the most acute investigation, and an uncommon strength of judgment; though time has discovered, that his calculations concerning particular events had proceeded upon fallacious data. But what has chifly rendered his name famous, was his great and fortunate discovery of logarithms in trigonometry, by which the ease and expedition in calculation have so wonderfully assisted the science of astronomy and the arts of practical geometry and navigation. Napier, having a great attachment to astronomy, and spherical trigonometry, had occasion to make many numeral calculations of such triangles, with sines, tangents, &c.; and these being expressed in large numbers, they hence occasioned a great deal of labour and trouble: to spare themselves part of this labour, Napier, and other authors about his time, set themselves to find out certain short modes of calculation, as is evident from many of their writings. To this necessity, and these endeavours it is, that we owe several ingenious contrivances; particularly the computation by Napier's rods, and several other curious and short methods that are given in his Rabdologia; and at length, after trials of many other means, the most complete one of logarithms, in the actual construction of a large table of numbers in arithmetical progression, adapted to a set of as many others in geometrical progression. The property of such numbers had been long known; viz. that the addition of the former answered to the multiplication of the latter, &c.; but it wanted the necessity of such very troublesome calculations as those above mentioned, joined to an ardent disposition, to make such a use of that property. Perhaps also this disposition was urged into action by certain attempts of this kind, which it seems were made elsewhere. Whatever might be the inducement however, Napier published his invention in 1614, under the title of Logarithmorum Canonis Descriptio, &c., containing the construction and canon of his logarithms, which are those of the kind that is called hyperbolic. This work coming presently to the hands of Mr. Briggs, then professor of geometry at Gresham College in London, he immediately gave it the greatest encouragement, teaching the nature of the logarithms in his public lectures, and at the same time recommending a change in the scale of them, by which they might be advantageously altered to the kind which he afterwards computed himself, which are thence called Briggs's Logarithms, and are those now in common use. Mr. Briggs also presently wrote to lord Napier upon this proposed change, and made journeys to Scotland the two following years to visit Napier, and consult him about that alteration, before he set about making it. Briggs, in a letter to archbishop Usher, March 10, 1615, writes thus: "Napier lord of Markinston hath set my head and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder." Briggs accordingly made him the visit, and staid a month with him.

The following passage, from the life of Lilly the astrologer, contains a curious account of the meeting of those two illustrious men. "I will acquaint you (says Lilly) with one memorable story related unto me by John Marr, an excellent mathematician and geometrician, whom I conceive you remember. He was servant to king James and Charles the First. At first when the lord Napier, or Marchiston, made public his logarithms, Mr. Briggs, then reader of the astronomy lectures at Gresham College in London, was so surprised with admiration of them, that he could have no quietness in himself until he had seen that noble person the lord Marchiston, whose only invention they were: he acquaints John Marr herewith, who went into Scotland before Mr. Briggs, purposely to be there when these two so learned persons should meet. Mr. Briggs appoints a day when to meet at Edinburgh; but failing thereof, the lord Napier was doubtful he would not come. It happened one day as John Marr and the lord Napier were speaking of Mr. Briggs; 'Ah, John, (said Marchiston), Mr. Briggs will not now come.' At the very instant one knocks at the gate; John Marr hasted down, and it proved Mr. Briggs to his great contentment. He brings Mr. Briggs up into my lord's chamber, where almost one quarter of an hour was spent, each beholding other almost with admiration before one word was spoke. At last Mr. Briggs began: 'My lord, I have undertaken this long journey purposely to see your person, and to know by what engine of wit or ingenuity you came first to think of this most excellent help into astronomy, viz. the logarithms; but, my lord, being by you found out, I wonder nobody else found it out before, when now known it is so easy.' He was nobly entertained by the lord Napier; and every summer after that, during the lord's being alive, this venerable man, Mr. Briggs, went purposely into Scotland to visit him."

Napier made also considerable improvements in spherical trigonometry, &c. particularly by his Catholic or Universal Rule, being a general theorem by which he resolves all the cases of right-angled spherical triangles in a manner very simple and easy to be remembered, namely, by what he calls the Five Circular Parts. His construction of logarithms too, beside the labour of them, manifests the greatest ingenuity. Kepler dedicated his Ephemerides to Napier, which were published in the year 1617; and it appears from many passages in his letter about this time, that he accounted Napier to be the greatest man of his age in the particular department to which he applied his abilities.

The last literary exertion of this eminent person was the publication of his Rabdology and Promptuary, in the year 1617; soon after which he died at Marchiston, the 3d of April in the same year, in the 68th year of his age.—The list of his works is as follows:

1. A Plain Discovery of the Revelation of St. John; 1593.

2. Logarithmorum Canonis Descriptio; 1614.

3. Mirifici Logarithmorum Canonis Constructio; et eorum ad Naturales ipsorum numeros habitudines; una cum appendice, de alia eaque præstantiore Logarithmorum specie condenda. Quibus accessere propositiones ad triangula sphærica faciliore calculo resolvenda. Una cum Annotationibus aliquot doctissimi D. Henrici Briggii in eas, et memoratum appendicem. Published by the author's son in 1619.

4. Rabdologia, seu Numerationis per Virgulas, libri duo; 1617. This contains the description and use of the bones or rods; with several other short and ingenious modes of calculation.

5. His Letter to Anthony Bacon (the original of which is in the archbishop's library at Lambeth), entitled, Secret Inventions, Profitable and Necessary in these Days for the Defence of this Island, and withstanding Strangers Enemies to God's Truth and Religion; dated June 2, 1596.

Napier's bones, or rods, an instrument contrived by lord Napier, for the more easy performing of the arithmetical operations of multiplication, division, &c. These rods are five in number, made of bone, ivory, horn, wood, or pasteboard, &c. Their faces are divided into nine little squares; each of which is parted into two triangles by diagonals. In these little squares are written the numbers of the multiplication-table; in such manner as that the units, or right-hand figures, are found in the right-hand triangle; and the tens, or the left-hand figures, in the left-hand triangle. The method of using them need not be here explained.

NA'PKIN, *s.* (from *nap.*) 1. A cloth used at table to wipe the hands. 2. A handkerchief: obsolete (*Shakspeare*).

NAPLES, once a celebrated kingdom of Europe, comprehending the S. part of Italy, bounded on the N.W. by the ecclesiastical state, N.E. by the gulf of Venice, and every where else by the Mediterranean. It is 300 miles in length, by 100 in breadth, and divided into twelve provinces; namely, Terra di Lavoro (the ancient Campania Felix), Principato Citeriore and Ulteriore, Molise, Basilicata, Calabria Citeriore and Ulteriore, Abruzzo Citeriore and Ulteriore, Capitanata, Terra di Bari, and Terra d'Otranto; the last three forming the ancient Apulia, now called Puglia, on the E. side of the kingdom. After many revolutions, the Normans became masters of this country in the eleventh century; and the sovereigns were called counts, then dukes, and afterwards kings of Puglia. In 1282, Peter III., king of Arragon, caused all the Normans in the island of Sicily to be massacred; and this massacre was called the Sicilian Vespers. After this Puglia was joined to Sicily; and hence the sovereigns took the title of king of the Two Sicilies. It has also been called the kingdom of Naples, from its capital. France and Spain contended for the sovereignty in the sequel, and bloody wars and revolutions were the consequence. The French being defeated by the Spaniards in 1504, Lewis XII. formally renounced all pretensions to the crown, and the country was governed by Spanish viceroys. In 1647 happened the dreadful insurrection of Massaniello in the city of Naples, by which the Spaniards were nearly expelled. The people, however, returning to their allegiance, on the assassination of Massaniello, the Spaniards continued in peaceable possession of the kingdom till 1707, when it was conquered by prince Eugene, and ceded to the emperor by the treaty of Rastadt in 1714. It was recovered, however, by the Spaniards in 1734; and Ferdinand IV., a prince of Spain, is now king of Naples and Sicily. The title of the king's eldest son is prince of Calabria. The climate is extremely hot, especially in July, August, and September; and is said to be one of the most inconstant and unfavourable to valetudinarians. In some seasons it rains every day for six or seven weeks together; but the most disagreeable part of the climate is the siroco, or S.E. wind, which is very common in May, and extremely relaxing. In winter there is seldom any ice or snow, except on the mountains. The country abounds with grain, the finest fruits and vegetables, rice, flax, oil, wine, saffron, and manna; and affords alum, vitriol, sulphur, rock crystal, marble, minerals, and fine wool and silk. Beside the manufactures noticed in the account of the city of Naples, waistcoats, caps, stockings, and gloves are also made of the hair or filaments of a shell-fish, which are warmer than those of wool, and of a beautiful glossy green. The principal mountains are the Apennines, which traverse this country from N. to S., branching out to the two extremities; and the celebrated volcano, mount Vesuvius. The rivers are numerous, but inconsiderable; the chief are the Garigliano and Volturno. One of the greatest inconveniences to which this kingdom is exposed is earthquakes. The established religion is the Roman catholic, and the clergy and convents possess two-thirds of the whole kingdom; but protestants and Jews are allowed to settle here.

Such was the former state of Naples. But being seized by the emperor of France, he affirmed "the Neapolitan dynasty has ceased to reign: its existence is incompatible with the repose of Europe, and the honour of our crown." By virtue of a decree which passed in March 1808, the emperor Napoleon conferred the kingdom of Naples on his highness prince Joseph and his legitimate heirs male, reserving to that prince the rights assured to him by the constitutions of the empire, by providing always that the crown of France and that of Naples shall never be united upon the same head.

Naples, a city of Italy, capital of a kingdom of the same name, and an archbishop's see, with a university. It is seated on the bay of Naples, and built in the form of a vast amphitheatre, sloping from the hills to the sea. Although the style of architecture is inferior to what prevails at Rome, and it cannot vie with that city in the number of palaces, or in the magnificence of the churches, the private houses, in general, are better built, and the streets are broader and better paved. The houses, in general, are five or six stories high, and flat at the top; on which are placed numbers of flower vases, or fruit trees, in boxes of earth. The fortress of St. Elmo is built on a mountain of the same name, and has the entire command of the town. Lower down on the same mountain, in a delightful situation, is the convent of Carthusians, on which much expence has been lavished, to render the building and the gardens equal to the situation. Naples is well situate for commerce, and has all the necessaries and luxuries of life in great profusion; but trade is in a languishing condition. The chief articles manufactured here are silk stockings, soap, snuff-boxes of tortoise-shell and lava, and tables and ornamental furniture of marble. They are thought to embroider here better than in France; and their macaroni, confections, and cordials are in the highest esteem. The inhabitants are computed to be 380,000, which is very probable; for though Naples is not one-third of the size of London, yet many of its streets are more crowded, and a great proportion of the poorest sort spend the night in them for want of habitations. There is not a city in the world, perhaps, with the same number of inhabitants, in which so few contribute to the wealth of the community, by useful and productive labour, as Naples; for the number of priests, monks, fiddlers, lawyers, nobility, footmen, and lazzaroni, or vagabonds, surpasses all reasonable proportion; and the last alone are computed at above 30,000. The nobility are excessively fond of splendor and show: as appears by the brilliancy of their equipages, the number of their attendants, the richness of their dress, and the grandeur of their titles. The king, it is said, counts a hundred persons with the title of prince, and still a greater number with that of duke, among his subjects. A few of these have estates from 10 to 13,000*l.* a year; a considerable number have fortunes of about half that amount; and the annual revenue of many is under 2000*l.* The inferior orders of nobility are much poorer; many counts and marquises not having 400*l.* a year paternal estate; many still less; and not a few enjoy the title without any estate whatever. Although the churches and convents of Naples are not to be compared with those at Rome in point of architecture and in paintings; yet they surpass them in rich jewels, and in the quantity of silver and golden crucifixes, vessels, and other ornaments. The cathedral is a noble Gothic edifice, in which are kept the head and some of the blood of St. Januarius, the tutelary saint of Naples, but his body lies under the altar. This dried blood is preserved in two small crystal vials, and on some extraordinary occasions is with great solemnity brought near the head of the saint, when by a supposed miracle it liquefies, and thereby is deemed to be a happy presage; but if the blood retains its dryness the people are struck with terror. Of all the palaces, that of the king is not only the most magnificent, but in the best style of architecture. The harbour, which is spacious, is protected by a mole, two castles, and several batteries; but these could not protect the city from a bombardment. The bay of Naples is one of the finest in the world, being almost of a circular figure, 30 miles in diameter; shut out from the Mediterranean by the island of Capri, and three parts of it sheltered by a noble circuit of woods and mountains. Naples was taken by the French in 1799, and retaken by the Austrians and Russians, aided by a British fleet; but the French shortly afterward regained the possession. In 1803 the city suffered much damage by an earthquake. It is 110 miles S.E. of Rome. Lon. 14. 17 E. Lat. 40. 50 N.

Naples-yellow, called also Neapolitan earth, in Italian *Giallolino*, and in French *Jaune de Naples*, is a beautiful pigment, concerning which we have much information from the indefatigable Beckmann. "It has (says he) the appearance of an earth, is of a pale orange-yellow colour, ponderous, granulated, exceeding friable, does not become moist when exposed to the air, but when applied to the tongue seems to adhere to it. When reduced to a fine powder, it remains for some time suspended in water, but soon deposits itself the bottom in the form of a slime. When boiled with water, the water, at least sometimes, is observed to have a somewhat saline taste. It does not effervesce with acids, but is in part dissolved by aqua regia (nitro-muriatic acid). In the fire it emits no sulphureous vapour, is difficult to be fused, and by that operation undergoes no material change, only that its colour becomes somewhat redder. When fused with colourless glass, it gives it a milk-white colour, a sure proof that it contains no iron; and, with inflammable substances, there is obtained from it a regulus which has the appearance of a mixture of lead and antimony.

"This article is brought from Naples for the most part in the form of an earthy crust, about three or four lines in thickness, and it sometimes retains the form of the vessel in which it has hardened. It can be procured also as a fine powder, as the colourmen keep it sometimes ready pounded for use."

About the nature of the substance called Naples-yellow there has been much diversity of opinion. Most of those who have written about it consider it as originating from fire, and as a volcanic production of Mount Vesuvius or Mount Ætna; others have pronounced it to be a natural ochre. Guettard thought it rather a kind of bole; but Pott approached nearest the truth, by asserting it to be an artificial preparation. Fougeroux is entitled to the merit of having proved this, and of having shewn the possibility of preparing it. According to his experiments, Naples-yellow will be obtained, if you boil for seven or eight hours, first over a slow and then over a strong fire, a mixture finely pulverised of twelve parts of pure white lead, one part of alum, one part of sal ammoniac, and three parts of diaphoretic antimony (white oxyd of antimony by nitre). But before Fougeroux, who may have obtained an account of the process during his travels through Italy, a more certain process was published in the year 1758 by Giambattista Passeri, in his interesting work on the painting of earthen-ware. The articles to be employed, according to this author, are, "one pound of antimony, a pound and a half of lead, one ounce of alume di feccia, and the same quantity of common salt." "I am inclined (says M. Beckmann) to think that this receipt was not unknown to Fougeroux, and that he considered alume di feccia to be alum. Professor Leonhardi, a man of very sound learning, has translated this expression by the word alum. I will, however, freely confess, that I consider alume di feccia not to mean alum, but salt of tartar, or potash. Passeri says, that the proportions may bè varied different ways; and he gives six other receipts, in which he does not mention alume di feccia, but only feccia; and this word certainly means weinhefen or winestone (tartar). Professor Leonhardi himself seems to confirm this opinion, by saying, that Vairo, professor of chemistry at Naples, has translated "the ashes of wine lees" (cineres infectorii) by the words alume di feccia.

NAPLESS. *a.* (from *nap.*) Wanting nap; threadbare (*Shakspeare*).

NAPOLI DI MALVASIA, a sea-port of European Turkey, in the Morea, capital of the island of Malvasia. It has a fine harbour, defended by a good citadel; and a long wooden bridge, which joins it to the mainland. It gives name to that excellent wine, called Malmsey; and was the ancient Epidaurus, famed for the temple of Æsculapius. It is seated on a rock, at the entrance of the bay of Napoli de Romania, 38 miles S.E. of Misitra. Lon. 22. 58 E. Lat. 36. 53 N.

Napoli de Romania, a sea-port of European Turkey, in the Morea, and an archbishop's see, seated on a peninsula, at the head of a bay of the same name. It is inhabited by 60,000 Greeks, beside people of different nations; and has a large harbour, with a narrow entrance defended by a citadel. This town was taken by the Turks in 1715. It is 20 miles S.S.W. of Corinth. Lon. 22. 44 E. Lat. 37. 44 N.

NA'PPINESS. *s.* (from *nappy.*) The quality of having a nap.

NA'PPY. *a.* (from *nap.*) Frothy; spumy (*Gay*).

Nappy. Tomentose. Tomentosus. In botany, covered with a whitish down, or with hairs interwoven and scarcely distinguishable. As the leaves of cerastium tomentosum, &c.

NA'PTAKING. *s.* (*nap* and *take.*) Surprise; seizure on a sudden (*Carew*).

NAPUS. (*napus*, ναπος; from *napus*, Rabb.). Napus sylvestris. Bunias. Wild navew or rape. Brassica napus of Linnéus. The seeds yield upon expression a large quantity of oil, called rape oil, which is sometimes ordered in stimulating liniments. See Brassica.

NAR, a river of Umbria, whose waters, famous for their sulphureous properties, pass through the lake Velinus, and issuing from thence with great rapidity fall into the Tiber.

NARBO, a town of Gaul, founded by the consul Marcius, A. U. C. 634. It became the capital of a large province of Gaul, which obtained the name of Gallia Narbonensis.

NARBONENSIS GALLIA, one of the four great divisions of ancient Gaul, and was bounded by the Alps, the Pyrenean mountains, Aquitania, Belgicum, and the Mediterranean.

NARBONNE, an ancient city of France, in the department of Aude and late province of Languedoc. Before the revolution of 1789 it was an archiepiscopal see. In the time of the Romans it was the capital of that part of Gaul called Gallia Narbonensis; and here the emperor Marcus Aurelius was born. Some Roman inscriptions, in different parts of the city, are still visible; and the canal, from the river Aude, through the city, to the Mediterranean, was cut by the Romans. Narbonne is famous for its honey; and the cathedral is remarkable for its noble choir. It is five miles from the Mediterranean, and 75 E. by S. of Toulouse. E. lon. 3 6. N. lat. 43 11.

NARCISSA LEUCOIUM. See Leucoium.

NARCISSUS, in fabulous history, the son of the river Cephissus and Liriope the daughter of Oceanus, was a youth of great beauty. Tiresias foretold that he should live till he saw himself. He despised all the nymphs of the country; and made Echo languish till she became a mere sound, by refusing to return her passion: but one day coming weary and fatigued from the chace, he stopped on the bank of a fountain to quench his thirst; when, seeing his own form in the water, he became so in love with the shadow image, that he languished till he died. On which the gods, being moved at his death, changed him into the flower which bears his name.

Narcissus, in botany, a genus of the class hexandria, order monogynia. Corol superior, six-petalled, equal; nectary funnel-form, one-leafed, bearing the petals; stamens within the nectary: stigma three-cleft. Twenty-three species, all European plants, and three or four natives of our own country. The following are those chiefly cultivated.

1. N. pseudo-narcissus. Common daffodil.
2. N. poeticus. White narcissus.
3. N. biflorus. Two-leaved narcissus, or pale daffodil.
4. N. briolor. Two-coloured narcissus.
5. N. minor. Least daffodil.
6. N. triandrus. Rush-leaved narcissus, or reflected daffodil.
7. N. orientalis. Oriental narcissus.
8. N. bulbocodium. Hoop-petticoat narcissus.
9. N. tazetta. Polyanthus narcissus.
10. N. serotinus. Late-flowering narcissus.
11. N. odorus. Sweet-scented narcissus.
12. N. calathinus. Calathine, yellow narcissus.
13. N. jonquilla. Common jonquil.

Of these some have the petals and nectaries of equal length, with filiform leaves. A second tribe have the petals twice as long as the nectary, with nodding flowers. A third tribe the petals three times as long as the nectary; the spathes few-flowered. A fourth tribe petals three times as long as the nectary, with a many-flowered spathe.

The bastard narcissus, or common yellow English daffodil, grows wild in our woods and under our hedges. Common as it is, it is an elegant flower, and the more worthy of notice from its hardiness, early appearance, and easy culture as a double flower.

The narcissus poeticus yields many varieties, purple-cupped flowers, yellow-cupped flowers, double-flowers, the petals in all of them being entire and white. It derives its specific name from its being the real narcissus of the Greek and Roman poets, and deservedly extolled by them for its great beauty and fragrance.

The tazetta, or polyanthus daffodil, yields also a great multitude of varieties, amounting in the Dutch catalogues to upwards of a hundred. They are all beautiful flowers, and afford a charming appearance, whether the borders of flower-gardens, or in glasses of water, or ornamental pots as a decoration to drawing rooms.

The jonquil exhibits, in like manner, a very considerable variety, and in every variety, on account of its delicacy of shape, softness of colour, and sweetness of scent, is among the most agreeable of the flowers presented to us in the vernal months.

Most of these may be propagated either by offsets or by seeds. If offsets, such as have been with the parent root three years in the ground should be chosen, taken off in August, and planted at ten inches distance. The method by seeds is in all respects preferable, and is in general such as must be used for all the narcissus kinds, with only a few peculiarities. The seeds should be obtained from the countries in which this plant grows naturally, and such seeds should be carefully collected from good flowers. They must be sown the first week in September, in boxes of a light, rich compost, and set where they can have free air, and the morning sun. In winter the boxes should be removed into a southern aspect, and towards April be taken back into their first place again. In spring the young plants will appear, and they must be kept clear of weeds, and sometimes gently watered. Towards autumn they will fade, when a quarter of an inch thick of the same compost should be sifted over them. The third year they must be separated from the earth by sifting, and planted out in a place sheltered from the winds, and not open to the full sun. The beginning of August is the best time for planting them; the beds must after this be kept clear from weeds, and five weeks after they must have a fresh covering of an inch deep of the same compost. In this bed they will flower, and they should stand at a foot distance, and not be taken up till the fourth year.

NARCISSUS (Autumnal). See AMARYLLIS.

NARCOSIS. (*narcosis*, f. ναρκωσις; from ναρκοω, to stupefy.) Stupefaction, stupor, numbness.

NARCO'TIC. *a.* (ναρκοω, *narcotique*, Fr.) Producing torpor, or stupefaction.

NARCOTIC PRINCIPLE in PLANTS. It has long been known that the milky juices which exude from certain plants, as the poppy, lettuce, &c. and the infusions of others, as the leaves of the digitalis purpurea, have the property of exciting sleep, or if taken in large enough doses, of inducing a state resembling apoplexy, and terminating in death. How far these plants owe these properties to certain common principles which they possess is not known; though it is exceedingly probable that they do. But as a peculiar substance has been detected in opium, the most noted of the narcotic preparations, which possesses narcotic properties in perfection, we are warranted, till further experiments elucidate the subject, to consider it as the narcotic principle, or at least as one species of the substances belonging to this genus.

Opium is obtained from the papaver album, or white poppy, a plant which is cultivated in great abundance in India and the East. The poppies are planted in a fertile soil and well watered. After the flowering is over, and the seed capsules have attained nearly their full size, a longitudinal incision is made in them about sun-set for three or four evenings in succession. From these incisions there flows a milky juice, which soon concretes, and is scraped off the plant and wrought into cakes. In this state it is brought to Europe.

Opium thus prepared is a tough brown substance, has a peculiar smell, and a nauseous bitter acrid taste. It becomes softer when held in the warm hand, sand burns very readily and strongly. It is a very compound substance, containing sulphate of lime, sulphate of potash, an oil, a resinous body, an extractive matter, gluten, mucilage, &c. besides the peculiar narcotic principle, to which probably it owes its virtues as a narcotic.

Almost all the medical chemists have published analyses of opium. To their labours indeed we are indebted for every thing concerning it at present known. Newmann, Hoffman, Trulles, Baumé, have distinguished themselves most; and more lately remarks have been published on it by Josse, Buchole, Proust, and Dèrosne. The dissertation of the last is peculiarly valuable. He first pointed out the nature and properties of the narcotic principles of opium. It had indeed been noticed by most of the elder chemists, though they had formed erroneous opinions respecting its nature. When water is digested upon opium a considerable portion of it is dissolved, the water soaking up several of its constituents. When this solution is evaporated to the consistence of syrup, a gritty precipitate begins to appear, which is considerably increased by diluting the liquid with water. It consists chiefly of three ingredients; namely, resin, oxigenized extractive, and the peculiar narcotic principle, which is crystallized. When alcohol is digested on this precipitate, the resin and narcotic substance are taken up, while the oxygenized extractive remains behind. The narcotic principle falls down in crystals as the solution cools, still however coloured with resin.

But it may be obtained tolerably pure by repeated solutions and crystallizations. Water is incapable of dissolving the whole of opium. What remains behind still contains a considerable portion of narcotic principle. When alcohol is digested on this residuum it acquires a deep red colour; and deposites on cooling crystals of narcotic principles, coloured by resin, which may be purified by repeated crystallizations. The narcotic principle obtained by either of these methods possesses the following properties.

1. Its colour is white. It crystallizes rectangular prisms with rhomboidal bases. It has neither taste nor smell.

2. It is insoluble in cold water, soluble in about 400 parts of boiling water, but precipitates again as the solution cools. The solution in boiling water does not affect vegetable blues.

3. It is soluble in 24 parts of boiling alcohol and 100 parts of cold alcohol. When water is mixed with the solution, the narcotic principle precipitates in the state of a white powder.

4. Hot æther dissolves it, but lets it fall on cooling.

5. When heated in a spoon it melts like wax. When distilled it froths and emits white vapours, which condense into a yellow oil. Some water and carbonate of ammonia pass into the receiver; and at last carbonic acid gas, ammonia, and carburetted hydrogen gas, are disengaged. There remains a bulky coal, which yields traces of pot-ash. The oil obtained by this process is viscid, and has a peculiar aromatic smell, and an acrid taste.

6. It is very soluble in all acids. Alkalies throw it down from these solutions in the state of a white powder.

7. Alkalies render it rather more soluble in water. When they are saturated with acids, the narcotic principle falls down in the state of a white powder, which is redissolved by adding an excess of acid.

8. Volatile oils while hot dissolve it, but on cooling they let it fall in an oleaginous state at first, but gradually crystallizes.

9. When treated with nitric acid it becomes red and dissolves; much oxalic acid is formed, and a bitter substance remains behind.

10. When potash is added to the aqueous solution of opium, the narcotic principle is thrown down; but it retains a portion of the potash.

11. Its solubility in water and alcohol, when immediately extracted from opium, seems to be owing to the presence of resin and extractive matter, both of which render it soluble.

12. It possesses the properties of opium in perfection. Dèrosne tried it upon several dogs, and found it more powerful than opium. Its bad effects were counteracted by causing the animals to swallow vinegar. This substance is known to be of equal service in counteracting the effects of opium. Dèrosne supposes that the efficacy of vinegar may be owing to the readiness with which it dissolves the narcotic principle. Many other substances besides opium possess narcotic virtues, but hitherto they have not been examined by chemists with much attention. The most remarkable are the following:

1. The lactuca virosa, and the sativa, or garden lettuce, and indeed all the lactucas, yield a milky juice, which, when inspissated, has very much the appearance of opium, and possesses the same properties. Indeed Dr. Coxe of Philadelphia affirms, that as good opium may be obtained from the garden lettuce as from the poppy. The milky juice is obtained by incisions at the time when the lettuce is running to seed. The resemblance between the inspissated juice of the lactuca virosa and opium is striking.

2. The leaves of the atropa belladonna, deadly nightshade, and indeed the whole plant, are remarkably narcotic; and when taken in too great doses produce blindness, convulsions, coma, and death.

3. The leaves of the digitalis purpurea, or fox-glove, are still more powerful, if possible. They lower the pulse in a remarkable degree, and like several other very poisonous narcotics, promote the discharge of urine.

4. The hyoscyamus niger, or hen-bane.

5. Canium maculatum, or hemlock.

6. Datura stramonium.

7. Ledum palustre.

To these may perhaps be added the prunus laurocerasus, and the leaves of nicotiana tabacum, or tobacco. The list indeed might be easily increased: almost all the plants belonging to the natural order of the lurida possessing narcotic properties: but as we are completely ignorant of the chemical properties of these plants, it is unnecessary to be more particular.

NARCOTICS. (*narcotica, medicamenta*; from ναρκοω to stupefy.) See ANODYNES.

NARD (Celtic.) See NARDUS CELTICA.

NARD (Indian). See NARDUS INDICA.

NARDUS. Matgrass. In botany, a genus of the class triandria, order monogynia. Calyxless; corol a two-valved glume. Three species, as follows:

1. N. striata. Spike slender, erect, pointing one way. Common to our heaths.

2. N. aristata. Glumes of the calyx awned. Florets slightly peduncled in pairs. Indigenous to the south of Europe.

3. N. ciliaris. Spike incurved, ciliate on the edge. Leaves grassy, flat; florets on the outer valve, ovate-oblong, awnless, with a short bristle on each side.

It is customary under this article to descant on the value attached to the nardus, as a perfume, by the Greeks, and Romans, and indeed by all the oriental countries from which they undoubtedly derived it. But we shall forbear all such discussions till we learn to a certainty what is the plant referred to under this name by the Greek and Roman poets: we are confident it does not belong to the genus before us; and sir William Jones has very plausibly attempted to prove that it was a species of valerian.

Nardus. (*nardus*, ναρδος; from *nard*, Syr.) Spikenard.

Nardus celtica. Spica celtica. Celtic nard. Valeriana celtica of Linnéus. The root of this plant, a native of the Alps, has been recommended as a stomachic, carminative, and diuretic. At present it is only used in this country in the theriaca and mithridate, though its sensible qualities promise some considerable medicinal powers. It has a moderately strong smell, and a warm, bitterish, sub-acrid taste.

Nardus indica. Spica nardi. Spica indica. Indian nard, or spike-nard. The root of this plant, andropogon nardus of Linnéus, is an ingredient in the mithridate and theriaca; it is moderately warm and pungent, accompanied with a flavour not disagreeable. It is said to be used amongst the orientals as a spice.

Nardus rustica. An old name of the asarabacca. See Asarum.

NAREA, the most southerly province of the empire of Abyssinia; a kingdom still governed by its own princes, who have the title of Beneros. Its territory was formerly more extensive than at present, the Galla having almost quite surrounded it, especially on the south-east and north. The country to the west is the most unknown part of Africa; the kingdom itself stands like a fortified place in the middle of a plain, being an high and mountainous country, A great many rivers, rising in the fourth and fifth degrees of north latitude, spread themselves over the level part of the country, and fill it with marshes all the way from south by east to north, or north-west.—These marshes are bounded by mountains, of which those nearest the marshes are overgrown with coffee-trees, the largest, if not the only ones, which grow in this country. The kingdom of Narea Proper is interspersed with small, unwholesome, but very fertile valleys.

NARES. (*naris*, a nostril.) In anatomy, the nostrils. The cavity of the nostrils is of a pyramidal figure, and is situated under the anterior part of the cranium in the middle of the face. It is composed of fourteen bones, viz. the frontal, two maxillary, two nasal, two lachrymal, two inferior spongy, the sphænoid, the vomer, the ethmoid, and two palatine bones, which form several eminences and cavities. The eminences are the septum narium, the cavernous substance of the ethmoid bone, called the superior conchæ, and the inferior spongy bones. The cavities are three pair of pituitary sinuses, namely, the frontal, sphænoid and maxillary; the anterior and posterior foramina of the nostrils; the ductus nasalis, the sphænopalatine foramina, and anterior palatine foramina. All these parts are covered with periosteum, and a pituitary membrane which secretes the mucus of the nostrils. The arteries of this cavity are branches of the internal maxillary. The veins empty themselves into the internal jugulars. The nerves are branches of the olfactory, ophthalmic, and superior maxillary. The use of the nostrils is for smelling, respiration, and speech.

Nares (James), doctor of music, and brother to judge Nares, was born at Stanwell, 1715. He was one of the choristers of the royal chapel, and in 1734 became organist at York. In 1755 he was organist and composer to the king, in the room of Dr. Green, and the next year he took his musical degree at Cambridge, and in 1757 was made master of the chorists, which he resigned in 1780 to his pupil Dr. Ayrton. He died 1783. His works are much admired, especially the royal pastoral, an ode.

NARIS COMPRESSOR, in myology. See Compressor naris.

NA'RRABLE. *a.* (from *narro*, Lat.) Capable to be told or related.

To NA'RRATE. *v. a.* (*narro*, Latin.) To relate; to tell.

NARRA'TION. *s.* (*narratio*, Latin.) Account; relation; history (*Abbot*).

NA'RRATIVE. *a.* (*narratif-ve*, French; from *narro*, Latin.) 1. Relating; giving an account (*Ayliffe*). 2. Storytelling; apt to relate things past (*Pope*).

Na'rrative. *s.* A relation; an account; a story (*Tatler*).

NA'RRATIVELY. *ad.* (from *narrative.*) By way of relation (*Ayliffe*).

NARRA'TOR *s.* (*narrateur*, French.) A teller; a relater (*Watts*).

NA'RROW. *a.* (nearu, Saxon). 1. Not broad or wide (*Shakspeare*). 2. Small; of no great extent (*Brown*). 3. Covetous; avaritious (*Sidney*). 4. Contracted; ungenerous (*Sprat*). 5. Near; within a small distance (*Dryd.*). 6. Close; vigilant; attentive (*Milton*).

Narrow-chested. In the menage, a horse is so called, whose breast is so narrow (when standing before him) that the fore-legs gradually extend wider in proportion as the eye accompanies them nearer the ground; so that, in a front view, they bear the form of two legs of a common country washing-stool, where the legs are inserted in the narrow part of the wood at the top, and are four or five inches more in width at the bottom. Horses of this description are invariably weak before; and when put into hard work, or severe exertion, are the very sort of which so many upon the roads are seen in a chest-foundered state. See Chest foundered.

To **Na'rrow.** *v. a.* 1. To diminish with respect to breadth (*Temp.*). 2. To contract; to impair dignity (*Locke*). 3. To contract in sentiment (*Pope*). 4. To confine; to limit (*Watts*). 5. (In farriery.) A horse is said to *narrow* when he does not take ground enough.

NA'RROWLY. *ad.* (from *narrow.*) 1. With little breadth or wideness. 2. Contractedly; without extent (*Swift*). 3. Closely; vigilantly (*Shaksp.*). 4. Nearly; within a little (*Swift*). 5. Avaritiously; sparingly.

NA'RROWNESS. *s.* (from *narrow.*) 1. Want of breadth or wideness (*Addison*). 2. Want of extent, or comprehension (*Locke*). 3. Confined state; contractedness (*Denham*). 4. Meanness; poverty (*South*). 5. Want of capacity (*Burnet*).

NARTHECIUM. Lancashire asphodel. In botany, a genus of the class hexandria, order monogynia. Corol six-petalled, spreading, permanent; filaments filiform, bearded; capule superior, prismatic; seeds appendaged each side; calyxless. One species, indigenous to the bogs of our own country.

NARVA, a strong town of the Russian empire, in Livonia, with a castle and a harbour. It was taken by the Muscovites from the Danes in 1558, by the Swedes in 1581, and they defeated the Muscovites near it in 1700; but it was retaken by the Russians in 1704 by storm, and the inhabitants sent to Astracan. It is seated on the river Narva, 95 miles S.W. of Wiburg, and 172 N.E. of Riga. Lon. 29. 0 E. Lat. 59. 8 N.

NARVAL, in mastiology. See CETE.

NAS. (from *ne has*, or *has not*.) *Spenser*.

NA'SAL. *a*. (*nasus*, Latin.) Belonging to the nose (*Sharp*).

NASALIS, in myology. See COMPRESSOR NARIS.

NASEBY, a village in Northamptonshire, famous for the decisive victory gained by the army of the parliament over that of Charles I., in 1645. It is 12 miles N. of Northampton.

NASHVILLE, a town of the state of Tennassee, capital of the district of Mero, seated on Cumberland river, 160 miles E. of Knoxville. Lon. 87. 20 W. Lat. 36. 2 N.

NASH (Richard), an extraordinary character, born in Glamorganshire, 1764. From Carmarthen school he went to Jesus college, Oxford, where he became known more for his love of pleasure than for his application. He entered the army, and obtained a pair of colours; but soon relinquished this for a town life, and the law at the Temple. Admired as a jovial companion, he became the arbiter elegantiarum of the fashionable world, and when the Middle Temple, according to custom, exhibited an entertainment for king William, Nash managed the ceremony so well, that the monarch offered him the honour of knighthood, which he declined. In 1704 Nash went to Bath, and being elected master of ceremonies, he soon made that city the resort of the gay, the fashionable, and the opulent. The greatest regularity was made to prevail in the public rooms, and Bath, lately known to few, became the centre of attraction for persons in the higher rank of life. Nash supported his expences chiefly from the gaming table; but with this vicious propensity, he was humane, generous, and charitable, and though persecuted by creditors, he has often bestowed on the cravings of indigence what was due from him to patient industry. Flattered with the appellation of the king of Bath, and called beau Nash, he continued his career of genteel, or, as it should rather be termed, profligate dissipation, though his income was precarious, and his resources depended on chance. In the decline of life he became very poor, and the presents, formerly received from the partiality of the great, were all disposed of to support his necessities. His last moments brought with them, as might be expected, unpleasing reflections, and he expired in great agitation of mind, 1761, aged 87. As he had contributed to the celebrity of Bath, and promoted the building of an hospital, the people of the city shewed due respect to his remains there. A striking letter written to this celebrated fop, in order to convince him that he had a soul which must appear undressed in the presence of the Great Judge, may be seen in Dodd's Reflections on Death, page 111.

NASI DEPRESSOR. See DEPRESSOR LABII SUPERIORIS ALÆQUE NASI.

NASI OSSA. (*nasus*.) The two small bones of the nose that are so termed form the bridge of the nose. In figure they are quadrangular and oblong.

NA'SICORNOUS. *a*. (*nasus* and *cornu*.) Having the horn on the nose (*Brown*).

NASSAU, a county of Germany, in the circle of Upper Rhine; bounded on the N. by Westphalia, on the E. by the county of Solmes, on the S. by the territory of Mentz, and on the W. by the electorate of Treves. It is very fertile, and contains mines of iron, copper, and lead.

NASSAU, a town of Germany, capital of a county of the same name, the house of whose sovereign is divided into several branches. It is seated on the river Lahn, 12 miles S.E. of Coblentz. Lon. 7. 42 E. Lat. 50. 18 N.

NASSAUVIA, in botany, a genus of the class syngenesia, order polygamia segregata. Flowers clustered into a head, mixed with intervening scales; calyx four or five-flowered, double; the outer three-leaved, inner five-leaved; florets tubular, somewhat two-lipped, all hermaphrodite; receptacle naked, seeds crowned with four or five deciduous bristles. One species, a native of Magellan's Straits; stem ascending, clothed with imbricate leaves; flowers terminal, invested with ovate, acute scales.

NA'STILY. *ad*. (from *nasty*). 1. Dirtily; filthily; nauseously (*Bacon*). 2. Obscenely; grossly.

NA'STINESS. *s*. (from *nasty*.) 1. Dirt; filth (*Hayward*). 2. Obscenity; grossness of ideas (*South*).

NASTURTIUM. See NASTURTIUM INDICUM and TRAPÆOLUM.

NASTURTIUM AQUATICUM. (*nasturtium, quod nasum torquent*, because the seed when bruising irritates the nose). Water cresse. This indigenous plant, sisymbrium nasturtium of Linnéus, sisymbrium siliquis declinatis, foliis pinnatis, foliolis subcordatis, class tetradynamia, order siliquosa, grows plentifully in brooks and stagnant waters. The leaves have a moderate pungent taste, emit a quick penetrating smell, like that of mustard-seed, but much weaker. Water-cresses obtain a place in the materia medica for their antiscorbutic qualities, which have been long very generally acknowledged by physicians. The most pleasant way of administering them is in form of salad. See SISYMBRIUM.

NASTURTIUM HORTENSE. Dittander.

This plant is the lepidium sativum floribus tetradynamiis; foliis oblongis, multifidis of Linnéus: it possesses warm, nervine, and stimulating qualities, and is given as an antiscorbutic, antiseptic, and stomachic, especially by the lower orders. See Lepidium.

Nasturtium Indicum. Greater Indian cress, or nasturtium. Trapæolum majus of Linnéus. This plant is a native of Peru; it was first brought to France in 1684, and there called La grande capucine. In its recent state this plant, and more especially its flowers, have a smell and taste resembling those of water-cress; and the leaves, on being bruised in a mortar, emit a pungent odour, somewhat like that of horse-radish. By distillation with water they impregnate the fluid in a considerable degree with the smell and flavour of the plant. Hence the antiscorbutic character of the nasturtium seems to be well founded, at least as far as we are able to judge from its sensible qualities: therefore in all those cases where the warm antiscorbutic vegetables are recommended, this plant may be occasionally adopted as a pleasant and effectual variety. Patients to whom the nauseous taste of scurvygrass is intolerable may find a grateful substitute in the nasturtium. The flowers are frequently used in salads, and the capsules are by many highly esteemed as a pickle. The flowers, in the warm summer months, about the time of sunset, have been observed to emit sparks like those of the electrical kind. See Trapæolum.

NA'STY. *a.* (*nast*, *nat*, German, wet.) 1 Dirty; filthy; sordid; nauseous (*Swift*). 2. Obscene; lewd.

NA'TAL. *a.* (*natal*, French.) Native; relating to nativity (*Camden*).

NATANT LEAF. In botany. A floating leaf. Placed on the surface of the water, in many aquatic plants; as nymphæa, potamogeton.

NA'TATION. *s.* (*natatio*, Lat.) The act of swimming (*Brown*).

NATATORY, in natural history, with legs or appendages formed for swimming.

NATES. (*nates*, from *nato*, to flow: because the excrements are discharged from them). In anatomy, the fleshy parts upon which we sit.

Nates cerebri. See Tubercula quadragemina.

NA'THLESS. *ad.* (*na*, that is, *not*, *the less*, Saxon.) Nevertheless: obsolete (*Milton*).

NA'THMORE. *ad.* (*na the more.*) Never the more: obsolete (*Spenser*).

NA'TION. *s.* (*nation*, Fr. *natio*, Latin.) 1. A people distinguished from another people. 2. A great number: emphatically (*Young*).

NA'TIONAL. *a.* (*national*, Fr. from *nation.*) 1. Public; general; not private; not particular (*Addison*). 2. Bigoted to one's own country.

National debt. See Debt and War.

NA'TIONALLY, *ad.* (from *national.*) With regard to the nation (*South*).

NA'TIONALNESS. *s.* (from *national.*) Reference to the people in general.

NATIONS. (See Gentes.) In natural history. The sense in which the word *cast* is used in the East Indies, best expresses the idea which Linnéus seems to have affixed to this word.

NA'TIVE. *a.* (*nativus*, Lat. *natif-ve*, Fr.) 1. Produced by nature; not artificial (*Davies*). 2. Natural; such as is according to nature; original (*Swift*). 3. Conferred by birth (*Denham*). 4. Pertaining to the time or place of birth (*Shakspeare*). 5. Original; that which gave being (*Milton*).

Na'tive. *s.* 1. One born in any place; original inhabitant (*Bacon*). 2. Offspring (*Shakspeare*).

NA'TIVENESS. *s.* (from *native.*) State of being produced by nature.

NATI'VITY. *s.* (*nativité*, French). 1. Birth; issue into life (*Bacon*). 2. Time, place, or manner of birth (*Shakspeare*). 3. State or place of being produced (*Milton*).

Nativity, in astrology, the scheme or figure of the heavens, and particularly of the twelve houses, at the moment when a person was born; called also the horoscope.

To cast the nativity, is to calculate the position of the heavens, and erect the figure of them for the time of birth.

NATOLIA, a country, formerly called Asia Minor. It is the most western part of Turkey in Asia, extending from the Euphrates as far as the Archipelago, the strait of Gallipoli, the sea of Marmora, and the strait of Constantinople. It is bounded on the N. by the Black Sea, and on the S. by the Mediterranean. The air is temperate and wholesome, and the soil generally fertile. It is crossed by a chain of mountains, formerly called Taurus, from E. to W, and watered by a great number of rivers.

NATRIX, in zoology. See Torquatas.

NATROLITE, in mineralogy, a species of zeolite possessing a crystalline form, but distinguished from the other species of zeolite by possessing a considerable quantity of soda, and no lime. See Zeolite.

NATRON. See Soda and Natrum.

Natron muriatum. See Murias sodæ.

Natron præparatum. Soda preparata. Sal sodæ. Alkali minerale aeratum. This salt consists of soda saturated with carbonic acid, and is therefore called carbonas sodæ in the new chemical nomenclature. It is given in doses of from ten grains to half a drachm as an attenuant and antacid; and, joined with bark and aromatics, it is highly praised by some in the cure of scrophula. It is likewise a powerful solvent of mucus, a deobstruent and diuretic, and an antidote against oxyd of arsenic and the corrosive sublimate. The other diseases in which it is administered are those arising from an abundance of mucus in the primæ viæ; calculous complaints, gout, some affections of the skin, rickets, tinea capitis, crusta lactea, and worms. Externally it is recommended by some in the form of lotion, to be applied to scrophulous ulcers. See Alkali minerale and Soda.

NATRON TARTARISATUM. Sal Rupellensis. Sal polychrestum Seignetti. Alkali minerale tartarisatum. This preparation is a combination of the acid of tartar with soda, and called in the new chemical nomenclature tartris sodæ. It possesses mildly cathartic, diuretic, and deobstruent virtues, and is administered in the dose of from half an ounce to an ounce as a cathartic, and in the dose of from twenty to thirty grains in abdominal physconia, and torpidity of the kidneys.

NATRON VITRIOLATUM. Alkali minerale vitriolatum. Sal mirabile seu catharticus Glauberi. Glauber's salt. This preparation being a sulphat of the mineral alkali is termed sulphas sodæ in the new chemical nomenclature. It possesses cathartic and diuretic qualities, and is in high esteem as a mild cathartic. It is found in the mineral kingdom formed by nature, but that which is used medicinally is prepared by art.

NATRUM, in mineralogy, a genus of the class salts: of a caustic taste, effervescing with acids, with oil forming soap, changing blue vegetable juices green, rendering acid solutions of earths and metals turbid. Four species.

1. N. antiquorum. Oriental alkali. Mineral alkali. Soda. Natron. Inodorous, dry, nearly pure. Found in China, Bengal, Persia, Syria, Egypt, South America, Denmark, Switzerland, and Hungary, generally during the spring and summer in a state of whitish efflorescent powder, and most usually combined with a greater or less portion of earth, common salt, acid and various substances; totally soluble in water, and after evaporation running into four-sided prismatic crystals, terminating on each side in needle-like points, which on exposure to the air soon moulder into a snowy impalpable powder; with quick-lime and oil forming soap, and with silica glass; easily melting in the fire.

2. N. acidulare. Acidulated mineral alkali. Inodorous, dissolved in water. Found in warm and acidulous baths of Seltzer and various parts of Germany, and in the lakes between Alexandria and Rosetta.

3. M. murorum. Aphronite. Calcareous alkali. Inodorous, mixed with carbonet of lime. Found in old walls cemented by lime, and sometimes in marble rocks, efflorescing like frost, and is not totally soluble in water.

4. M. volatile. Volalkali. Volatile alkali. Fetid aphronite. Halinitron. Fetid, mixed with earths and other salts. Found in various soils, in chalk, swinstone, argils, and often in the natron of old walls: its odour originating in the ammonia of decayed living bodies.

Natron, or soda, is also secreted very largely by animals of all kinds, and constitutes a part of almost all the secerned fluids of the body, as the tears, urine, matter of perspiration, bronchial mucus, &c.

It is also secreted very largely by an extensive family of plants, whose salts obtained by burning constitute, in a pure or impure state, a very considerable article of traffic, and is usually sold under the name of barilla, or kelp. The chief plants of this description are the following:

Salsola sativa, Lin. Salsola sonda. Lofling. Kali hispanicum supinum annuum fedi foliis brevibus. Kali d'Alicante. It grows abundantly on that part of the Spanish coast which is washed by the Mediterranean sea. This species is deservedly first enumerated by professor Murray, as it supplies all the best soda consumed in Europe, which by us is called Spanish or Alicant soda, and by the Spanish merchants barilla de Alicante.

Salsola soda, Lin. Kali majus cochleato semine. Le salicor. This species, which grows on the French Mediterranean coast, is much used in Languedoc for the preparation of this salt, which is usually exported to Sicily and Italy.

Salsola tragus, Lin. affords an ordinary kind of soda, with which the French frequently mix that made in Languedoc. This adulteration is also practised by the Sicilians, who distinguish the plant by the term salvaggia.

Salicornia herbacea, Lin. is common in salt marshes, and on the sea-shore, all over Europe. Linnæus prefers the soda obtained from this plant to that of all the others; but though the quantity of fossil alkali which it yields is very considerable, as a great portion of it is united with muriatic acid, it is mixed with much common salt.

Salicornia arabica, Lin. Mesembryanthemum nodiflorum, Lin. Plantago squarrosa, Lin. All these, according to Alpinus, afford this alkali. It has also been procured from several of the fuci, especially F. vesiculosus, and distinguished here by the name kelp. Various other marine plants might also be noticed as yielding barilla or soda by combustion; but the principal are confined to the genus salsola, and that of salicornia. The salsola kali, on the authority of Rauwolf, is the species from which the salt is usually obtained in eastern countries.

It is to be regretted, that the different kinds of soda which are brought to European markets have not been sufficiently analysed to enable us to ascertain with tolerable certainty the respective value of each; and indeed while the practice of adulterating this salt continues, any attempts of this kind are likely to prove fruitless. The best information on this subject is to be had from Jussica, Mascorelle, Cadet, Borlare, and Sestini. In those places where the preparation of soda forms a considerable branch of commerce, as on the coast of the Mediterranean, seeds of the salsola are regularly sown in a proper situation near the sea, which usually shoot above ground in the course of a fortnight. About the time the seeds become ripe the plants are pulled up by the roots, and exposed in a suitable place to dry, where their seeds are collected; this being done, the plants are tied up in bundles, and burned in an oven constructed for the purpose, where the ashes are then while hot continually stirred with long poles. The sa-fine matter, on becoming cold, forms a hard solid mass, which is afterwards broken in pieces of a convenient size for exportation.

The Spanish soda, of the best sort, is in dark-coloured masses, of a blueish tinge, very ponderous, sonorous, dry to the touch, and externally abounding with small cavities, without any offensive smell, and very salt to the taste; if long exposed to the air, it undergoes a degree of spontaneous calcination. The best French soda is also dry, sonorous, brittle, and of a deep blue colour, approaching to black. The soda which is mixed with small stones, which gives out a fetid smell on solution, and is white, soft, and deliquescent, is of the worst kind. The method of purifying this salt is directed in the London pharmacopœia, under the article of natron præparatum, and in the Edinburgh pharmacopœia under that of sal alkalinus fixus fossilis purificatus. The pure crystals, thus formed of Alicant barilla, are colourless, transparent, lamellated, of a rhomboidal figure, and one hundred parts are found to contain twenty of alkali, sixteen of aerial acid, and sixty-four of water; but upon keeping the crystals for a length of time, if the air be not excluded, the water evaporates, and they assume the form of a white powder. According to Inslin, one ounce of water at the temperature 62 of Fahr. dissolves five drams and fifteen grains of the crystals. The same author also found that this salt, though not so long as the vegetable alkali-natron, has been thought useful in scrophulous disorders, but it is seldom given in its simple state.

Soda, or the mineral alkali as it is termed, is in common use in the manufacture of glass and soap; and as the latter is an article of the materia medica, it will be proper to consider its medicinal effects in this place.

All the soaps, of which there are various kinds, are composed of expressed vegetable oils, or animal fats, united with alkaline lixivia. The sapo ex oleo olivæ et natro confectus of the London pharmacopœia, or the sapo albus crispanus of the Edinburgh pharmacopœia (white Spanish soap), being made of the finer kinds of olive oil, is the best, and therefore preferred for internal use. Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aretæus and others inform us, that the Greeks obtained their knowledge of its medical use from the Romans. Its virtues, according to Bergius, are detergent, resolvent, and aperient, and its use recommended in jaundices, gout, calculous complaints, and in obstructions of the viscera. The efficacy of soap, in the first of these diseases, was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in supplying the place of bile in the primæ viæ. The utility of this medicine in icterical cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, since it is now known, that gall-stones have been found in many after death, who had been daily taking soap for several months, and even years. Of its good effects in urinary calculous affections we have the testimonies of several, especially when dissolved in lime water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi; it is however only in the incipient state of the disease that these remedies promise effectual benefit, though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave soap was a general medicine; for as he attributed most complaints to viscidity of the fluids, he and most of the Boerhaavian school prescribed it, in conjunction with different resinous and other substances, in gout, rheumatism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

NATTAM, a town and fortress of the peninsula of Hindustan, in the country of Madura, 18 miles N. of Madura, and 45 S.S.W. of Trichinopoly. Lon. 78. 18 E. Lat. 10. 10 N.

NATTIER (John Mark le), a French painter. His designs for the Luxemburg gallery have been engraved and printed, folio, 1710. He was professor in the academy of painting, and was patronized by Lewis, but he declined the liberal invitations of the czar Peter to settle in Russia. He died 1766.

NA'TURAL. *a.* (*naturel*, French.) 1. Produced or effected by nature (*Wilkins*) 2. Illegitimate; not legal (*Temple*). 3. Bestowed by nature; nor acquired (*Swift*). 4. Not forced; not farfetched; dictated by nature (*Wotton*). 5. Consonant to natural notions (*Locke*). 6. Tender; affectionate by nature (*Shakspeare*). 7. Unaffected; according to truth and reality (*Addison*). 8. Opposed to violent: as, *a* natural *death*.

NATURAL ACTIONS. Natural functions. Those actions by which the body is preserved, as hunger, thirst, &c. See FUNCTION.

NATURAL CHARACTER of vegetables. That which delivers all possible certain characteristic marks of the fructification: and may therefore be used under any system or arrangement. Such characters are given by Linnéus in his Genera Plantarum; from the number, figure, situation, and proportion of the parts; rejecting taste, smell, colour and size.

NATURAL CLASS. An assemblage of several genuses of plants, agreeing in their parts of fructification, general appearance, and qualities. We have instances of such in the umbellatæ, verticillatæ, siliquosæ, leguminosa, compositæ, gramina, &c.

NATURAL HISTORY. The history of the natural products of the earth, whether minerals, vegetables, or animals; and bearing the same relation to natural philosophy as physiology does to physics. It has obviously therefore a near approach to various other studies; as for instance, those of oryctology, chemistry, comparative anatomy, zoonomy, husbandry, and gardening; and, but that it would tend to place the term in a different sense from that in which it has of late years been regarded, it might correctly enough be contemplated as that peculiar genus of science of which all the preceding are only species.

Natural history is a science both useful and entertaining: as it comprehends animals, vegetables, and fossils; air, earth, and sea, with all their inhabitants and productions; it may be said to include the knowledge of all nature, and to present an inexhaustible fund of inquiry and of amusement. It is intimately connected with all the other sciences; and with all the arts, from the simplest and rudest, to the most complicated and the most elegant. While we look around us, we cannot avoid becoming more or less acquainted with the manners of animals, the œconomy of vegetables, and the general appearances of nature. From an acquaintance with these many advantages have already accrued to man; and from a more intimate knowledge of them, many more may still be derived. The comfort and happiness of all ranks may, in some degree, be said to depend on the knowledge of natural history. The husbandman needs to know the characters of the tame animals which he employs; what advantages are to be derived from them; whether there are others that would suit his purpose better; where they are to be found; how they may be procured, and how supported; the qualities of the soil which he cultivates, and the means of managing and of improving it; the nature of the grain which he raises, and whether he might not, with advantage, substitute a different species for that in common use. Even the meanest mechanic must have a pretty accurate knowledge of many of the qualities of those natural objects with which his craft is connected. The fine arts, though usually considered as the peculiar province of imagination, depend greatly upon natural history. Both in music and painting, the study of nature alone can ensure success. In the writings of the poets, images are perpetually introduced from external nature; and allusions as frequently made to the manners and œconomy of the animal tribes. Many of the transformations, celebrated by Ovid, are founded on facts in the natural history of animals and plants; and Lucretius and Virgil are very minute in describing the habits of various tame animals, and many species of the vegetable kingdom: nor are such parts the least valuable of their writings. As modern poets have not the same machinery of gods and goddesses, nymphs, fawns, and satyrs, which were so serviceable to the heathen poets; as they cannot employ elves, witches, ghosts, or the wonders of enchantment, with so much advantage as the writers of the old romance; let them be more industrious in studying the scenes of Nature: these are so endlessly diversified, that they must always continue to afford abundance of the richest materials for the poet's art;—materials, which have this advantage over allegory and fiction, that they are durable as the constitution of things. By attending to this principle, Thomson, while he led the way to others, has procured for himself a distinguished place among those whose names are immortal.

From the vicissitudes of the seasons acting upon the senses; from the presence of surrounding objects; from the necessity of deriving from them food, clothing, and shelter, natural history must have been a study of the first importance to man, and attended to from the earliest periods of society, Before the invention of letters, however, the observations and the discoveries of individuals were neither likely to be communicated to those at a distance, nor recorded for the information of those that should come after. In a more polished state of society the case is widely different: and hence we find Alexander the Great decreeing a collection of animals for the examination of Aristotle; and wild beasts, from every quarter of the globe, produced and exhibited in the amphitheatres at Rome. Yet Aristotle is almost the only ancient writer on zoology that merits attention: for even Pliny and Ælian, with this great example before their eyes, offer us nothing but crude collections, discriminated with little taste or judgment, truth and falsehood being blended in one common mass: and for many succeeding years, from various causes, all Europe is well known to have been immersed in ignorance and credulity.

Though natural history was not one of the favourite studies of the revivers of literature; yet the scholars of that period displayed a degree of industry, which, to many of the triflers of the present day, may appear incredible. The voluminous labours of Gesner and Aldrovandus are illustrious instances. These are rude quarries from which some valuable materials may be dug by such as will undergo the fatigue, and possess the judgment necessary to turn them to a good account.

Towards the end of the last century the science began to be more generally cultivated. Among our countrymen, Ray, Woodward, Collinson, and Edwards, prosecuted its study with singular success, and have been followed in the same track by many others, scarcely inferior in industry or abilities; none of whom however are more entitled to praise than the indefatigable Pennant. But to the celebrated Linnéus is justly attributed the honour of having first formed natural history into a system: and he may hence perhaps be reckoned its greatest benefactor. The eloquent Buffon, by so happily uniting extensive knowledge, ingenuity, and elegance, hath also contributed, in a signal manner, to diffuse, among all the various ranks of society, an ardent desire to obtain a more intimate acquaintance with the same study: and his attempts have been ably seconded by those of Wildenow, Pulteney, Shaw, and Smith.

A science, when taken in its full extent, so intimately connected with all the necessary and the fine arts, forming the basis of the other sciences, and more useful than any of them for the ordinary purposes of life, can never be too generally or too industriously cultivated. It is with the utmost propriety therefore that books on natural history are put into the hands of the young. If such books can be rendered interesting (and there is no reason why they should not be), they cannot fail of being eminently useful. And it is under this impression that we have dilated ourselves in the present work to the utmost extent we have been able, so as to find space for a description in all instances sufficiently detailed to become attractive and produce effect; and have been cautious in selecting for our descriptions those species whose forms or habits, or other singularities, are most striking and worthy of notice: while we have uniformly introduced into the body of the work an easy explanation of those scientific or technical terms upon which the accuracy of the science in a great degree depends; which we have found it, indeed, impossible to exchange for others, and which we should not have exchanged if we could.

To the animal kingdom, however, we have and shall still continue to pay the greatest degree of attention, as the most interesting and perfect department of the whole. The variety of the parts of an animal body, the happy perfection of the structure in which these are united, the diversity of forms which this order of beings exhibits, the powers of feeling, motion, and action, with which they are endowed, and indeed all their qualities, and all the circumstances of their existence, concur to establish them in this transcendent rank among the works of creation. The mineral kingdom presents many beauties and wonders to our observation, and the more we investigate it, more beauties and wonders it developes. Yet its want of organization and life renders it the lowest of the three divisions of natural science. The vegetable department displays organization and life; the individuals belonging to it increase in size by growth, which enlarges all their parts in due proportion, and not by the simple accumulation of homogeneous matter; and it exhibits such a multiplicity of beautiful forms, and such variety, richness, and elegance of colouring, that it is to be considered as superior to brute matter, and as approaching much nearer to the dignity of the animal creation. But still, when from the contemplation of these two kingdoms of nature we raise our views to animals, a train of nobler objects appear before us; our curiosity is more powerfully excited; our attention more closely fixed; and our minds are elevated and enlightened by a set of new and grander ideas.

He who studies nature with a careless eye, only appears to distinguish the animal from the vegetable, and the vegetable from the mineral kingdom: he notices not the nice gradations by which these different orders of beings run, as it were, into one another; he marks only the more prominent features, and the more glaring colours: the more remarkable differences force themselves upon his observation; but he passes on too rapidly to discern, or even examine whether these are seeming or real, whether they are divided by a firm and insuperable barrier, or connected by intermediate links. It never occurs to the vulgar, that animals and vegetables may possibly be one order of beings, or that any of the vegetable tribes are nearly allied to some parts of the mineral kingdom. They would laugh to hear a philosopher declare himself at a loss to give such a definition of any one of these divisions as might absolutely exclude the others.

Yet philosophers have actually felt this difficulty, and still continue to feel it. When they find animals fixed to a particular spot, extremely imperfect in their powers of sensation, and displaying scarcely any instinct or sensorial power, they can hardly consider them as endowed with any principle superior in its nature to vegetative life. Again, when they observe plants unfolding to the rays of the sun their leaves or flowers, which shrink together at the fall of night; receding, as if afraid of injury from objects that approach them; and, in whatever situation the seed be sown, or the shoot planted, constantly growing in that direction in which they can best enjoy the influence of light and air; it appears at first sight almost unfair to deny this class of beings sensations, desires, and even design. The sensibility of the *mimosa*, the art of the *dionæa muscipula*, the affectionate care with which the leaves of the tamarind tree contract and wrap themselves round the tender fruit, to protect it from the nocturnal cold, are so many instances in which vegetables make an approach towards some of the most eminent characteristics of animals. The oyster and other shell fishes, and almost all zoophytes, though ranked in the animal kingdom, seem, again, to possess few of the privileges of animal life.

The analogies between animals and vegetables, which have been traced by philosophical observation, occasion other difficulties in the attempt to fix the boundary between these two kingdoms. The bodies, as well of plants as of animals, consist of fluids and solids; they have both vessels designed to contain the fluids, and glands to secrete different juices: while the blood circulates through the bodies of animals, the sap of vegetables ascends and descends, so as to produce the same effects on the vegetable, which the motion of the blood by the force of the heart and the arteries produces on the animal system. These are but a few of the resemblances which have been observed between the species of the animal and those of the vegetable kingdom. Almost every one of the parts common to animal bodies has been represented by one naturalist or another as matched by some correspondent part in vegetable bodies. Such analogies are sometimes plain and striking, and sometimes scarce perceptible, or merely imaginary. They afford, however, an agreeable subject of speculation; and it cannot be denied that they increase the difficulty of ascertaining the limits by which these two departments of nature are divided.

But, however numerous and strong the analogies between animals and vegetables, however difficult it may be to discern the precise line which separates the one kingdom from the other; yet the leading characteristics are sufficiently distinct. The privileges which animals enjoy above the other parts of the creation are in most instances highly conspicuous.

One of the most eminent of these privileges is their power of loco-motion. Klein, with sufficient propriety, assumes this as the great characteristic by which animals may be distinguished from the other orders of beings. It does not hold indeed in every instance, for there are some plants of a nature almost as wandering as the most migratory of the animal tribes; such as the *fragaria*, or strawberry, as a land-plant, and the *valisneria* as an aquatic: but these anomalies are not common, and vegetables may in general be regarded as destitute of loco-motion. They seem to enjoy a species of life, and display on many occasions a degree of sensibility, or something very like it; but they are fixed, each to a peculiar spot, where they spring up, expand into full growth, and at length wither and decay. Animals, without suffering any external impulse, readily move from place to place, by virtue of an inward principle, superior in its nature to vegetative life. Some enjoy this power or property in a more eminent degree than others; some are more disposed than the rest of their fellows to exert it; and some, again, possess the power in a very inferior degree, and discover but a very faint inclination to avail themselves of it. We admire the rapid flight of the eagle, and the swiftness of the horse and the greyhound; we observe many of the swiftest and most vigorous animals sink into lethargic indolence, till roused by some peculiarly powerful motive; the snail, the sloth, but more particularly the oyster, the limpet, and other shell-fishes, both in their powers of self-motion, and in their dispositions to exert them, rise but very little above those vegetables which are more remarkable for sensibility. This property, however, though not uniformly the same in all animals, seems to belong, in one degree or another, to every being that can be ranked in this class; and it is sufficient to distinguish them remarkably, in all the circumstances of their existence, from those from whom Nature has withheld it.

But this is not the only property on which the dignity of the animal character depends. To be capable merely of moving from one situation to another by virtue of their natural powers, would not greatly exalt this department of beings. A mineral or vegetable, with self-motion superadded to its other properties, would not be much superior in dignity to what it naturally is without any such addition. Sensation then is usually regarded as another characteristic of animals: it is intimately connected with their powers of loco-motion, and even necessary to prompt them to the exertion of those powers. Did I not feel, I should never be roused to action. Yet several vegetables, among which the mimosa or sensitive-plant is one of the most remarkable instances, appear to possess something like sensibility. It is scarce possible to determine upon what principle in their nature the emotions which these kinds of plants display on certain occasions may depend. Is it owing to something peculiar in the structure of their parts, or in the matter of which they are formed? or are they actually informed by a sentient principle? This is perhaps one of those intricate cases in which truth is removed from our view, even beyond the reach of experiment. Yet, if we may fairly venture on this occasion to reason from general analogy, we must conclude that these plants are equally destitute of a conscious, sentient principle with the other kind of the vegetable kingdom. The structure of their parts is not that of an animal, but of a vegetable body: they are, like other vegetables, fixed to a particular spot: in all their other characters, too, they resemble not animals but vegetables; and even those phænomena, in which it may be imagined that they display indications of sensibility, are of such a nature that no decisive inference can be deduced from them.

Animals are endowed with various organs and powers of sensation, which serve to make them acquainted with the different properties of surrounding objects. Most of them see, hear, taste, touch, and smell. They all possess these, or a part of these powers of sensation, in an unequivocal manner. The senses are not indeed equally perfect in all; and some species appear to enjoy only a part of them. In some animals, the sight, the hearing, the touch, the taste, or the smell, is remarkably dull; and in others exquisitely delicate and acute. The eye of the mole receives but a faint glimmer of light; the ear of the ass is insensible to the harmony or melody of sounds; the sight of the ounce, on the contrary, is wonderfully acute; and the touch of the spider exquisitely delicate. Possibly the same feelings may not communicate to all animals the same images and sentiments: what is sweet to one animal may perhaps be bitter to another; what is beautiful to one species, may appear to another ugly or disagreeable; an odour, which to this animal is sweet-smelling, may be a stench in the nostrils of that. All sensations, however, communicate to the animal some useful knowledge of the qualities of surrounding objects; some knowledge suitable to his character and his circumstances.

But sensibility requires the beings to whom it belongs to possess some superior powers. Organs of sensation serve merely to carry on an intercourse between some internal principle in the animal possessed of them, and external nature. This internal principle exalts animals highly above every other arrangement of beings; and is, besides, so much diversified in different kinds and species of animals, and in different individuals, as to create the most remarkable distinctions among them. Perception must be common to all animals; without it, organs of sensation would be useless. Perception is indeed scarce any thing else but another word for sensibility: the only difference seems to be, that the former is scarce so strongly expressive a term as the latter. Memory appears to be no less necessary to animals than perception; to receive impressions from external nature would be but a trifling privilege, were those impressions of so evanescent a nature as to be effaced the next moment after they were communicated. Animals, without this power, could perform no voluntary functions. To render them equal to such functions, it seems indispensably necessary that they be able to connect the past with the present. Accordingly, every animal whose manners and œconomy have been observed with any considerable degree of attention appears to be more or less capable of remembrance. The docility of the domestic animals is a sufficient proof that they are endowed with this faculty: the cunning, and even the ferocity of beasts of prey, prove the same fact with respect to themselves: the complex and wonderful œconomy of the bee, the beaver, the crow, the birds of passage in general, and various others of the inferior animals, whose manners have been often contemplated with admiration, shews that their retentive powers are remarkably tenacious of the impressions made upon them. The human species possess the faculty of memory in a very eminent degree; and the arts by which they have learned to improve and assist it, render it a more important feature in their character, than in that of any of the other species in the animal creation.

But we cannot conceive a being to possess the powers of perception and memory, and yet not be conscious of its existence: this consciousness must therefore be allowed to be another of the internal powers of animals. With the powers of perception, remembrance, and consciousness, animals are observed to be also endowed with certain affections, and to be susceptible of certain emotions. Joy, grief, love, hatred, gratitude, resentment, fear, courage, with a number of other similar principles, reside in the human breast, and are to man the great springs of action. The inferior animals appear to be susceptible of the same emotions, and capable of many both of the selfish and the social affections which distinguish the human character. But neither do all the species or individuals of any one kind possess all these affections and passions in the very same degree; nor are the dispositions and affections of the different kinds in any respect the same. One kind or species is ferocious and cunning; in another courage appears united with noble generosity: one is remarkable for sloth and listless inactivity; another is restlessly active: one is grateful, submissive, and affectionate; another of a froward, untameable spirit, insensible to kindness, and incapable of attachment: one is docile and intelligent; another dull and stupid. Besides these emotions, affections, and passions of a more generous and refined nature, animals are likewise subject to certain appetites and feelings of a different sort: such are the appetites for food, and for the procreation of the species; the sense of bodily pleasure, and of bodily pain. These are more uniformly common to animals in general than the former: to receive the requisite supplies of food, and to reproduce the species, are properties still more essential to the animal character than the more refined sentiments and affections.

The internal qualities which have been enumerated are generally allowed to be common to all the more perfect animals, although diversified in different species, and different individuals. But even these,—the power of self-motion, organs of sensation, perception, consciousness, memory, appetites, affections, and passions,—are not sufficient to complete the character: they need some other powers to call forth, to regulate, and to restrain their energy; something on which they may act, and which may connect them, as it were, with one another. Animals are actually endowed with other internal powers than those yet mentioned: they compare objects presented to them; they judge between the true and false; between nearness and distance: they distinguish between beauty and deformity; they can discern order from confusion. Their other powers furnish, as it were, the materials; these combine and separate, and arrange them. The operation of these several faculties is succeeded by the determination of the will; a power which is necessary to complete the character of a thinking, animated being. No circumstances in the situation of animals, no particulars in their form, or bodily powers, or mental dispositions, give rise to more remarkable disparities among them, than those which depend on their powers of comparing, and of judging between different objects. These hold so important a rank among the other powers, that, wherever they are in the smallest degree diversified, they produce the most remarkable diversities of character.

By their superiority in these respects the human species is eminently distinguished above the rest of the animal kingdom; so eminently, indeed, that they are the lords of all other beings, and the rest are their slaves, or unequal enemies. The same law prevails throughout all animated nature. The more perfect the powers of comparing and judging in any particular order or kind, so much the more powerful, respectable, and happy is that division. Superior address often renders a smaller and more timid animal an over-match for one that is larger, stronger, and even more ferocious.

But the inferior animals are so remarkably deficient in the reasoning and thinking powers, when compared with man, that human pride has been tempted to deny them entirely the possession of such powers. Though we find them such useful assistants, and at times such formidable enemies, we would willingly degrade them to a rank in the order of creation still lower than that which nature has assigned them. We delight to represent them as destitute of judgment, and guided only by what we call instinct. We observe that even the most sagacious among them are incapable of that variety of minute distinctions which our reasoning faculties enable us to make:—they cannot take so full a review of the past, nor look forward with so penetrating an eye towards the future: they do not accumulate observation upon observation, or add to the experience of one generation that of another: their manners do not vary, nor their customs fluctuate, like ours: their arts remain always the same, and are not liable either to degenerate, or to be improved: the crow always builds its nest in the same way; every hen treats her young with the same measure of affection; even the dog, the horse, and the sagacious elephant, seem to act rather by association than with design. From such hasty observations as these it was inferred by Descartes, that brutes are directed in their actions by some mysterious influence, which impels them to employ their powers mechanically and unintentionally in performing actions beneficial to themselves, and suitable to their nature and circumstances.

There are opposite opinions, however, that have been carried to as wide an extreme. One of the greatest philosophers among the ancients, Pythagoras, was so fully convinced that the brutes possess the same powers of intelligence as men, that he represented them to his disciples as animated by souls which had previously acted a part in human bodies, and, for that reason, enjoined them to treat those their humbler brethren with gentleness and humanity, and to beware of ever shedding their blood. The same opinion still prevails through the east: and has such an influence on the manners of the Gentoos, that they will perish of hunger rather than shed the blood or eat the flesh of an animal.

This opinion, as well as that which degrades the brutes to the low character of pieces of mere machanism, have equally originated from prejudice or careless observation. Since natural history has begun to be more diligently cultivated, innumerable observations made on the manners and œconomy of the inferior animals prove, that, if they be guided by instinct, that instinct is by no means a mechanical principle of action, but, in its nature and susceptibility of improvement, approaching nearly, in many cases, to the character of human reason. The manners of no one species among the brutes are uniformly the same in all the individuals belonging to it. Even in performing those actions in which they are said to be guided by unvarying instinct, different individuals display different modes of conduct. It is probable, that if we were to examine their manners and œconomy with the same minute and careful attention with which we observe the conduct of our own species, we should find those of their actions which we call instinctive much more diversified than we imagine: the general resemblance,—the family likeness, would no doubt still hold; but we should surely discover the character of the individual to be distinctly marked, as well as that of the species. The laws of analogical reasoning do not justify the idea that the brutes act, on any occasion, absolutely without design. In many instances they undeniably act with design: the dog obeys his master; he traces his footsteps in order to overtake him: he even attempts to make returns of gratitude for the kindness with which he is treated. Others of the inferior animals behave in a similar manner. It seems therefore more probable that such animals, even in those instances in which we cannot distinguish the motives which actuate them, or the causes by which they are instigated, act not altogether without design, and extend their views, if not a great way, yet at least a certain length forward,—than that they can be, upon any occasion, influenced by anomalous feeling, or overruled by some mysterious influence, under which they are nothing but insensible instruments.

The facts from which this induction is drawn have of late forced themselves on observation, in such a manner as to give rise to a very false theory of a kind still different: in which it has been thought better to degrade mankind nearer to the same level with the brutes, than to elevate the brutes to the rank usually assigned to mankind. The human mind has been represented as a bundle of instincts, only a little larger than those bundles of the same materials which have been bestowed on the brute creation. Observing, that the inferior animals seem, on many occasions, to act upon the same principles with mankind, and unwilling to allow that the former can ever act with design; the author of this theory has contrived to explain the phænomena by denying design to his own species.

But we will not tamely surrender our rights: we will share them with other animals rather than be entirely deprived of them. We are conscious of comparing ideas and of forming designs. If these operations be called instincts,—be it so; this is not to advance a new doctrine, but to propose the use of it in a new sense. Let mankind still be allowed to reason, and to act with design, even though it must be granted that the brutes too reason, but not so skilfully, and form designs, but designs much less extensive than those of mankind.

We not only accomplish such purposes as we propose to ourselves, by the use of such means as prudence suggests; but we are also subject to laws, by the influence of which our conduct, whatever it be, naturally produces certain effects on our character and circumstances, which we neither previously desired nor foresaw. The drunkard, for instance, sits down only to swallow a liquor of which he is fond, or to join in that noisy mirth which reigns among his fellows; but he insensibly acquires a habit which he did not think of, and by indulging in that habit, unintentionally produces very unhappy changes in his health and circumstances. The benevolent man, in the same manner, when he interferes to relieve his brother in distress, does not probably attend to all the effects which his conduct, in this instance, is likely to produce, either to himself, or to the person whom he relieves: and of human actions in general it may be observed, that their consequences always extend much farther than the design or foresight of the agent. Beings of superior intelligence might regard mankind as incapable of design, with just as much reason as we have to deny the brutes any guiding principle superior to blind and simple instinct. We, however, are conscious of design; though our designs are commonly narrow, and our views limited: why, then, consign the inferior animals, in every instance, to the guidance of an unmeaning impulse? Were it proper to enter more minutely at present into a discussion of this point, it might be easy to prove, by an induction of particulars, that brutes actually compare ideas and deduce inferences; and when we consider their docility, and mark the variety of their manners, it appears almost absurd to deny that they form designs, and look backward on the past, and forward towards the future, as well as ourselves.

We may conclude, then, with respect to inferior animals, that they possess, in general, the powers of perception, memory, consciousness; with various affections, passions, and internal feelings; and even, though perhaps in a meaner degree, those powers of comparing and judging which are necessary to enable an animated being to form designs, and to direct its actions to certain ends. Their prospects towards the future are evidently very confined: they cannot review the past with such a steady eye as man; imagination is not, with them, so vigorous and active as with us; it is limited within a much narrower range. But still they are not absolutely confined to present sensations; they connect some part of the past and of the future with the present. When we contemplate their manners, we behold not social intercourse regulated among them by the same forms as among man: their characters and circumstances differ so considerably from ours, that though the great outline of right and wrong may, wherever perceived, remain the same to them as to us; yet the application of that outline to particular cases must be very different among them from what it is with ourselves. Thus, philosophers have fancied imaginary states of human society, in which the present laws of distributive and commutative justice could not be observed: but even in such states of society, the fundamental principles of justice would continue obligatory, and would only be varied in their application. Brutes appear, in short, to possess, but in a more imperfect degree, many of the same sensitive faculties as mankind. Instinct must always be a simple principle, an original feeling; the only business of which is to rouse to action,—to call the reasoning or comparing powers to exert themselves. To talk of instinctive principles that admit of improvement, and accommodate themselves to circumstances, is merely to introduce new terms into the language of philosophy. No such improvement or accommodation to circumstances can ever take place without a comparison of ideas, and a deduction of inferences. When we consider with how much difficulty that acquaintance with the manners and customs of mankind, which we call knowledge of the world, is obtained, we cannot be surprised that even philosophers should be so imperfectly acquainted with the more minute particulars in the manners and œconomy of the brutes. To man their manners are much less interesting than those of his own species; and there are, besides, many difficulties to prevent us from becoming intimately acquainted with them, however earnestly we may turn our attention to this object.

If to these powers by which animals are so eminently distinguished above the species of the vegetable and the mineral kingdom, we add the peculiarities of their form, of the structure of the interior parts, and of their exterior covering,—the happy adaptation of all their organs to the purposes for which they seem intended by nature,—and the wise provision by which they are enabled to continue their kind; we cannot but consider them as constituting by far the most eminent order among the works of creation. They alone are capable of happiness. The rest of the universe seems to be intended for their accommodation. The enjoyments which they are formed to receive, the duties which they are destined to fulfil, and the laws by which the duty and the happiness of all animals are so closely connected, afford the most eminent proofs of the perfection of the divine nature, that the works of creation exhibit. The inferior parts of nature are beautiful, or grand, or regular, only in proportion as they are formed to excite certain sentiments in the minds of animated, thinking beings; at least, were they not calculated to contribute to the happiness of such beings, by communicating to them agreeable sentiments, their order, magnificence, and beauty, would be lost, or incapable of serving any visible end.

Yet all this has no possible connexion with the possession of an accountable and immortal principle. Matter and spirit are equally the works of the Creator, and perhaps equally created out of nothing—for we have no more reason beyond what our own pride would suggest to us, to conceive that spirit is an emanation or extension of the essence of the Creator than that matter is. Each of them, therefore, as the works of an omnipotent and benevolent Creator, is entitled to reverence. Brutes are not immortal, for they have no principle that is designed to be so: but till it be demonstrated that the plastic substance of matter, admitted to be capable of instinct, is necessarily and absolutely incapable of consciousness, memory, reflexion, and judgment, the experienced train of facts daily and hourly starting around us should reasonably induce us to believe them possest of these internal senses in conjunction with mankind, though in a far subordinate and less perfect degree.

Natural history, then, comprises in its general scope the history of minerals, plants, and animals: the first of which differ from the two last by being produced fortuitously, growing by external accretion, or the mere juxtaposition of new matter alone; and being only capable of destruction by mechanical or chemical force: while the other two, on the contrary, are produced by generation, grow by nutrition, and are destroyed by death; are actuated by an internal power, and possessed of parts mutually dependent, and contributory to each others functions.

But while animals and vegetables thus agree in their general characters, they also possess features of distinction which it is never difficult to lay hold of, excepting in the few anomalous cases to which we have already adverted. While both agree in an origin by generation, growth by nutrition, and a termination by death; in an organized structure, and an internal living principle, they differ in the power with which the living principle is endowed, and the effects it is capable of exerting. In the plant it is limited, so far as we are capable of tracing it, to the properties of mere irritability and contractility: in the animal it superadds to these properties those of muscularity, sensation, and voluntary motion.

Animals differ from animals in the greater or less perfection with which the faculties connected with sensation are allotted to them. Man differs from, and is raised above the whole, by the possession of a rational and immortal spirit.

The various classifications under which these departments are usually considered, are best discussed under the separate articles of the departments themselves. We have therefore already noticed plants under BOTANY, and fossils under MINERALOGY, and shall reserve the classification of animals for ZOOLOGY: while the present article may be regarded as a general introduction to the whole.

NATURAL HORIZON, is the sensible or physical horizon.

NATURAL MAGIC, is that which only makes use of natural causes; such as the Treatise of J. Bapt. Porta, Magia Naturalia.

NATURAL PHILOSOPHY, otherwise called **PHYSICS**, is that science which considers the powers of nature, the properties of natural bodies, and their actions upon one another. See PHILOSOPHY, PHYSICS, NEWTONIAN, ELECTRICITY, MAGNETISM, &c.

NA'TURAL. *s.* (from *nature.*) 1. An idiot; a fool (*Shakspeare. Locke*). 2. Native; original inhabitant (*Raleigh*). 3. Gift of nature; quality (*Wotton*).

NATURAL, in music. See MUSIC.

NA'TURALIST. *s.* (from *natural.*) A student in physics, or natural philosophy (*Addison*).

NATURALIZA'TION. *s.* (from *naturalize.*) The act of investing aliens with the privileges of native subjects (*Bacon*). Hereby an alien is put in the same state as if he had been born in the king's ligeance, except only, that he is incapable of being a member of the privy council, or parliament, and of holding any office or grant. No bill for a naturalization can be received in either house of parliament without such disabling clause in it; nor without a clause disabling the person from obtaining any immunity in trade thereby in any foreign country, unless he shall have resided in Britain seven years next after the commencement of the session in which he is naturalized. Neither can any person be naturalized, or restored in blood, unless he have received the sacrament within one month before the bringing in of the bill, and unless he also take the oaths of allegiance and supremacy in the presence of the parliament. See ALIEN.

To **NA'TURALIZE.** *v. a.* (from *natural.*) 1. To invest with the privileges of native subjects (*Davies*). 2. To make easy like things natural (*South.*).

NA'TURALLY. *ad.* (from *natural.*) 1. According to unassisted nature (*Law*). 2. Without affectation (*Shakspeare*). 3. Spontaneously; without art.

NA'TURALNESS. *s.* (from *natural.*) 1. The state of being given or produced by nature (*South.*). 2. Conformity to truth and reality; not affectation (*Dryden*).

NA'TURE. *s.* (*natura*, Latin.) 1. An imaginary being supposed to preside over the material and animal world (*Cowley*). 2. The native state or properties of any thing, by which it is discriminated from others (*Hale*). 3. The constitution of an animated body (*Shakspeare*). 4. Disposition of mind; temper (*Shakspeare*). 5. The regular course of things (*Shakspeare*). 6. The compass of natural existence (*Glanv.*). 7. The constitution and appearance of things (*Reynolds*). 8. Natural affection, or reverence (*Pope*). 9. The state or operation of the material world (*Pope*). 10. Sort; species (*Dryden*). 11. Sentiments or images adapted to nature, or conformable to truth and reality (*Addison*), 12. Physics (*Pope*).

Thus again, according to Mr. Boyle, nature has eight different significations; it being used, 1. For the author of nature, whom the schoolmen call Natura Naturans, being the same with God. 2. By the nature of a thing we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we say, that a stone by nature falls to the earth. 5. Sometimes we understand, by nature, the established course of things. 6. Sometimes we take nature for an aggregate of powers belonging to a body, especially a living one; in which sense physicians say, that nature is strong, weak or spent; or that, in such or such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phœnix, or chimera, that there is no such thing in nature. 8. Sometimes too, and that most commonly, we express by the word nature a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature, less ambiguous than those already mentioned, and with regard to which many axioms relating to that word may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world in its present state, considered as a principle; by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things. And this makes way for the other subordinate notion; since the particular nature of an individual consists in the general nature applied to a distinct portion of the universe; or, which is the same thing, it is a particular assemblage of the mechanical properties of matter, as figure, motion, &c.

> “Nature is but a name for an effect
> Whose cause is God.” COWPER.

Nearly conformable with this sentiment of the poet is the language of M. Haüy, who says, “This word, nature, which we so frequently employ, must only be regarded as an abridged manner of expressing sometimes the results of the laws to which the Supreme Being has subjected the universe; at others, the collection of beings which have sprung from his hands. Nature, contemplated thus under its true aspect, is no longer a subject of cold and barren speculation with respect to morals: the study of its productions, or of its phenomena, is no longer bounded to enlightening the mind; it affects the heart, by kindling therein sentiments of reverence and admiration at the sight of so many wonders, bearing such visible characters of an infinite power and wisdom. Such was the disposition that was cultivated by the great Newton, when, after having considered the mutual connection which subsists between effects and their causes, which makes all the particulars concur to the harmony of the whole, he elevated his mind to the idea of a Creator and Prime Mover of matter, and enquired of himself why nature had made nothing in vain? whence it happens that the sun, and the planetary bodies, gravitate the one towards the other, without any intermediate dense matter? and, how it could be possible that the eye should be constructed without the knowledge of optics, or the organ of hearing without the intelligence of sounds? See the Introduction to Haüy's Natural Philosophy, translated by Gregory.

NATURE (Laws of), are certain axioms, or general rules, of motion and rest, observed by natural bodies in their actions upon one another. Of these laws, sir I. Newton has established three. See AXIOMS.

NATU'RITY. *s.* (from *nature.*) The state of being produced by nature: not used (*Brown*).

NA'VAL. *a.* (*naval*, Fr. *navalis*, Latin.) 1. Consisting of ships (*Waller*). 2. Belonging to ships (*Temple*).

NAVAL ARCHITECTURE. See SHIP-BUILDING.

NAVAL CAMP, in antiquity, a fortification, consisting of a ditch and parapet on the land side, or a wall built in the form of a semicircle, and extended from one point of the sea to another. This was sometimes defended with towers, and beautified with gates, through which they issued forth to attack their enemies. Homer hath left us a remarkable description of the Grecian fortifications of this sort, in the Trojan war, beginning at v. 436. Iliad *η*.

> Then, to secure the camp and naval powers,
> They rais'd embattled walls with lofty tow'rs:
> From space to space were ample gates around,
> For passing chariots; and a trench profound,
> Of large extent; and deep in earth below
> Strong piles infix'd stood adverse to the foe.
> POPE's Transl.

NAVAL CROWN, among the ancient Romans, a crown adorned with figures of prows of ships, conferred on persons who in sea engagements first boarded the enemy's vessel. See CROWN.

NAVAL STORES, comprehended all those particulars made use of, not only in the royal navy, but in every other kind of navigation; as timber and iron for shipping, pitch, tar, hemp, cordage, sail-cloth, gunpowder, ordnance, and fire-arms of every sort, ship-chandlery wares, &c.

NAVAL TACTICS, the military operations of fleets. See TACTICS (Naval).

NAVAN, a borough, post, and fair town of Ireland, in the county of Meath and province of Leinster; situated about 23 miles north-west of Dublin, on the river Boyne. It consists of two chief streets, which intersect each other at right angles. The Tholsel, or town-house, is a handsome stone building. This place was formerly in great repute, and walled by Hugh de Lacy. An abbey for regular canons, dedicated to the Virgin Mary, was erected here; but whether antecedent to the end of the 12th century is not certain.

NAVARINO, a strong and populous town of the Morea, with an excellent large harbour, defended by two forts. It is seated on a hill, near the sea, eight miles N.E. of Modon, and 17 N.W. of Coron. Lon. 21. 40 E. Lat. 37. 2 N.

NAVARRE, a kingdom of Europe, lying between France and Spain, and divided into the Upper and Lower. The Upper belongs to Spain, and is 75 miles in length and 60 in breadth. The air is more mild, temperate, and wholesome than in the neighbouring provinces of Spain; and, though a mountainous country, it is fertile, abounding in all sorts of game, and in iron mines. It is divided into five districts, whose capital towns are Pampeluna, Estella, Tudela, Olita, and St. Guesca. Lower Navarre belongs to France, and is now the department of the Lower Pyrenees. It is separated from Spanish Navarre by the Pyrenees, and is a mountainous, barren country, 20 miles in length and 12 in breadth. From this country the late king of France took his other title of king of Navarre. See PALAIS, ST.

NAVARRE (Peter), a warrior in the 16th century, born in Biscay. After being a seaman, he entered into the service of cardinal Aragon as valet, and next served in the army of the Florentines, and then engaged in the sea service. He was employed by Gonsalvo de Cordova in the Neapolitan wars, as captain, and he contributed much to the taking of Naples. The emperor gave him the domains of Alveto, in Naples, from which he assumed the name of Navarre. He afterwards sailed against the Moors of Africa, and took possession of Oran, Tripoli, and other places; but part of his army was defeated by the Moorish cavalry. His campaigns in Italy afterwards were unfortunate, and he was taken at the battle of Ravenna, 1512. The ill treatment of the Spanish king determined him to enter into the service of Francis I. In his attempt to relieve Genoa he was taken by the imperial troops, and for three years languished in the dungeons of Œuf, till the treaty of Madrid set him free. He was taken prisoner at the retreat of Aversa, and again sent to the dungeons of Œuf. Here his life was spared by the duke of Orange, in compassion for his misfortunes and his valour. He died soon after; though some assert that he was strangled in his bed.

NAUCORIS, in the entomological system of Fabricius, a tribe of the genus NEPA, which see.

NAUCRATIS, a city of Egypt, on the left side of the Canopic mouth of the Nile, celebrated for its commerce. No ship was permitted to land at any other place, but was obliged to sail directly to the city, there to deposit its cargo.

NAUDE (Gabriel), was descended from a good family, and born at Paris, February 12, 1600. His parents observing his fondness for reading and inclination to letters, resolved to breed him in that way; and accordingly sent him to a religious community, to learn the first rudiments of grammar and the principles of christianity. Thence he was removed to the university, where he applied himself with great success to classical learning; and having learned philosophy, was created master of arts very young. As soon as he had finished his course in philosophy, he remained some time at a stand what profession to choose, being advised by his friends to divinity; but his inclination being more turned to physic, he fixed at length upon that faculty. However, this choice did not prevent him from indulging his genius in other branches of learning: in reality, the plan of his studies was very extensive, suited to his comprehensive talents and indefatigable industry: and he soon distinguished himself therein so much, that Henry de Mesmes, president à mortier, hearing his character, made him keeper of his library, and took him into his family. Naude was the more pleased with this post, as it gave him an opportunity of gratifying his bookish taste in general, and at the same time furnished him both with means and leisure to improve himself as he could wish, in the science which he had embraced in particular. He quitted it in 1626, in order to go to Padua to perfect himself therein: but he did not continue long in that university, the death of his father and his domestic affairs calling him back to Paris before the expiration of the year.

In 1628 the faculty of physic appointed him to make the customary discourse on the reception of licentiates; which performance entirely answered their expectations from him, and was made public. In 1631, cardinal Bagni made him his librarian and Latin secretary, and carried him with him to Rome in the spring of that year. Naude continued in this service till the death of the cardinal, which happened July 24, 1641; and in the interim made an excursion to Padua, to take his doctor of physic's degree, in order to support with a better grace the quality with which he had been honoured by Louis XIII. who had made him his physician. The ceremony of this appointment was performed March 25, 1633, and we have the speech he pronounced on the occasion. After the death of his patron he had thoughts of returning to France; but was detained in Italy by several advantageous offers made to him by persons of consideration in that country. Among these he preferred those of cardinal Barberini, and closed with his eminence. However, as soon as cardinal Richelieu sent for him to be his librarian, he immediately returned to Paris; but he happened not to be long in the service of the prime minister, if it be true that he arrived at Paris in March 1642, since cardinal Richelieu died in December following: notwithstanding, he succeeded to the like post under Mazarine, for whom he formed a most rich library, which he raised from the first volume in the space of seven years to the number of 40,000. Christiana, queen of Sweden, who set herself to draw into her dominions all the literati of Europe, procured a proposal to be made to Naude of being her library keeper; and as he was then out of all employ, he accepted the proposal, and went to Cop. But he soon grew out of humour with his residence in Sweden: the manners of the people, so very different from his, gave him great disgust; and seeing France become more quiet than it had been, he resolved to return. Accordingly he quitted Sweden loaded with presents from the queen, and several persons of distinction: but the fatigue of the journey threw him into a fever, which obliged him to stop at Abbeville; and he died there July 29, 1653.

As to his character, he was very prudent and regular in his conduct, sober, never drinking any thing but water. Study was his principal occupation, and he was indeed a true *Helluo librorum*; so that he understood them perfectly well. He spoke his mind with great freedom, and that freedom sometimes showed itself upon religious subjects, in such a manner as might have occasioned some disadvantageous thoughts of him; but the christian sentiments in which he died led some to believe that his heart never was corrupted, and had no share in the free expressions which sometimes escaped from him; especially in the philosophical railleries which passed sometimes between him, Guy Patin, and Gassendi. He wrote a great number of books, a catalogue of which may be seen in Niceron's Memoirs, tom. ix. Voltaire says, that "of all his books, the Apologie des grands Hommes accusés de Magie is almost the only one which continues to be read."

NAUDE (Philip), well known as an able professor of mathematics at Berlin in the seventeenth and early part of the eighteenth century, was born at Metz in Lorrain, in the year 1654. At the age of about twelve he was taken into the service of the court of Eysenach, in the capacity of page, and attendant on the young princes. In this situation his behaviour secured him the esteem of all who knew him; and while he continued here he learned the German language, which afterwards proved of great use to him. When he had spent about four years at Eysenach, his father chose to take him home; but how he was employed during the next fifteen years of his life we are not informed. We are only told that his father had neither the intention nor the means of affording him a learned education; but that, notwithstanding the disadvantages of his condition, having an unconquerable thirst for knowledge, he became his own master, and made considerable proficiency in different branches of learning, particularly in the mathematical sciences. As he was in principle a protestant, when the edict of Nantes was revoked in 1685, he left France with his wife and young child, about nine months old, and resided about two years at Hanau. Hence he removed to Berlin, where he contracted an intimacy with M. Langerfield, mathematician to the court, and tutor to the pages. This gentleman, who knew how conversant he was with the sciences, advised him to open a mathematical school, and recommended pupils to him. In 1687 he received an appointment to teach arithmetic and the elements of the mathematics at the college of Joachim; and in 1690 he was made secretary interpreter. Upon the death of M. Langerfield not many years afterwards, M. Naude succeeded him in 1696, both in his employments at court, and the professorship in the Academy in Sciences. In 1701 he was elected a member of the Academy of Sciences; and in 1704, when the king founded the Academy of Princes, M. Naude was attached to it by a special patent, as professor of mathematics. He died at Berlin in 1729, at the age of seventy-five, highly respected for his integrity and general excellence of character. Though the mathematics chiefly occupied his attention, he was not unacquainted with the other sciences, and as he was zealous for the religion which he professed, he had made divinity his particular study, and written several treatises on religious and moral subjects. In mathematics, his sole publication was Elements of Geometry in quarto, written in German, and printed at Berlin for the use of the Academy of Princes; and some smaller pieces, which appeared at different periods in the Miscellanea Berolinensia. Among his theological and moral productions were, Sacred Meditations, 1690, 12mo.; Evangelical Morality, 1699, in two volumes, 12mo.; The Sovereign Perfection of God in his Divine Attributes, and the perfect Integrity of the Scriptures, in the Sense maintained by the first Reformers, 1708, in two volumes, 12mo. written against M. Bayle; which, being attacked in a 12mo. pamphlet, he defended in A Collection of Objections to the Treatise on the Sovereign Perfection of God, with Answers to the same, 1709, 12mo.; An Examination of two Treatises of M. de Placette, 1713, in two volumes, 12mo.; Dialogue in Solitude, partly translated from the Dutch of William Teelink, 1717, 12mo.; A Refutation of the Philosophical Commentary, 1718, 12mo. &c. (*British Encyclo.*)

NAVE. *s.* (nap, Saxon.) 1. The middle part of the wheel in which the axle moves (*Shakspeare*). 2. (from *navis*, *nave*, old French.) The middle part of the church distinct from the aisles or wings (*Ayliffe*).

NAVEL, in anatomy, the centre of the lower part of the abdomen; being that part where the umbilical vessels passed out of the placenta of the mother. See ANATOMY and MIDWIFERY.

NAVEL-GALL. In farriery, an injury sustained upon the centrical part of the back-bone, corresponding with the part below, whence the name. It is always occasioned by the pad of the saddle being in itself too wide (and deficient in stuffing,) letting the iron-work of the tree come into contact with the spine; or from a long and constant use of a roller in the stable, till having lost the elasticity of its stuffing, it then becomes sufficiently hard, particularly with too tight buckling, to occasion the injury; which is often productive of much trouble and vexation.

NAVELWORT (Venus's), in botany. See COTYLEDON and CYNOGLOSSUM.

NAVEW, in botany. See BRASSICA.

NAUGHT. *n.* (nahꞇ, naƿihꞇ, Saxon.) Bad; corrupt; worthless (*Hooker*).

NAUGHT. *s.* Nothing. This is commonly, though improperly, written *nought* (*Shak.*).

NA'UGHTILY. *ad.* (from *naughty.*) Wickedly; corruptly.

NA'UGHTINESS. *s.* (from *naughty.*) Wickedness; badness (*Sidney*).

NA'UGHTY. *a.* (from *naught.*) Bad; wicked; corrupt (*Sidney*).

NAUGUER, in mastiology. See ANTELOPE.

NAVICULAR VALVE. *s.* In botany. Cymbiformis valvula. A boat-shaped valve. As in isatis and thlaspi.

NAVICULARE OS. (*navicularis*, from *navicula*, a little boat). *Os scaphoides.* A bone of the carpus and tarsus is so called from its supposed resemblance to a boat. See CARPUS and TARSUS.

NAVIER (Peter Toussaint), of St. Dizier, died at Chalons-sur-Marne, 1779. He is known for his discovery of nitrous ether, and the combination of mercury with iron, hitherto regarded as impossibilities. In epidemical disorders his prescriptions were very successful; and to the truest meekness and modesty he united the highest humanity. He wrote a dissertation on common diseases—observations on the softening of the bones—reflections on the danger of hasty burials, and the abuses of interments in churches—antidotes against arsenic, 2 vols. 12mo. &c.

NA'VIGABLE. *a.* (*navigable*, French.) Capable of being passed by ships or boats (*Raleigh*).

NA'VIGABLENESS. *s.* (from *navigable.*) Capacity to be passed in vessels.

To NA'VIGATE. *v. n.* (*navigo*, Lat. *naviger*, Fr.) To sail; to pass by water (*Arbuth.*).

To NA'VIGATE. *v. a.* To pass by ships or boats (*Arbuthnot*).

NAVIGATION (*navigatio*), from *navigo*, compounded of *navis*, a ship, and *ago*, to govern or manage), the art of conducting a ship from one port to another; and comprizes the method of giving to the vessel the desired direction by means of the sails and rudder, or seamanship; as well as the mode of ascertaining the relative situation of the ship at any assigned time and the future course, so as to reach her place of destination with safety and expedition. To the latter department, however, in compliance with custom, our present researches must be limited.

The antiquity and utility of navigation are acknowledged by all; and the art was probably cultivated by several cotemporary tribes, inhabiting the sea coast, unknown to one another; if so, the circumstance accounts for different authors ascribing the invention to different persons and nations. We may however now despair of ascertaining how

> "From darkest times her humble birth she drew."

It is generally admitted that the Phœnicians were the first people who applied themselves assiduously to the cultivation of navigation, and, had they not been so extremely tenacious of the knowledge they acquired, their success might not only have been highly beneficial to the neighbouring nations, but the civilized world would have been gratified by it, and in return would have done ample justice to their genius and enterprize. However, their great arcanum, matured by the perseverance of ages, would have been lost when Alexander subdued Tyre and Sidon, on account of the illiberal jealousy with which it was concealed from the rest of the world, had not their Carthaginian descendants preserved it in a distant corner of Africa.

Alexandria, intended by its founder, not only to perpetuate his name, but likewise to be the grand emporium of the eastern and the western commerce, next "flickers through the gloom:" and in consequence of the exertions of the Alexandrians to accomplish this ample intention, navigation began to dawn in Egypt. Yet the Carthaginians, who inherited the Phœnician propensity to cultivate the art, eclipsed the Egyptians as well as the Grecians in nautical knowledge and experience, and by degrees acquired those vast resources which enabled them so long to withstand the Roman power. During the obstinate struggle between Carthage and Rome, the first germs of the art appeared in Italy.

The destruction of Carthage, and battle of Actium, consigned navigation and commerce to the Romans: when the latter was left to the exertions of subject provinces, and the former was only cultivated to aid their favourite views of universal dominion: and upon the ruin of that empire navigation shared the fate of literature and the other arts.

When the barbarian Attila destroyed Aquilea, Mantua, Treviso, Verona, and other adjacent cities, such of the inhabitants as escaped the slaughter fled to the islands of their coast, where they took up their residence, and founded Venice. Here navigation and commerce revived from the general wreck, and passed successively to the Genoese, Hans Towns, Portuguese, Spaniards, English, and Dutch.

Still navigation was very imperfect, although the improvements made in the sails and rigging had superseded the rowers; and the mariner's compass, invented about 1260, had encouraged the navigator to launch boldly into the watery expanse: yet geometry, trigonometry, and astronomy, which constitute the ground-work of the method whereby the mariner discovers his situation, were not sufficiently matured to be subservient to his purpose: but, about this period, while he was traversing the pathless ocean, or exploring unknown shores, the student was no less assiduous to enrich the haven-finding art with his researches: and the application of the mathematical sciences, with the invention of suitable and accurate instruments, soon enabled the navigator to determine his situation with tolerable precision.

Perhaps the progress of navigation has not been equal to that of the other arts, which may be owing to the seaman's confidence in the methods sanctioned by those he reverences, accompanied by an inability to comprehend how a landman should improve his art: be this as it may, the comparative perfection to which navigation is arrived, is more particularly attributable to the genius and labours of Mr. Edward Wright, Mr. James Gregory, and Dr. Edmund Halley, who perfected Mercator's chart, and pointed out true methods of computing the longitude from the dead reckoning; John Napier, baron of Merchiston, and Mr. Henry Briggs, who invented and perfected the logarithms; James Hadley, esq. who published the quadrant that bears his name, and the rev. Dr. Maskelyne, under the commissioners of longitude, who devised and established the nautical almanac.

The authors who have written upon navigation are numerous, both in England and upon the continent; yet if we except an ingenious treatise upon the longitude by Dr. Andrew Mackay, and the valuable tables for navigation and nautical astronomy, by Joseph de Mendoza Rios, esq. every thing of any moment in the various volumes may be found in Mr. John Robertson's excellent treatise. These, with the Nautical Almanac, Requisite Tables, and British Mariner's Guide, by Dr. Maskelyne, may be considered a complete library for a navigator.

Having taken a cursory retrospect of the slow and now obscure steps by which navigation attained its present modification, we proceed to develope the principles upon which the navigator founds the computations which ascertain the ship's relative position; and, at the same time, from those principles to deduce the modes of calculation.

1. When a ship begins a voyage, the first thing which presents itself to the computist is to ascertain the distance, or space passed over in some determinate time, for which purpose half a minute is usually assumed for the unit of time, and a proportionate segment of a meridian for the unit of space, which last dimension is called a knot. The mutual relation being so adjusted, that for every knot of the log-line which is run out in half a minute, so many miles does the ship sail in an hour, admitting her velocity continues uniform for that space of time; but this, together with currents and heave of the sea, the judicious navigator will take into consideration.

Comparing the results of various mensurations, the length of a degree in these latitudes appears to be about 365244 feet, see Phil. Transa. for 1795, p. 491; therefore a nautical mile is $= \frac{365244}{60} = 6087{\cdot}4$ feet, and consequently the space corresponding to half a minute in time $= \frac{6087.4}{60 \times 2} = 50{\cdot}725$ feet, or 50 feet 8¾ inches nearly, which ought to be the length of a knot, could the distance sailed be accurately measured: but the drift of the log, with the surface of the water in the direction of the wind; the weight of the line, and the friction of the reel, all tend to render the distance, as given by the log, less than it ought to be: for this reason, and likewise because it is safest to have the reckoning a-head of the ship, competent judges divide their line into knots of 48 feet, and allow half a second for turning the glass after the stray line is out, or, which amounts to the same thing, use glasses which run out in 29½″. In short, the result of this fundamental operation is very uncertain, and a method free from the respective defects of such as have been proposed, is a desideratum in navigation.

Cotton lines have been recommended, and particularly adopted, as being less liable to vary in length; but the extension of hempen lines by draught, and contraction by moisture, is much too considerable to be neglected by the navigator; besides which, the temperature of the atmosphere may affect the glass to about one-sixth of the whole time of running out. It is therefore highly requisite to examine both line and glass, from time to time, and if either or both be found erroneous, the true distance may notwithstanding be obtained.

For, putting $G = 30''$, $g =$ the time measured by the erroneous glass, $K = 48$ feet, $k =$ the length of an inaccurate knot, and $D =$ the computed distance the ship has sailed during the time the error is admitted to have existed. Then,

(1) When the glass is found inaccurate, and the line correct.

Because the excess or defect of D will be directly as g, it will be as $g : D :: G : \frac{DG}{g} = \frac{30D}{g}$, the true distance.

Ex. The distance run by the log is 80 miles, and the glass is found to run out in 24″. Required the true distance?

Here $\frac{30 \times 80}{24} = 5 \times 20 = 100$ miles, the true distance.

(2) When the line is inaccurate and the glass correct.

The error in the distance will be reciprocally as the excess or defect of the line, therefore $K : k :: D : \frac{kD}{K} = \frac{kD}{48}$ the true distance.

Ex. The distance run is 150 miles, and the length of the knot 45 feet. Required the true distance?

Here $\frac{45 \times 150}{48} = 140{\cdot}625$ miles, the true distance.

(3) When both the glass and line are found to be inaccurate.

By compounding the foregoing analogies $g : D :: G : \frac{DG}{g} =$ the distance corrected for error in glass, and $K : k : \frac{DG}{g} : \frac{DGk}{gK} = \frac{30Dk}{48g} = \frac{5Dk}{8g}$ or $\frac{10Dk}{16g}$, the true distance.

Ex. The distance sailed by the log is 200 miles, the glass runs 33″, and the knot measures 42 feet. Required the true distance?

Here $\frac{5 \times 200 \times 42}{8 \times 33} = 159.09$ miles, the true distance.

2. The course a ship steers is ascertained by the mariner's compass (see Compass). But as the magnetic north seldom coincides with the true, in order therefore to determine the angle which the ship actually makes with the meridian, it is requisite that the deviation or variation of the points of the compass from the corresponding points of the horizon should be known.

To illustrate the methods of solving this important problem, let Fig. 1. Pl. 114. be a stereographic projection of the sphere on the plane of the horizon, the north, east, south, and west points of which are represented by N.E. S.W. respectively, Z being the observer's zenith, P the elevated pole, Σσς a parallel of declination, Σ the true place of the sun at rising, and Σ′ his place as pointed out by the compass at the same moment.

Then is EΣ the true amplitude, EΣ′ the magnetic amplitude, and ΣΣ′, their difference, the variation. Now, in order to determine EΣ, and finally ΣΣ′ from the latitude of the ship, and the declination of the sun, which are the customary data: in the quadrantal spheric triangle PEΣ, PΣ = the sun's polar distance, and the angle PEΣ = the latitude are given. As it would be extraneous to investigate formula, which decidedly belong to another department of science, we therefore refer to any of the numerous treatises on the theory of trigonometry, where it will be found demonstrated that cosine PEΣ : cosine PΣ : : radius : sine EΣ the amplitude, or cosine ΣN the azimuth; hence 10 + logar. cos. PΣ + comp. log. cos. PEΣ = log. sine ΣE: But the log. secant — 10 = the complement of the logarithmic cosine, therefore log. cos. PΣ + log. sec. PEΣ = log. sine EΣ.

That is, The logarithmic sine of the true amplitude is equal to the sum of the logarithmic sine of the declination and logarithmic secant of the latitude.

Example. July 24th, 1810, in latitude 50° N. longitude 35° W. about a quarter after four o'clock A.M. the sun was observed to rise E.N.E., allowance being made for semi-diameter. Required the variation?

Sun's declination July 24th, at noon	19° 59′		
Equation to $7\frac{3}{4}$ hours from noon +	4 4		
to 35° W.	1 3		
Reduced declination	20° 2	Sine	9·5347452
Latitude	50	Secant 10	·1919325
True amplitude EΣ	E. 32 12¼ N.	Sine	9·7266777
Magnetic amplitude EΣ′	E. 22 30 N.		

Variation - - - - 9 42½ West, because the magnetic place of the sun is more distant from the north than the true, the observation being made in the eastern hemisphere.

Were greater accuracy required, the horizontal refraction, parallax, height of the eye, and latitude of the ship, ought to be taken into account, which would render the triangle oblique: therefore to obviate their effects, let the amplitude be observed when the altitude of the sun's lower limb is = 15′ + the dip of the horizon. For instance, if the height of the eye be 20 feet, the amplitude ought to be observed when the altitude of the sun's lower limb is 19½ minutes.

When clouds or haze render this mode of solution impracticable, the mariner obtains the magnetic azmiuth SZσ by observation, as before, and deduces the true azimuth SZσ from the latitude, sun's altitude, and declination: having in the spheric trangle σPZ, PZ = the complement of the latitude, and σZ, σP the sun's zenith and polar distances respectively, to find the azimuth or angle SZσ; the logarithmic sine of the half of which is (by trigonometry) = $\frac{1}{2}$ (log. sine $\frac{1}{2}$ (Pσ + D) + log. sine $\frac{1}{2}$ (Pσ — D) + log. secant PZ + log. secant Zσ — twice the radius). D being = Zσ — ZP.

Ex. July 25th, 1810, in latitude 31° 30′ N. longitude 34° 10° E. a little after 7 o'clock A.M. the altitude of the sun's lower limb was 23° 20′, and bearing per compass E. 5° 20 S. height of the eye 21 feet. Required the variation?

Sun's declination July 25th, at noon	19° 47′ N.	Observed altitude of the sun's l. l.	23° 20′
Equation to 5 hours	— 2½	Semidiameter	+ 16
to 23° 20′ E.	+ 1	Dip and refraction	— 6½
Reduced declination	19 45½	True altitude	23 29½
Polar distance	70 14½	Zenith distance	66 30½

Co-latitude	PZ	58″ 30	cosecant — radius	,0692342
Zenith distance	Zσ	66 30½	cosecant — radius	,0375748
D		8 0½		9·8000282

Many other methods of obtaining the variation might be adduced, but these two are accurate, easy, and sanctioned by custom; and we would not draw the attention of navigators to inventions which have little to recommend them but their novelty.

3. Having developed the methods of estimating the course and distance, we shall now assume these as data, and proceed to investigate the mode of obtaining from them the relative position of the ship.

But before the line described by a ship, upon the surface of the ocean, with its concomitant incidents can be subjected to calculation, its nature and properties must be known: to form a correct idea of which, conceive

(1.) First, that the port B bears due north or south from A; if therefore the line which joins those points be produced, it will pass through the poles of the world, and consequently the ship which sails in a direct line from A to B, or *vice versa*, describes part of a meridian.

2. If B bears due east, or west from A, and they are equi-distant from the poles of the world, they are consequently upon the equator: but if the polar distances of the parallel on which they are situate be unequal, the line joining them is parallel to the equator or a parallel of latitude, and therefore perpendicular to the meridians: hence, the ship which sails due east or west will intersect the meridians at right angles, and either describe a portion of the equator, or of a circle parallel to it.

(3.) If the line joining A and B neither coincide with a meridian nor cut it at right angles:—for instance, if A be the Lizard, and B the island of Barbadoes, which bear S.W. and N.E. from one another: a ship which sails in a direct course from the former to the latter will not only steer S.W. when she begins her voyage, but likewise continue S.W. or cut every meridian at an angle of 45° during her progress: consequently, while the course continues invariable, the ship makes equal angles with all the meridians she meets on the surface of the ocean:—and because her track is described upon a spherical surface, it is not a straight line: nor is it a circle; for an oblique circle described upon the surface, of the earth makes unequal angles with all the meridians. (See PROJECTION OF THE SPHERE): it is therefore requisite,

4. (I). To investigate the nature and properties of the line, described upon the surface of the earth, which cuts all the meridians at equal angles.

Let PQW (Fig. 2. Pl. 114.) represent part of a stereographic projection of the sphere on the plane of the equator, and let the curve QAFOP intersect the equidistant meridians PR, PS, PT, PV, PW, making the angle PEF = PCF = PHF = PAF = PQF. Then, because in every stereographic projection the lines intersecting each other form angles, equal to the angles upon the sphere which they represent; the curve QAFP is the representation of the track of a ship which cuts all the meridians in the angle PQF.

Now, in the equiangular, and consequently similar, triangles, PAQ, PHA, &c. to PFE, it will be PQ : PA : : PA : PH : : PH : PC : : PC : PE : : PE : PF; hence PQ, PA, &c. to PF are in geometrical proportion, while the corresponding arcs QR, RS, &c. to V ware (by hypothesis) in arithmetical proportion: therefore, the latter are the logarithms of the former; that is, QR is the logarithm of the ratio of AP to QP, ow the logarithm of the ratio of PF to PQ, and so on: consequently, the curve QAFP is the logarithmic spiral or nautical rhumb-line.

5. Let PG be perpendicular to PA, and through the point A at which the curve intersects PR draw AG, making the ∠ PAG equal to that which the rhumb-line makes with the meridians: then will the line AG coincide with an indefinitely small part of the curve at A, and consequently be a tangent to it at that point.

Admit that the meridians PR, PS, &c. to PW, are indefinitely near to each other; and from the points H, C, E, F, upon PA, PH, PC, PE, demit the perpendiculars H*e*, C*f*, E*g*, F*h*: then, by similar triangles, A*e* : AH : : H*f* : HC : : C*g* : CE, &c. : : (12 E . V), A*e* + H*f* + C*g* + &c. (= AP) : AH + HC + CE + &c. (= the curve AFOP) : : AP : AG; whence by equality, the infinite rhumb AFOP is equal to the finite right line AG.

Let FL be a tangent at the point F, and meet PL drawn perpendicular to PF in L; then, it may be shewn in the same manner, that the rhumb FOP is equal to the right line FL.

6. Now the right-angled triangles APG, FPL, having the angle PAG in the one equal to PFL in the other, are similar, therefore PA : PF : : AG (AOP) : FL (FOP), or by division, PA : PA — PF (AN) : : AG : AG — FL (AOP — FOP = AF), and alternately PA : AG (: : cos. of angle PAG : radius) : : AN : AF.

But AN is equal to the difference of the latitudes of the points A and F, AF the length of the rhumb intercepted between those points or distance and the angle PAG, which the rhumb makes with the meridians, is the course:

Hence radius : cosine of the course : : the distance : difference of latitude.

Therefore, if a right-angled triangle ANF (Fig. 3.) be constructed, in which the hypothenuse AF is equal to the distance run; the angle at A equal to that which the rhumb makes with the meridians, or course, and the perpendicular AN equal to the difference of the latitudes left and come to: any two of these being given, the third may be accurately determined by the above specified analogy; and that whether the earth be a sphere, spheroid, or any other regular solid formed by revolving about its axis: but the third side FN or departure remains to be considered.

This is called plane sailing, from the common supposition of its being performed upon a plane: and the six cases of a plane right-angled triangle constitute all the varieties it admits of. See Dr. Hutton's Mathematical and Philosophical Dictionary, under SAILING.

When the course, distance, and latitude left are given, the parallel of latitude the ship is upon at any assigned time may be found by plane sailing: but as it is likewise requisite for the mariner to know upon what meridian he is at the same time, because the intersection of those circles determines his situation; and as plane sailing makes no provision for this purpose, we must necessarily prosecute our inquiries.

If the ship sail upon a parallel of latitude, AB (Fig. 2.), this is, due east or west:—let P (Fig. 4.) be the pole; IBD a section parallel to the equator QWLC; PR, PW meridians intercepting AB a segment of a parallel of latitude. Then CR, CW, and DA, DB being drawn, the points CWR, DBA being respectively in the same planes, and those planes parallel to one another, the lines WR, WC, CR and AB, BD, DA are therefore respectively parallel, and the angles WCR, BDA consequently equal: hence, by similar sectors,

AD, the cosine of the latitude AR
is to AB, the distance sailed,
as RC, the radius of the equator
to RW the difference of longitude:

Which is the property of a right-angled plane triangle ABC (Fig. 5.), in which the hypothenuse AC represents the difference of longitude, the perpendicular CB the distance, and the angle at C the latitude of the parallel. This, from the manner in which it is performed, is denominated PARALLEL SAILING, and the varieties or cases which it admits of are,

(1.) Cosine of the latitude : distance :: radius : difference of longitude.

(2.) Radius : difference of longitude :: cosine of the latitude : distance.

(3.) Difference of longitude : radius :: distance : cosine of the latitude.

Let ENF be a section parallel to DAB, then CW : WR :: DB : BA :: EF : FN; therefore

(4.) Cos. lat. A : cos. lat. N :: segment AB : segment FN, and

(5.) Segm. AB : segm. FN :: cosine of latitude A : cos. lat. N.

Example. The longitude of the Borlings (near Lisbon) is 9° 37′ W., that of Baltimore 76° 55′ W, and their common latitude is 39° 20′ N. Required their distance?

Longitude of Baltimore	-	76° 55′ W.	
Longitude of the Borlings	-	9 37 W.	
Difference of longitude	-	67 18	= 4038
Radius - -	s. 90°	-	10·000000
Into cosine of latitude	-	39° 20′	9·88844
As the difference of longitude		4038	3·60617
To the distance 3123¼ miles		-	3·49461

7. Suppose the ship sails upon a rhumb towards the pole, or from A to F (Fig. 2.). The sum of all the intermediate parallels He + Cf + Eg + Fh will be the departure; FN the meridional distance, which in this case is less than the departure; and RW the difference of longitude; hence the departure, meridional distance and difference of longitude are all different: if she sail in the opposite direction, or from F to A, the departure and difference of longitude will be the same as before, but the meridional distance is now AB, a quantity greater than the departure: consequently, the departure made in the voyage from A to F or from F to A being the same, and consisting every where of quantities equidifferent, the extremes of which are as AB to FN; the sum of all the departures (provided each of them is indefinitely small) will therefore be a mean between AB . FN; or XY, the corresponding parallel or mean arc of the middle latitude be equal to ½ (AB + FN) which therefore will nearly represent the whole departure of the voyage between A and F.

Hence, by parallel sailing, RW : AB :: Radius : cosine of AR
and RW : FN :: Radius : cosine of NR;

therefore, by equality of ratios and composition, radius : ½ (cos. AR + cos. NR) :: difference of longitude RW : departure XY, or, because the cosine of RX is nearly equal to ½ (cos. AR + cos. NR) we obtain this fundamental theorem, radius : cosine of the middle latitude RX :: difference of longitude : departure.

This is called MIDDLE-LATITUDE SAILING, and the several cases which it admits of are readily solved by connecting the triangles of the plane and parallel sailing, so that the departure may be common to both. (See Fig. 6.).

For, in the triangle FCN, radius : cos. mid. lat. :: diff. long. : departure,
And, in the triangle FNA, radius : tang. course :: diff. lat. : departure;
Therefore by equality (1.) Diff. long. : diff. lat. :: tang. course : cos. mid. lat.
(2.) cos. mid. lat. : tang. course :: diff. lat. : diff. long.
(3.) Tang. course : cos. mid. lat. :: diff. long. : diff. lat.
And because the sides are as the sines of their opposite angles,
(4.) Sine course : cos. mid. lat. :: diff. long. : distance.
(5.) Distance : diff. long. :: cosine mid. lat. : sine course.
(6.) Diff. long. : distance :: sine course : cos. mid. lat.

For an example—Suppose a ship from Oreby-point in latitude 58° 35′ N. and longitude 6° 37′ W. sails N. 67′ easterly, 2649 miles. Required the latitude and longitude come to?

To find the difference of latitude.

Radius - -	-	-	10·0000000
Is to cosine of course	67°	-	9·5918780
As the distance	2649′	-	3·4230820
To the diff. of lat.	1035′	-	3·0149600
Lat. of Oreby-point	58° 35′ N.		58° 35′
Diff. of latitude	17 15 N.	half	8 37½
Latitude come to	75 15 N.	mid. lat.	67 12½

To find the difference of longitude.

Cosine of mid. lat.	67° 12½	co. log.	0·4116608
Is to sine of course	67°	-	9·9640261
As the distance	2649′	- -	3·4230820
To the diff. of long.	6291¾′	-	3.7987689
Longitude of Oreby-point	-	-	6° 37 W.
Difference of longitude	-	-	104 51¾ E.
Longitude come to	-	-	97 14¾ E.

8. Could the latitude of that parallel whose arc is equal to the departure be conveniently obtained to a tolerable degree of accuracy, and were the arithmetical mean of the cosines of the two distant latitudes equal to the cosine of their arithmetical mean; these researches might end with middle-latitude sailing, and a true chart would complete this department of navigation. Having however seen that the former is not the case, and that the latter is not yet attained, we shall at present reserve our opinion of middle-latitude sailing, and proceed,

9. To inquire in what manner the surface of the earth be delineated upon a plane, so that the relative position of places be preserved, and the necessary nautical computations performed by plane trigonometry.

In Fig. 4. let PQC be a quadrant of the sphere whose radius is CQ; PQ, PW meridians, EK the radius of a lesser circle parallel to the equator LWQ, and QAF a rhumb.

Suppose Qkfw a segment of a cylinder formed by perpendiculars erected at every point of the equatorial arc WQ, and admit the spherical qua-

Fig. 5.

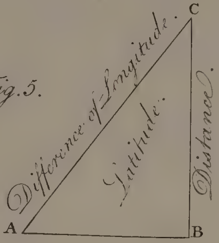

Fig. 6.

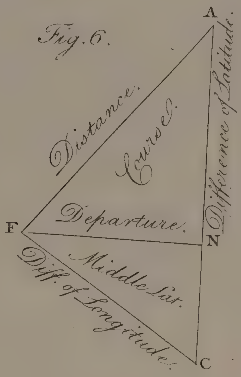

Fig. 8.

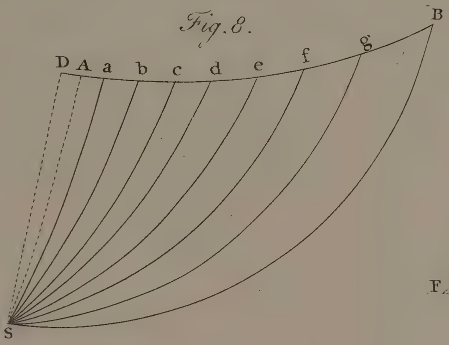

Fig. 7.

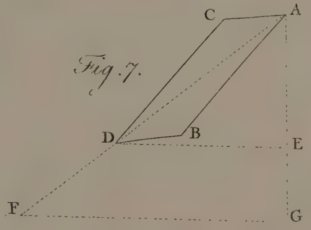

Fig. 9.

Publish'd by G. Kearsley Fleet Street, March 1.1811.

drilateral QKFW projected thereon by rays issuing from C the centre of the sphere.

Now $\mathrm{Q}k$ is parallel to $\mathrm{w}f$ by hypothesis, and it is obvious that fk, the projection of FK, is a circular arc parallel and equal to WQ:

If therefore the figure $\mathrm{Q}kf\mathrm{W}$ be extended into a plane, and turned about $\mathrm{Q}k$ as an axis until QW coincide with CQ produced, it will be a rectangular parallelogram $\mathrm{Q}kf'\mathrm{W}'$—and the triangle QFK projected into $\mathrm{Q}fk$, in which kf is equal to QW'.

But KF : QW :: EK (the cosine of the latitude QK) : CQ (the radius of the sphere) :: CK = CQ : Ck (the secant of the latitude.)

Hence, in the projection, FK, the segment of a parallel of latitude is protracted in the proportion of the secant of the latitude to radius, consequently, to obtain similiarity $\mathrm{Q}k$ must be increased in the same proportion.

For this purpose, from centre C with radius Ck describe the ark $k\mathrm{s}$, intercepted by QW', make $\mathrm{Q}\varkappa$ equal to the arc $k\mathrm{s}$, let $\varkappa\varphi'$ be drawn parallel to kf' until it meet $\mathrm{W}'f'$, produced in φ', and join $\mathrm{Q}\varphi'$.

Then by similar segments $\mathrm{QK} : sk = \mathrm{Q}\varkappa :: \mathrm{CK} = \mathrm{CQ} : \mathrm{C}k$.

Hence $\varkappa\varphi' = kf' : \mathrm{KF} :: k\mathrm{C} : \mathrm{KC} :: \mathrm{Q}\varkappa = sk : \mathrm{QK} :: \mathrm{Q}\varphi' : \mathrm{QF}$, therefore the right-angled triangle $\mathrm{Q}\varkappa\varphi'$ on the plane, is proportional to the mixtilineal triangle QKF on the sphere, and consequently the relative position of places on both are identical.

10. Conceive the meridian PR drawn indefinitely near to PW, and a the projection of the point A, where it cuts the rhumb, through a draw an arc parallel to the equator and to the point i, where it meets $\mathrm{Q}\varphi$ draw $\mathrm{C}i$; let the arc is be described from centre C, and $\mathrm{Q}\iota$ made equal to is.

Then, by similar sectors, $\mathrm{C}i : \mathrm{CQ} :: \mathrm{CI}\ (\mathrm{CQ}) : \mathrm{ID} :: \mathrm{QR} : \mathrm{IA} :: \dot{\overline{\mathrm{QR}}}\ (\mathrm{WR})\ \frac{\mathrm{CQ}}{\mathrm{C}i} = \mathrm{QR}\ (= \mathrm{AB}) = \dot{\overline{\mathrm{IA}}}$; and, $\mathrm{CQ} : \text{tang. AQI} :: \dot{\overline{\mathrm{QI}}}\ (\mathrm{BF}) : \dot{\overline{\mathrm{IA}}} = \frac{\mathrm{CQ}}{\mathrm{C}i} \times \dot{\overline{\mathrm{QR}}}$; therefore $\dot{\overline{\mathrm{QR}}} = \frac{\text{tang. AQI} \times \dot{\overline{\mathrm{QI}}} \times \mathrm{C}i.}{\mathrm{CQ}^2}$

But $\mathrm{CI} : \mathrm{CQ} :: is\ (\mathrm{Q}\iota) : \mathrm{QI} :: \dot{\overline{\mathrm{Q}\iota}} : \dot{\overline{\mathrm{QI}}}$, hence $\mathrm{C}i \times \dot{\overline{\mathrm{QI}}} = \mathrm{CQ} \times \dot{\overline{\mathrm{Q}\iota}}$, therefore $\dot{\overline{\mathrm{QR}}} = \frac{\text{tang. AQI} \times \dot{\overline{\mathrm{Q}\iota}},}{\mathrm{CQ}}$ and consequently $\mathrm{QR} = \int \frac{\text{tang. AQI} \times \dot{\overline{\mathrm{Q}\iota}}}{\mathrm{CQ}} = \frac{\text{tang. AQI} \times \mathrm{Q}\iota:}{\mathrm{CQ}}$

Whence $\mathrm{CQ} : \text{tang. AQI} :: \mathrm{Q}\iota : \mathrm{QR}$.

And for the same reason $\mathrm{CQ} : \text{tang. AQI} :: \mathrm{Q}\varkappa : \mathrm{QW}$.

Hence by equality $\mathrm{Q}\varkappa, : \mathrm{Q}\iota :: \mathrm{QW} : \mathrm{QR}$,

And by division and alternation $\mathrm{Q}\varkappa : \mathrm{QW} :: (\mathrm{CQ} : \text{tang. AQI} = \mathrm{FAN} ::)\ \mathrm{Q}\varkappa - \mathrm{Q}\iota\ (= \iota\varkappa = \acute{\alpha}\nu') : \mathrm{QW} - \mathrm{QR}\ (\acute{\nu}\varphi')$; which analogy is applicable to the right-angled plane triangle $\alpha\nu'\varphi'$, having an angle $\nu'\alpha\varphi'$ equal to that which the rhumb makes with the meridians or course, the adjacent side $\nu'\alpha\varphi$ = the protracted or meridional difference, and the opposite side $\nu'\varphi'$ equal to the difference of longitude. This triangle is therefore similar to a triangle $\alpha m\pi$ constructed with the course $m\alpha\pi$, and proper difference of latitude αm, agreeably to the property developed in art. 6; and consequently the homologous sides will be proportional.

This ought to be called Wright's sailing, but Mercator's is the only appellation it has hitherto borne, and imperious custom compels us to retain it. The cases or variations it admits of are, first, in the triangle $\alpha\nu'\varphi'$.

(1) Rad. : tang. course :: meridional diff. lat. : diff. longitude.

(2) Rad. : cotang. course :: diff. long. : merid. diff. latitude.

(3) Merid. diff. lat. : diff. long. :: radius : tangent of the course.

Secondly in the triangle $\alpha m\pi$. See art. 6.

(4) Radius : cosine course :: distance : diff. latitude.

(5) Radius : secant of the course :: diff. lat. distance.

(6) Dist. : diff. of lat. :: radius : cosine of the course.

The departure is an unnecessary, and in most cases an improper, datum, but were it admitted we should further have

(7) Proper diff. lat. : merid. diff. lat. :: departure : diff. longitude, with its varieties; and the triangle $\alpha m\pi$ would have three cases in addition to those exhibited above.

Referring to the example in art. 8, and having determined the latitude come to as therein specified, in order to find the difference of longitude we have,

Latitude of Oreby-point - - -	58° 35′	mer. pts. 4361
Latitude come to - - -	75 50	7167
Meridional difference of latitude - - - - - -		2808
Radius - - - - - -		10·0000000
Is to the tangent of the course - -	67°	10·3721481
As meridional diff. of lat. - -	2808	3·4483971
To the diff. of longitude - - -	6615¼	3·8205452

Longitude of Oreby-point - - - - - - -	6° 37′ W.
Difference of longitude 6615¼ m. = - - -	110 15¼ E.
Longitude come to - - - -	103 38¼ E.,

whence it appears, that the ship arrived at Cape Cevero Vostochnoi in Asiatic Russia: but by middle latitude sailing she was 6° 23′½ to the westward of that cape, which shews, that the mode of computing the longitude by middle-latitude sailing is very erroneous, particularly at a distance from the equator.

11. It is now manifest that when the difference of longitude is one of the data, a table of the lengths of the protracted meridians or meridional parts, to every degree and minute of the quadrant, is necessary, to facilitate the computations in Mercator's sailing: and such a table may be computed with ease:

For $\mathrm{DI} : \mathrm{CQ} :: \dot{\overline{\mathrm{QI}}} : \frac{\mathrm{CQ}}{\mathrm{DI}} \times \dot{\overline{\mathrm{QI}}} = \dot{\overline{si}} = \dot{\overline{\mathrm{Q}\iota}} :: \dot{\overline{\mathrm{CD}}} : \dot{\overline{\mathrm{QI}}} = \frac{\mathrm{CQ}}{\mathrm{DI}} \times \dot{\overline{\mathrm{CD}}}$, hence $\dot{\overline{\mathrm{Q}\iota}} = \frac{\mathrm{CQ}^2}{\mathrm{DI}^2} \times \dot{\overline{\mathrm{CD}}} = \frac{\mathrm{CQ}^2 \times \dot{\overline{\mathrm{CD}}}}{\mathrm{CQ}^2 - \mathrm{CD}^2}$, and therefore $\mathrm{Q}\iota = \int \frac{\mathrm{CQ}^2 \times \dot{\overline{\mathrm{CD}}}}{\mathrm{CQ}^2 - \mathrm{CD}^2} =$

$\text{CQ} \times \text{hyp. log.} \left(\frac{\sqrt{\text{CQ}+\text{CD}}}{\text{CQ}-\text{CD}}\right) = \text{CQ} \times \text{H.L.} \left(\frac{\text{cotangent } \frac{1}{2}\text{ IP}}{\text{CQ}}\right)$.

To obtain $Q\iota$ in terms of the tabular logarithms in which the ratio of 10 to 1 is expressed by 1000000000, it is to be recollected that in the hyperbolic system the same ratio is expressed by 2302585092, &c.; therefore, 2302585092 : 1000000000 :: H. L. $\left(\frac{\text{cot.} \frac{1}{2}\text{IP}}{\text{CQ}}\right)$: tab. log. $\left(\frac{\text{cot.} \frac{1}{2}\text{IP}}{\text{CQ}}\right)$; consequently, $\text{CQ} + \text{H.L.} \left(\frac{\text{cot.} \frac{1}{2}\text{IP}}{\text{CQ}}\right) = \text{CQ} \times 2{\cdot}302585092 \times \log. \left(\frac{\text{cot.} \frac{1}{2}\text{IP}}{\text{CQ}}\right)$. And, to reduce this expression to minutes of a degree, which is the most convenient form for practice, the well-known ratio of the circumference of a circle to its radius gives this proportion 6·283185307 : 1 :: 21600′ (360°) : 3437·746770849 minutes in the radius CQ.

$$\text{Consequently, } Q\iota = 3437{\cdot}746770849 \times 2{\cdot}302585092 \times \log. \left(\frac{\text{cot. } \frac{1}{2}\text{ IP}}{\text{CQ}}\right)$$

$$= 7915{\cdot}704468046 \times \log. \left(\frac{\text{cot. } \frac{1}{2}\text{ IP}}{\text{CQ}}\right) = \frac{1}{{\cdot}00012633114387} \times \log. \left(\frac{\text{cot. } \frac{1}{2}\text{ IP}}{\text{CQ}}\right)$$

$$= \frac{10000000\ ^{*}}{1263{\cdot}3114387} \times \log. \left(\frac{\text{cot. } \frac{1}{2}\text{ IP}}{\text{CQ}}\right)$$

Example. If it were required to find the length of the protracted meridian, or meridional parts for 50°:

Log. cotangent of $\left(\frac{90° - 50°}{2}\right)$	20° —	10·4389341		
Logarithm of the radius CQ	- -	10·0000000		
Difference × 10000000 =	- - - -	4389341	its log. is - -	6·6424000
Logarithm of the constant number	- -	1263·3114387	- -	3·1015104
Protracted meridian for 50° =	- -	3474·481	- - - -	3·5408896

Thus may the lengths of the protracted meridians be determined to every subdivision of the quadrant; and when computed and arranged for the seaman's use, is called a Table of Meridional Parts.

That such a table is not absolutely necessary will obviously appear if we put R = the logarithm of the radius, T, t = the logarithmic cotangents of half the complements of the latitudes QI. QK respectively, and δ = the constant quantity ·00012633114387 :— because then $\frac{\text{T}-\text{R}}{\delta} = Q\iota$, and for the same reason $\frac{t-\text{R}\ \dagger}{\delta} = Q\varkappa$; therefore the meridional difference of latitude $\iota\varkappa = Q\varkappa \pm Q\iota = \frac{t \pm \text{T}}{\delta}$ *.

Now we have seen (art. 10.) that CQ : tang. AQI :: $\iota\varkappa = \alpha\nu'$: $\nu'\varphi'$; that is, radius : tang. course :: mer. diff. lat. $\left(\frac{t \pm \text{T}}{\delta}\right)$: diff. of long. which analogy gives $\nu'\varphi' = \frac{\text{tang. AQI} \times \alpha\nu'}{\text{CQ}} = \frac{\text{tang. AQI} \times (\pm \text{T}}{\text{CQ} \times \delta}$; therefore, the complement of the log. of the constant quantity δ + log. $(t \pm \text{T})$ + log. tang. course — log. radius = logarithm of the difference of longitude.

Taking the former example,

½ co. lat.	C. Cevero Vostochnoi	7° 5′ log. cot.	10·9056645			
	Oreby-point -	15 42½ log. cot.	10·5509164	complement of const. log.		6·8984896
	Difference $(t - \text{T})$	- -	3547481	its logarithm	-	6·5499202
	Log. tangent of the course 67°		-	-	-	10·3721481
	Log. of the difference of longitude 6615·4 = 110° 15′ 4				-	3 8205579

Consequently, the meridional parts may not only be readily deduced from a table of logarithmic tangents, but the latter is fully competent to supply the place of the former.

The cases or varieties in the protracted triangle $\alpha\nu'\varphi'$ are:

(1). Tangent of the course $= \frac{\nu'\varphi' \times \text{radius} \times \delta}{(t \pm \text{T}.)}$.

(2). Difference of longitude $\nu'\varphi' = \frac{\text{tang. course} \times (t \pm \text{T})}{\text{CQ} \times \delta}$.

(3). Mer. diff. of lat. $(t = \text{T}) = \frac{\nu'\varphi' \times \text{CQ} \times \delta}{\text{tang. course}}$.

12. As an investigation of the nature of the rhumb when transferred from the sphere to Mercator's chart may be justly deemed an inferior concern; yet, as it may gratify the young inquirer, and tend to illustrate and extend these researches, we shall just glance at its chief properties.

We have seen (art. 10.) that $\overline{\text{QR}} = \frac{\text{tang. AQI} \times \text{C}i \times \overline{\text{CI}}}{\text{CQ}^2}$, but (Crackelt's translation of Mauduit's Trigonometry, chapter V.

---

* It is here admitted that the radius of the table is 10000000, but when it is 1000000, 100000, &c. the constant denominator will become 126·33114387, 12·633114387, &c.

† Minus, when the latitudes are of the same name, but plus when of contrary names.
